FPL has identified the property adjacent to the existing FPL Corbett Substation property in unincorporated western Palm Beach County as a preferred site for the addition of new generating capacity. The preferred site was evaluated for the addition of a new combined cycle natural gas power plant project with ultra low sulfur distillate as a backup fuel. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections. The proposed facility would use natural gas as the primary fuel and state-of-the-art combustion controls.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the West County Energy Center site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The land on the site is currently inactive but was previously dedicated to industrial and agricultural use. The site has been excavated, back-filled, and totally re-graded to an elevation approximately 10 ft. above surrounding land surface. No structures are present on the site and vegetation is virtually non-existent.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

The majority of the plant site has been significantly altered by the construction and operation of a limestone mine where vegetation had been cleared and removed. Most of the remaining site property has been previously altered through development for agricultural use and rock mining. The surrounding land use is predominantly sugar cane agriculture and limestone mining. The FPL Corbett substation is located north of the site. The Arthur R. Marshall Loxahatchee National Wildlife Refuge is located to the south of the site.

2. **Listed Species**

Construction and operation of new units at the site is not expected to affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the mining activities. Common wading birds can be observed on areas adjacent to and occasionally within the property. The property is adjacent to areas that have been identified as potential habitat for wood stork.

3. **Natural Resources of Regional Significance Status**

The construction and operation of a gas-fired combined cycle generating facility at the site is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands including the Arthur R. Marshall Loxahatchee National Wildlife Refuge which lies south of the proposed location. It is not anticipated that construction will result in wetland impacts under federal, state or local agency permitting criteria.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The current design option is to construct two new 1,100 MW (approximate) units each consisting of four new CT's, four new HRSG's, and a new steam turbine. The site has sufficient capacity to construct an additional 1,100 MW unit in the future if needed. The first and second units are planned to be placed into service in mid-2009 and mid-2010, respectively. Natural gas delivered via pipeline is the primary fuel type for this unit with ultra low sulfur distillate serving as a backup fuel.

g. Local Government Future Land Use Designations

Local government future land use designation for the project site is "Rural Residential" according to the Palm Beach County Future Land Use Map. Designations for the area under the Palm Beach County Unified Land Development Code classified the project site and surrounding area as Special Agricultural District. The site has been granted conditional use for electrical power facilities under a General Industrial zoning district.

h. Site Selection Criteria and Process

The site has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. This site is considered permittable.

i. Water Resources

The existing adjacent surface water canal, reservoir, and available ground water resources are potential sources for potable and service water for the proposed units. Use of water from the upper and/or lower Floridan Aquifer is also considered a feasible alternative as potential backup sources of water for operation of the proposed units.

j. Geological Features of Site and Adjacent Areas

The site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, clay, and phosphate grains. The deepest formation in Palm Beach County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Oldsmar formation. The published information on the sediments comprising the formations below the Avon Park Limestone is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach Counties.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for industrial processing is 300 gallons per day (gpd) for uses such as process water and service water. Approximately 25 million gallons per day (mgd) in total of cooling water for the two proposed units would be cycled through the addition of cooling towers. Water quantities needed for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l. Water Supply Sources by Type

The proposed units will use available surface or ground water as the source of service water and makeup water for the cooling towers. Potable water needs will be met through the use of the surficial aquifer.

m. Water Conservation Strategies Under Consideration

Impacts on the surficial aquifer would be minimized and used only for potable water. The plant site will capture and reuse process water whenever feasible and manage stormwater in such a manner so as to recharge the surficial aquifer.

n. Water Discharges and Pollution Control

Heated water discharges will be dissipated in the cooling towers. Blow down from the cooling towers will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Industrial discharges will be minimized by treating and recycling equipment wash water, boiler blowdown water, and equipment area runoff. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. The facility will employ a Best Management

Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is not located near an existing natural gas transmission pipeline that is capable of providing a sufficient quantity of gas. Upgrades of existing pipelines and/or lateral connections to other pipelines will be necessary for supply of natural gas. Ultra low sulfur distillate would be received by truck and stored in above-ground storage tanks to serve as backup fuel for the new units.

p. Air Emissions and Control Systems

The use of natural gas and ultra low sulfur distillate as fuels, plus combustion controls, will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using natural gas and ultra low sulfur distillate as fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra low sulfur distillate as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the West County Energy Center units will incorporate features that will make them among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by construction of the units at the site is expected to be below current noise levels for the residents nearest the site. Noise from the operation of the new units will be within allowable levels.

r. Status of Applications

An SCA will be filed in 2005 for the construction and operation of the West County Energy Center project under the Florida Electrical Power Plant Siting Act. A PSD permit application and an underground injection control permit application will also be submitted to the FDEP at the same time.

IV.F.2 Potential Sites for Generating Options

Seven (7) sites are identified as "Potential Sites" for near-term future generation additions to meet FPL's capacity needs.[1]

These sites have been identified as Potential Sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these potential sites offer advantages and disadvantages relative to engineering considerations and/or costs associated with the construction and operation of feasible technologies. In addition, each potential site has different characteristics that could require further definition and attention. For discussion purposes, it was assumed that natural gas-fired technologies would be the likely capacity additions at the Potential Sites unless otherwise indicated.

Permits are presently considered to be obtainable for all of these sites, assuming measures can be taken to mitigate any particular site-specific environmental

[1] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites.

concerns that may arise. No significant environmental constraints are currently known for any of these 7 sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time FPL considers each site to be equally viable.

Potential Site # 1: Andytown Substation , Broward County

FPL has identified the FPL Andytown Substation property in western unincorporated Broward County as a potential site for the addition of new generating capacity. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. U.S. Geological Survey (USGS) Map

A USGS map of the potential site has been included at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land uses for the site are designated as industrial or agricultural use. The site identification process included screening of potential sites to determine potential wetland impacts and impacts to endangered or threatened species. Extensive low-quality wetlands are adjacent to the site. FPL would expect to mitigate any impacts from construction of a power plant at this site. Construction and operation of a new facility on this site is not expected to adversely affect any rare, endangered, or threatened species.

d. and e. Water Quantities and Supply Sources

Surface water sources are not available at the site. Groundwater from the shallow aquifer or a local source of gray water have been identified as potential water sources. The Floridan Aquifer has been identified as a potential cooling water source. It has been estimated that sufficient water is available for generation technologies that might be considered for the site.

Potential Site # 2: Cape Canaveral Plant, Brevard County

This potential site is located on the FPL Cape Canaveral Plant property in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway (US 1). A rail line is located near the plant. The existing facility consists of two 400 MW (approximate) steam boiler type generating units.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Cape Canaveral property site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

This site is located on the Indian River. The land is primarily dedicated to industrial use with surrounding grassy areas and a few acres of remnant pine forest. The land adjacent to the site is dedicated to light commercial and residential use. There are no significant environmental features on the site.

d. and e. Water Quantities and Supply Sources

It is expected that industrial cooling water needs could be met using the current 550,000 gpm once-through cooling water quantity. For industrial process water, FPL would use existing on-site wells or local gray water. It has been estimated that sufficient water is available for generation technologies that might be considered at the site.

Potential Site # 3: Desoto County Site

This site is an undeveloped site located on a 13,500 acre property in unincorporated Desoto County. The site is adjacent to portions of the Peace River. There are no current facilities on the site. The City of Arcadia is located southwest of the Desoto site.

a. U.S. Geological Survey (USGS) Map

A USGS map of the potnetial site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is currently dedicated to agricultural use (sod farming, cattle grazing, and truck crops). Developed portions of the adjacent properties are primarily agricultural (sod farms, citrus groves, and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and a few isolated wetlands.

d. and e. Water Quantities and Supply Sources

The primary water source would either be groundwater from the upper and lower Floridan Aquifer or if available and practicable, a local source of gray water. Other facility water uses may include irrigation, potable use, etc., which could be supplied from shallower wells using the surficial aquifer. It has been estimated that sufficient water is available for generation technologies that might be considered for the site.

Potential Site # 4: Fort Myers Plant Site, Lee County

This potential site is located on FPL's existing 460-acre Fort Myers property. Located on the site is one 1,400 MW (approximate) combined cycle unit, Unit # 2, and 12 gas turbines each with a capacity of approximately 54 MW. Two additional simple cycle peaking units have been recently completed at the site in 2003.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Fort Myers plant site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is currently dedicated to industrial use with surrounding grassy and landscaped areas. Much of the site has recently been used for direct construction activities. The adjacent land uses include light commercial and retail to the east of the property, and some residential areas located toward the west. Mixed scrub with some hardwoods can be found to the east and further south.

d. and e. Water Quantities and Supply Sources

The available water source is the Caloosahatchee River and the available groundwater source is the Sandstone Aquifer. It has been estimated that sufficient water is available for generation technologies that might be considered for the site.

Potential Site # 5: Port Everglades Plant, Broward County

This site is located on the 94-acre FPL Port Everglades plant site in Port Everglades, Broward County. The site has convenient access to State Road (SR) 84 and Interstate 595. A rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (approximate) and two 400 MW (approximate) sized units. The four steam boilers are capable of firing residual fuel oil, natural gas, or a combination of both. The site also is home to twelve simple cycle gas turbine (GT) peaking units of 30 MW (approximate) each. The GT's are part of the Gas Turbine Power Park that is made up of 24 GT's at the Lauderdale Plant site and the twelve GTs at the Port Everglades site. The GT's are capable of firing either natural gas or liquid fuel.

a. U.S. Geological Survey (USGS) Map

A map of the Port Everglades plant site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on this site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

d. and e. Water Quantities and Supply Sources

FPL expects to use the existing municipal water supply for industrial process and makeup water. Cooling water would be drawn from the Intra-Coastal Waterway and cooling towers would be constructed. It has been estimated that sufficient water is available for generation technologies that might be considered for the site.

Potential Site # 6: Riviera Plant, Palm Beach County

This site is located on the FPL Riviera Plant property in Riviera Beach, Palm Beach County. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (approximate) steam boiler generating units and one retired 50 MW generating unit.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Riviera plant site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is primarily covered by the existing generation facilities with some open, maintained grass areas. There is a small manatee viewing area on the site, which is operated seasonally by FPL. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development. The site is located on the Intra-Coastal Waterway near the Lake Worth Inlet.

d. and e. Water Quantities and Supply Sources

The existing municipal water supply would be used for industrial processing water and FPL would continue to use Lake Worth as a source of water for once-through cooling water. It has been estimated that sufficient water is available for generation technologies that might be considered for the site.

Potential Site # 7: Southwest St. Lucie County Site

This site is an undeveloped site located in the southwest corner of St. Lucie County. A rail line, a natural gas pipeline, and electrical transmission lines are located near the site. The site is considered as suitable for the construction and operation of electrical generating facilities using a variety of technologies utilizing solid, liquid, or natural gas fuels.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Southwest St. Lucie County site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is currently dedicated to agricultural use. Most of the site is currently in use for agricultural purposes. Developed portions of the adjacent properties are primarily agricultural (cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and some wetlands.

d. and e. Water Quantities and Supply Sources

Nearby surface water are available for use at this site. Additional water sources include groundwater from the shallow aquifer, the deeper Floridan Aquifer, or if available and practicable, a local source of gray water. It has been estimated that sufficient water is available for generation technologies that might be considered for the site.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance which is available to the FPL system and the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new units that may not adversely impact such limitations. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations, and by, evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system. Both site- and system-related transmission costs are developed for each different unit/unit location option or groups of options.

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's transmission plans are presented in Section III.E.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.
2

No sensitivity case analyses based on different load forecasts were carried out during FPL's most recent planning work. This is due to the fact that the construction options projected for the earliest need years of 2009 and 2010 are combustion turbine-based combined cycle (CC) technology. If higher–than–projected loads begin to appear, the combustion turbine components of the CC options could be placed in service early in simple cycle mode. FPL believed that this fact qualitatively enables it to be able to address higher-than-projected loads. If lower-than-projected loads appear, these additions can be delayed.

[2] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases (as in FPL's current resource planning work), FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its base case or "Most Likely" fuel price forecast are discussed in Chapter III of this document.

FPL also conducted an analysis of the comparative economics of a plan that included coal-fired generation compared to an all gas-fired plan. In this study FPL utilized high, low, and expected or "most likely" fuel cost forecasts to explore the relative system fuel cost differences between a clean coal plan and a plan that included all gas-fired generation additions. This approach allowed FPL to examine the relative economics of these two different types of plans with fuel cost forecasts that varied the price difference between coal and natural gas. The results of the analyses using these different fuel cost values for coal-fired and gas-fired options is detailed in FPL's *Report on Clean Coal Generation*, presented to the Commission on March 10, 2005.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item # 3, FPL used three fuel forecasts in the comparative economic analysis of clean coal generation. FPL held the coal prices constant, based on the most likely coal price forecast, and developed three natural gas price forecasts (high, low, and expected). The low gas price sensitivity, when compared to the coal price forecast, results in an essentially fixed differential between natural gas prices and coal prices.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 and Schedule 8 present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add over the planning horizon is presented on the Schedule 9 forms

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

The key financial assumptions used in FPL's most recent resource planning work were a 45% debt and 55% equity FPL capital structure, projected debt cost of 7.1%, and an equity return of 12.0%. These assumptions resulted in a weighted average cost of capital of 9.8% and an after-tax discount rate of 8.57%. FPL did not test the sensitivity of its resource plan to varying financial assumptions.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). However, in its most recent planning work, FPL utilized both a levelized system average rate perspective for its DSM Goals and DSM Plan work and the equivalent present value of system revenue requirements perspective when evaluating options that did not result in changes to system DSM levels. (As discussed in response to Discussion Item # 2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective are identical when DSM levels are unchanged between competing plans.)

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two system reliability criteria in its resource planning work. One of these is a minimum 20% Summer and Winter reserve margin. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the planning criteria established by the North American Electric Reliability Council (NERC) in its *Planning Standards*. FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Planning Standards* are available on the internet (http://www.nerc.com).

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Facility Rating Methodology* document that are also available on the internet (http://floasis.siemens-asp.com/OASIS/FPL/INFO.HTM).

The normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95	1.05
230	0.95	1.06
500	0.95	1.07

There may be isolated cases for which FPL may determine it prudent to deviate from the general criteria stated above. The overall potential impact on customers and the probability of an outage actually occurring, as well as other factors would influence the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption are revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. Finally, FPL is careful to claim only program savings for the average life of the installed efficiency measure. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

Among the strategic or non-price factors FPL typically considers when choosing between resource options are the following: (1) fuel diversity; (2) technology risk; (3) environmental risk and (4) site feasibility.

Fuel diversity relates to two concepts, the diversity of sources of fuel (e.g., coal vs. oil vs. natural gas), and the diversity of supply for a single fuel source (for example alternative pipeline suppliers for natural gas). All other factors being equal, supply options that increase diversity in fuel source and/or supply would be favored over those that do not.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts. Technologies regarded as more acceptable from an environmental perspective for a plan are those which minimize environmental impacts through highly efficient fuel use and state of the art controls (e.g. clean coal technologies versus conventional pulverized coal).

Site feasibility assesses a wide range of economic, regulatory and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed, elements of FPL's capacity additions include the construction of new generating capacity at three existing sites: Martin, Manatee, and Turkey Point. These three generation construction projects were selected after evaluating competing bids received in response to three Request for Proposals (RFP's) issued by FPL in mid-2001, mid-2002, and mid-2003 respectively. The decision to construct new combined cycle units at FPL's existing Martin and Manatee sites was subsequently approved by the Florida Public Service Commission (FPSC) in late 2002. The FPSC approved FPL's decision to construct the new combined cycle unit at FPL's existing Turkey Point site in June 2004.

FPL plans to meet its 2008 need with a new short-term purchase agreement from Reliant's Indian River facility. In addition, a 2010–2015 purchase agreement with Southern Company was acquired and has been approved by the FPSC in January 2005.

The construction capacity additions projected in this document for 2009 and beyond will be conducted in a manner consistent with the Commissions Bid Rule through a Request for Proposal (RFP) process. Specifically, FPL intends to publish an RFP in the Summer of 2005 to solicit competitive proposals for comparison to its Next Planned Generating Unit(s) for the capacity need required in the years 2009-2011. In addition, FPL plans to publish a Clean

Coal RFP on or before August 2006 for the capacity need required in the years 2012-2014. It is anticipated that since this Clean Coal RFP is being initiated with a lead time that will support the longer construction schedule of a clean coal plant, this RFP would be restricted to proposals that provide fuel diversity comparable to that of a large coal-fired facility.

Identification of self-build options for 2009 and beyond in FPL's Site Plan is not an indication that FPL has pre-judged any capacity solicitation it may conduct. The identification of future capacity units is required of FPL and represents those alternatives that appear to be FPL's best, most cost-effective self-build options at this time. FPL reserves the right to refine its planning analyses and to identify other self-build options. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an RFP is issued for supply-side resources, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

FPL plans to construct a new transmission line (by December 2005) that is presently being certified under the Transmission Line Siting Act (403.52–403.536, F.S.). The new line will connect FPL's Orange River Substation to FPL's Collier Substation (as shown on Table III.F.1). The certification process for this new line should be completed by the summer of 2004. The construction of this line is necessary to serve existing and future customers in the Collier and Lee County areas in a reliable and effective manner. Additionally, FPL has identified the need for a new 230kV transmission line (by December 2008) that requires certification under the Transmission Line Siting Act (403.52–403.536, F.S.). The new line will connect FPL's St. Johns Substation to FPL's proposed Pringle Substation (also shown on Table III.F.1). The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and a disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (FAC).

This Ten Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2005 and that were on-going in the first quarter of 2006. The forecasted information presented in this plan addresses the 2006–2015 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten-year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's IRP process and outlines FPL's projected resource additions, especially new power plants, as determined in FPL's IRP work in 2005 and early 2006.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as preferred and potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional specific information that is to be included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2006 Ten Year Power Plant Site Plan (Site Plan) addresses FPL's plans to increase its electric generation capability as part of its efforts to meet its projected incremental resource needs for the 2006-2015 time period.

In response to strong population growth, FPL's total generation capability is required to increase significantly during the 2006-2015 time period as shown in Table ES.1. The table reflects FPL's planned changes to existing generation units (due to unit overhauls, etc.), scheduled changes in the delivered amounts of purchased power, and the planned additions of new generating units. Although not explicitly shown in this table, FPL's demand side management (DSM) resources are included. These resources incorporate the approved DSM Goals (that are assumed to be implemented on schedule) and additional DSM (identified in late 2005/early 2006) scheduled to be implemented in 2006 through 2008.

During the summer of 2005, FPL experienced a season with a significant number of peak demand events, several of which exceeded the forecasted peak demand for the year. Further investigation and review identified that population growth above that forecasted was the primary driver for this increased peak demand. In November of 2005, FPL issued an updated forecast incorporating these changes. The updated load forecast resulted in earlier and greater resource needs, with the first year of resource need moving forward to 2006 from 2009 (as had been identified in the 2005 Site Plan). In response to this emergent need, FPL is implementing additional cost-effective DSM and securing new near-term firm power purchases. It is expected that the combination of these new power purchases and additional DSM will effectively meet the incremental capacity need in 2006 and 2007, and will significantly reduce FPL's 2008 resource needs. FPL's remaining 2008 resource needs will be met by either additional near-term purchases, capacity increases to FPL's existing units, by the construction of one unsited new combustion turbine (CT) or some combination of all of these alternatives.

In 2007, FPL will be adding a new (1,144 Summer MW) combined cycle (CC) unit at its existing Turkey Point plant site. This unit was selected as the best option after comparison to other FPL construction alternatives and outside proposals received in response to an RFP that FPL issued in August 2003. This capacity addition was approved by the Florida Public Service Commission (FPSC) on June 18, 2004. FPL's application for certification under the Florida Electric Power Plant Siting Act was approved by the Governor and Siting Board on February 7, 2005.

FPL currently projects to meet its 2009 and 2010 capacity needs with the addition of two highly efficient 1,219 Summer MW CC units identified as West County Energy Center Units #1 and #2 (West County Units #1 and # 2). The first of these units is scheduled to come in service in June 2009 and the second is scheduled to come in service in June 2010. These units were selected after comparing them to bids received in response to an RFP issued by FPL in September 2005 that requested bids for firm capacity in the 2009-2011 time frame. The addition of these units, which is needed to maintain system reliability, was shown to be more than $750 million (CPVRR) more cost-effective than other alternatives received in response to the RFP. The units will effectively address the pressing need for generation located in southeast Florida to meet regional growth. As a result of their location, these units help to reduce transmission losses for the entire system. Additionally, using state of the art technology, these units will significantly increase the overall generation efficiency of the system which will result in using less fuel to produce each megawatt hour of electricity. FPL recently has filed a petition for a Determination of Need for these two units. A decision from the FPSC is expected before the end of 2006.

The addition of West County Units #1 and #2 will meet FPL's 2009 and 2010 capacity needs; however as a result of the updated load forecast, a resource need for 2011 will remain. FPL will seek to address this 2011 need with additional cost-effective DSM, power purchases, capacity increases to FPL's existing units, construction of new CTs or a combination of these resources. For purpose of this planning document, FPL projects the construction of two unsited CTs.

FPL plans to meet the need in years 2012 and 2013 with two new supercritical pulverized coal (SCPC) units. These units are scheduled to be in service by June 2012 and June 2013, respectively. A site for these two co-located, advanced coal units has not yet been selected; however, FPL is investigating suitable locations that will be identified in an addendum to this Site Plan, expected by June 1, 2006. These planned increases in electric generation capability will allow FPL to continue to maintain system reliability and integrity at a reasonable cost, and to increase fuel diversity.[1]

FPL is currently examining a variety of options to meet the remaining portion of the 2014 and 2015 need including: additional DSM, new/extended purchases and capacity enhancements to existing FPL units. Also under consideration is the construction of CT's or smaller CC units that could be designed to facilitate a conversion to coal gasification operation. For purposes of this planning document, FPL projects the construction of one additional unsited CT in 2014, one additional unsited CT in 2015, and one unsited 2x1 CC in 2015; any of which could be converted to coal gasification when the technology is shown to meet reliability and cost-effectiveness standards. The amount of capacity needed and the technologies that would ultimately be chosen to meet the need for these years will be based on FPL's ongoing review of technology, environmental requirements, regulation and economic factors and will not be restricted to a single technology.

FPL's ongoing planning efforts remain influenced by two recurrent issues. Those two issues are: 1) maintaining an appropriate balance between load and generating capacity located in Southeast Florida; and 2) maintaining and enhancing fuel diversity in the FPL system. The addition of West County Units #1 and #2 will help maintain a balance of generation located within reasonable proximity to the increasing load in the Southeast area, as well as contribute to the overall system reliability. The significant weather events of 2004 and 2005 have underscored the

[1] Repowering of existing FPL sites remains an alternative to new construction and FPL will continue to examine this, and other options including solid fuel options.

value of a balanced fuel supply as it impacts both fuel supply reliability and system fuel costs. FPL continues to actively pursue advanced technology coal generation as the most certain

alternative to measurably increase fuel diversity within the Site Plan planning horizon. FPL also has begun the steps to investigate the next generation of nuclear generation facilities. FPL is involved in several industry consortiums and has held extensive discussions with the leaders in the design, construction and operation segments of the nuclear industry to obtain an updated view of the issues surrounding adding nuclear generation in Florida. Many uncertainties remain at this early stage. However, while the feasible horizon for new nuclear generation is beyond the planning horizon of this Site Plan, FPL is actively pursuing the possibility of new nuclear generation.

Table ES.1: Projected Capacity Changes and Reserve Margins for FPL [1]

Projected Capacity Changes and Reserve Margins for FPL [1]

		Net Capacity Changes (MW)		FPL Reserve Margin (%)	
		Winter[2]	Summer[3]	Winter	Summer
2006	Changes to Existing QF Purchases [4]	(132)	(136)	25.9%	**19.5%**[8]
	Changes to existing Units	205	142		
	Changes to Non-QF Purchases [5]	147	440		
2007	Turkey Point Unit #5 [6]	—	1,144	24.2%	21.3%
	Changes to existing Units	70	77		
	Changes to Non-QF Purchases [5]	73	(412)		
2008	Changes to existing Units	4	12	26.6%	**19.3%**[8]
	Turkey Point Unit #5 [6]	1,181	—		
	Unsited Combustion Turbine [6]	—	160		
	Changes to Non-QF Purchases [5]	(252)	—		
2009	Changes to Existing QF Purchases [4]	—	(51)	23.6%	21.4%
	Changes to Non-QF Purchases [5]	(326)	(105)		
	West County Unit #1 [6]	—	1,219		
	Unsited Combustion Turbine [6]	181	—		
2010	West County Unit #1 [6]	1,335	—	25.0%	20.9%
	Changes to Existing QF Purchases [4]	(51)	(47)		
	West County Unit #2 [6]	—	1,219		
	Changes to Non-QF Purchases [5]	(461)	(683)		
2011	West County Unit #2 [6]	1,335	—	28.5%	**19.7%**[8]
	Unsited 2x0 Simple Cycle CT [6]	—	320		
	Changes to Existing QF Purchases [4]	(92)	(45)		
	Changes to Non-QF Purchases [5]	(1)	—		
2012	Supercritical Pulverized Coal Unit # 1 [6] [7]	—	850	27.9%	20.3%
	Unsited 2x0 Simple Cycle CT [6]	362	—		
	Changes to Non-QF Purchases [5]	—	(158)		
2013	Supercritical Pulverized Coal Unit # 1 [6] [7]	855	—	28.6%	21.3%
	Supercritical Pulverized Coal Unit # 2 [6] [7]	—	850		
	Changes to Non-QF Purchases [5]	(180)	—		
2014	Supercritical Pulverized Coal Unit # 2 [6] [7]	855		29.9%	**19.7%**[8] [9]
	Unsited 1x 0 Simple Cycle CT [6]	—	160		
2015	Unsited 1x 0 Simple Cycle CT [6]	181	—	27.3%	**19.7%**[8] [9]
	Unsited 1x 0 Simple Cycle CT [6]	—	160		
	Unsited 2x1 Combined Cycle [6]	—	553		
	TOTALS =	**5,289**	**5,669**		

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of year shown.
(3) Summer values are values for August of year shown.
(4) These are firm capacity and energy contracts with Cogen & Small Power Producers. See Table I.B.1 for more details.
(5) These are firm capacity purchases from Non-QF facilities. See Tables I.D.1 and Table I.D.2 for more details.
(6) All new unit additions are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.
(7) FPL is currently in the process of selecting a site(s) for these advanced technology coal units. FPL expects to announce the selected site(s) by June 2006.
(8) FPL reserve margin values are shown to include what is committed or firmly planned. FPL will continue to pursue the most cost effective alternatives available to meet the then forecasted need with a 20% reserve margin, such as DSM resources that may be added in intervening years or additional purchases.
(9) FPL will continue to pursue development of technologies, such as SCPC or IGCC to meet the needs in these later years.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.5 million people. FPL served an average of 4,318,739 customer accounts in thirty-five counties during 2005. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management, and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, FL. The current generating facilities consist of four nuclear steam units, three coal units, eleven combined cycle units, seventeen fossil steam units, forty eight combustion gas turbines, one simple cycle combustion turbine, and five diesel units. The location of these units is shown on Figure I.A.1 and in Table I.A.1.

FPL's bulk transmission system is comprised of 6,470 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 542 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

I.B Firm Capacity Power Purchases

Purchases From Qualifying Facilities (QF):

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five cogeneration/small power production facilities to purchase firm capacity and energy.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Purchases from Utilities:

Purchased power remains an important part of FPL's resource mix. FPL has a Unit Power Sales (UPS) contract to purchase 931 MW, with a minimum of 381 MW, of coal-fired generation from the Southern Company (Southern) through May, 2010. In January 2005, the Commission approved a new firm purchase contract with Southern that will result in FPL receiving 930 MW from June 2010 through the end of 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 381 MW (Summer) and 390 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. (FPL also has ownership interest in these units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.)

Other Purchases:

FPL has other firm capacity purchase contracts through 2009 with a variety of Non-QF suppliers. These purchases are generally near-term in nature. Table I.B.1 presents the Summer and Table I.B.2 represents the Winter MW resulting from all firm purchased power contracts discussed above through the year 2015.

I.C Non-Firm (As Available) Energy Purchases

FPL purchases non-firm (as-available) energy from several cogeneration and small power production facilities. Table I.C.1 shows the amount of energy purchased in 2005 from these facilities.

Table I.C.1: As Available Energy Purchases From Non-Utility Generators in 2005

Project	***County***	***Fuel***	***In-Service Date***	***Energy (MWH) Delivered to FPL in 2005***
US Sugar-Bryant	Palm Beach	Bagassee	2/80	3,351

Georgia Pacific	Putnam	Paper By-Product	2/94	7,340
Elliot	Palm Beach	Natural Gas	7/05	120

I.D. Demand Side Management (DSM)

FPL's DSM activities continue what has been FPL's practice since 1978 of encouraging cost-effective conservation and load management. FPL's DSM efforts through 2005 have resulted in a cumulative Summer peak reduction of approximately 3,519 MW at the generator and an estimated cumulative energy saving of 33,981 GWH at the generator.

FPL's new DSM Goals for the 2005-2014 timeframe were approved by the Florida Public Service Commission (Commission) on August 9, 2004. FPL's DSM Plan (with which FPL will meet the approved DSM Goals) was approved by the Commission on February 9, 2005 except for the BuildSmart and Residential Conservation Services programs. These two programs received Commission approval on January 10, 2006.

Due to the changes in FPL's resource needs resulting from FPL's updated (November 2005) load forecast previously mentioned in the Executive Summary, FPL is currently planning a number of modifications to its existing DSM programs that will result in additional DSM MW reduction capability above what was projected in the approved DSM

Plan. FPL will seek approval of these program modifications during the second quarter of 2006. To-date, FPL has developed a projection for additional cost-effective DSM that can be implemented in 2006 through 2008. The schedule for new generation additions presented in this document are based on the implementation of these additional DSM MW through 2008. FPL will continue to analyze the potential for additional cost–effective DSM for 2009–on in its ongoing resource planning work in 2006.

1/ These ratings are peak capability.
2/ These ratings represent Florida Power & Light Company's share of Scherer Unit No. 4, adjusted for transmission losses.
3/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Unit No. 1 and No. 2, excluding Jacksonville Electric Authority (JEA) share of 80%.
4/ Total capability is 853/839 MW. Capabilities shown represnet FPL's share of the unit and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 15%.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are developed on an annual basis for resource planning work at FPL. These forecasts are a key input to the models used to develop the Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

The primary drivers to develop these forecasts are demographic trends, weather, economic conditions, and prices of electricity. In addition, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from the National Oceanic and Atmospheric Administration (NOAA), and inputs from FPL's own customer service planning areas. In the area of demographics, population trends by county, plus housing characteristics such as housing starts, housing size, and vintage of homes are assessed.

Forecasts for electric usage in the residential and commercial classes include end-use information such as appliance saturation studies, efficiencies, and intensity of energy use. In addition to these inputs, residential forecasts also make use of household characteristics such as ages of members in households, number of members in households, and income distributions.

The projections for the national and Florida economy are obtained from Global Insight. Population projections for the counties served by FPL are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. In addition, FPL actively participates with local development councils and universities to obtain their assessments of the local economy, specifically in the area of expansion of new businesses and retention of the current business base. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects the company's sales and peak demand. Weather variables are used in the forecasting models for energy sales and peak demand. There are two sets of weather variables developed and used in forecasting models:

1. Cooling and Heating Degree-Days are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. A composite temperature hourly profile is derived using hourly temperatures across FPL's service territory (Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained) weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Days which are based on starting point temperatures of 72°F and 66°F, respectively. Similarly, composite temperature and hourly profile of temperature are used for the Summer and Winter peak models.

II.A. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class for the forecasting period of 2005-2024 and are adjusted to match the Net Energy for Load (NEL) forecast. The results of these sales forecasts for the years 2006-2015 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and Net Energy for Load forecast are outlined below.

1. Residential Sales

Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, real Florida personal income, Cooling and Heating Degree-Days as explanatory variables. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. To capture economic conditions, the model includes Florida's real personal income. The degree of economic prosperity can, and does, affect residential electricity sales. The impact of weather is captured by the Heating Degree-Days and, two weighted variables for cooling degree days accounting for cooling degree days from the previous month are also included as an explanatory variable. The degree of economic prosperity can, and does, affect residential electricity sales. Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted. The long-term annual model is similar except that Florida real per capita in included as an economic explanatory variable rather than Florida total personal income. Also the annual model includes annual cooling degree days.

2. Commercial Sales

The commercial sales forecast is also developed using a regression model. Commercial sales are a function of the following variables: Florida's real personal income, commercial real price of electricity, two variables for Cooling Degree-Days weighted for previous month and current month, and an autoregressive term. The long-term model is similar, except annual cooling degree days is used as explanatory weather variable as opposed to weighted monthly cooling degree days. In addition the long term model does not include an autoregressive term. Florida's real personal income is used to capture the economic activity in FPL's service territory. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree-Days are used to capture weather-sensitive load in the commercial sector.

3. Industrial Sales

The industrial sales forecast is also developed using a regression model. Industrial sales are a function of lagged industrial sales, the real price of electricity, Cooling Degree-Days, a dummy variable for outliers, and an autoregressive term. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. The Cooling Degree-Day term is included to capture the weather-sensitive load in the industrial class. The Long term model consists of real price of electricity and Florida's manufacturing employment.

4. Other Public Authority Sales

At present, this class consists of sports fields and one government account. The forecast for this class is based on historical knowledge of its characteristics.

5. Street & Highway Sales and Railroad & Railways Sales

The forecast for street and highway sales is developed by first assuming a constant use per customer and then multiplying that value by the number of projected customers. The forecast of sales to railroad & railways is based on historical knowledge of its characteristics. This class consists of Miami-Dade County's Metrorail system.

6. Sales for Resale

Sales for resale (wholesale) customers are composed of municipalities and/or electric cooperatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Currently, there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of Key West, Florida (City of Key West), Miami-Dade County, and the Florida Municipal Power Agency (FMPA). Sales to the Florida Keys are forecasted using a regression model. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor. Miami-Dade County sells 60 MW to Progress Energy. Line losses are billed to Miami-Dade under a wholesale contract. FMPA has contracted for delivery of 75 MW from FPL through October, 2007.

7. Total Sales

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual Net Energy for Load (NEL).

II.B. Net Energy for Load

An annual econometric model is developed to produce a net energy for load (NEL) forecast. The key inputs to the model are: the real price of electricity, Heating and Cooling Degree-Days, Florida Non-Agricultural Employment, and an autoregressive term. The monthly model is similar, except the economic variables utilized are Florida's real personal income and a dummy variable for February. The first year of the forecast is developed from a daily model which consists of similar explanatory variables as monthly model except includes variables for weekends and holiday. The forecasts thereafter for the following four years are obtained from the short-term monthly model. Forecasts for subsequent years are generated using the growth rates from the annual model.

Once an annual NEL forecast is obtained using the above-mentioned methodology, the results are then compared for reasonableness to the NEL forecast generated using the total sales forecast. The sales by class forecasts previously discussed are then adjusted to match the NEL from the annual NEL model.

The forecasted NEL values for 2006 – 2015 are presented in Schedule 3.3 that appears at the end of this chapter.

II.C. System Peak Forecasts

The rate of absolute growth in FPL system load has been a function of a growing customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the peak forecast models to capture these behavioral relationships.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2006–2015 are presented in Schedules 3.1 and 3.2 as well as in Schedules 7.1 and 7.2.

System Summer Peak

The Summer peak forecast is developed using an econometric model. The variables included in the model are the price of electricity, Florida real personal income, average temperature and a heat buildup weather variable consisting of the sum of the cooling degree hours during the peak day and three prior days. The model below is based on Summer peak load per customer. The Summer peak load per customer value is multiplied by total customers to derive FPL's system Summer peak.

System Winter Peak

Like the system Summer peak model, this model is also an econometric model. The model consists of two weather-related variables: the square of the minimum temperature on the peak day, heating degree hours for the prior day as well as for the morning of the winter peak day. In addition, Florida real personal income is a variable used in the model. The model below is based on Winter peak load per customer. The Winter peak load per customer value is multiplied by total customers to derive FPL's system Winter peak.

Monthly Peak Forecasts

Monthly peaks for the 2005-2024 period are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peaks (Summer = April-October, Winter = November-March.)

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.D. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2005-2024 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. These daily load shapes are ranked and used with forecasted monthly peaks, NEL, and calendars in developing an hourly forecast. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

Historical Values (1996 - 2005):

Col. (2) - Col. (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 1996 through 2005 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial /Industrial Demand Reduction (CDR). Col.(5) - Col.(9) for year 2004 are "estimated actuals" and are August values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8).

Projected Values (2006 - 2015):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col. (9) represent all incremental conservation and cumulative load control. These values are projected August values and the conservation values are based on projections with a 1/2004 starting point for use with the 2004 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.2
History and Forecast of Winter Peak Demand:Base Case

(1) Year	(2) Total	(3) Firm Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management	(7) Residential Conservation	(8) C/I Load Management	(9) C/I Conservation	(10) Net Firm Demand
1996/97	16,490	626	15,864	0	578	311	417	139	15,495

2002/03	20,190	246	19,944	0	847	546	453	206	18,890
2003/04	14,752	211	14,541	0	857	570	532	230	13,363
2004/05	18,108	225	17,883	0	862	583	542	233	16,704
2005/06	19,683	225	19,458	0	870	600	550	240	17,424
2006/07	22,294	228	22,066	0	964	58	605	20	20,647
2007/08	22,753	231	22,522	0	1,001	85	631	28	21,007
2008/09	23,245	161	23,084	0	1,042	113	656	38	21,395
2009/10	23,714	166	23,548	0	1,062	139	663	42	21,807
2010/11	24,155	171	23,984	0	1,084	167	669	47	22,188
2011/12	24,597	171	24,426	0	1,107	194	676	52	22,568
2012/13	25,061	171	24,890	0	1,133	222	683	57	22,967
2013/14	25,561	171	25,390	0	1,160	249	690	62	23,400
2014/15	26,244	171	26,073	0	1,189	275	696	67	24,017

Historical Values (1996/97 - 2005/06):

Col. (2) - Col. (4) are actual values for historical winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col.(9) for 1996/97 through 2005/06 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial/Industrial Demand Reduction (CDR).Col.(5) - Col.(9) for year 2004/05 are "estimated actuals" and are January values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col. (2) - Col. (6) - Col. (8).

Projected Values (2006/07- 2014/15):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col.(9) represent all incremental conservation and cumulative load control. These values are projected January values and the conservation values are based on projections with a 1/2004 starting point for use with the 2004 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.3
History and Forecast of Annual Net Energy for Load - GWH: Base Case

(1) Year	(2) Total	(3) Residential Conservation	(4) C/I Conservation	(5) Retail	(6) Sales for Resale GWH	(7) Utility Use & Losses	(8) Net Energy For Load	(9) Load Factor(%)
1996	87,007	971	1,043	85,654	1,353	6,306	84,993	60.2%
1997	89,243	1,213	1,177	88,015	1,228	5,771	86,853	59.7%
1998	95,318	1,374	1,282	93,992	1,326	6,206	92,662	59.1%
1999	94,365	1,542	1,365	93,412	953	5,829	91,458	59.3%
2000	99,097	1,674	1,434	98,127	970	7,059	95,989	61.4%
2001	101,739	1,789	1,545	100,768	970	7,222	98,404	59.9%
2002	107,755	1,917	1,639	106,522	1,233	7,443	104,199	61.9%
2003	112,160	2,008	1,759	110,648	1,511	7,386	108,393	62.9%
2004	112,031	2,106	1,834	110,500	1,531	7,464	108,091	59.9%
2005	115,440	2,205	1,934	113,933	1,506	7,498	111,301	58.9%
2006	114,965	148	84	113,420	1,545	8,104	114,733	59.9%
2007	118,820	234	153	117,298	1,522	8,339	118,433	60.2%
2008	123,720	325	192	122,654	1,066	8,736	123,203	60.8%
2009	128,211	423	217	127,129	1,082	9,013	127,571	61.5%
2010	132,519	526	228	131,421	1,098	9,310	131,765	62.1%
2011	135,540	632	238	134,443	1,098	9,522	134,670	62.1%
2012	138,666	742	249	137,569	1,098	9,742	137,675	62.0%
2013	141,993	856	260	140,896	1,098	9,976	140,877	62.2%
2014	145,244	972	272	144,146	1,098	10,204	144,000	62.2%
2015	148,456	1,021	278	147,368	1,098	10,430	147,167	62.2%

Historical Values (1996 - 2005):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: Col. (2) = Col. (3) + Col. (4) + Col. (8).

Col.(3) & Col.(4) for 1996 through 2005 are DSM values starting in January 1988 and are annual (12-month) values.Col. (3) and Col. (4) for 2004 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWH reductions actually experienced each year .

Col. (5) & Col. (6) are a breakdown of Net Energy For Load in Col (2) into Retail and Wholesale .

Col. (9) is calculated using Col. (8) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (8)*1000) / ((Col.(2) * 8760)

Projected Values (2006 - 2015):

Col. (2) represents Net Energy for Load w/o DSM values. The values are extracted from Schedule 2.3, Col. (19).

Col. (3) & Col. (4) are forecasted values of the reduction on sales from incremental conservation and are mid-year (6-month) values. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) & Col. (6) are a breakdown of Net Energy For Load in Col (2) , into Retail and Wholesale.

Col. (8) NEL projected values shown here do include the impact of conservation in Col. (3) and Col. (4). Therefore, these NEL values do not match those shown on schedule 2.3 because those values do not account for incremental conservation.

Col. (9) is calculated using Col. (2) from this page and Col. (2), "Total", from Schedule 3.1. Col. (9) = ((Col. (2)*1000) / ((Col. (2) * 8760)
Adjustments are made for leap years.

Schedule 4
Previous Year Actual and Two-Year Forecast of
Retail Peak Demand and Net Energy for Load (NEL) by Month

(1)	(2)	(3)	(4)	(5)	(6)	(7)

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990's and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of potential new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2005 and early 2006 resource planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Determine the economics for the total utility system with each of the competing options and resource plans; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

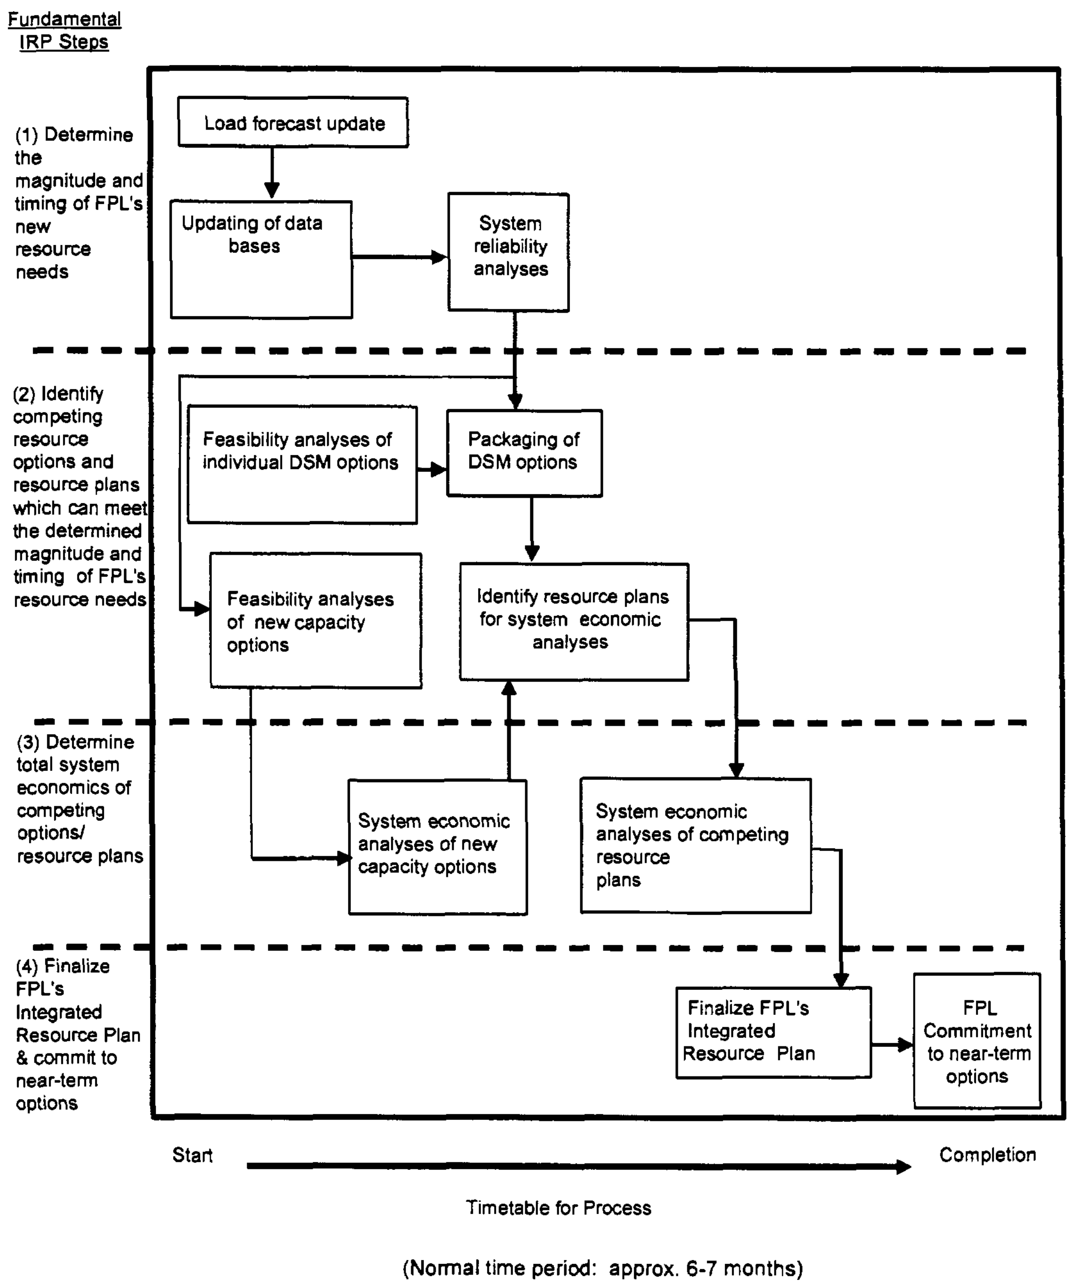

Figure III.A.1: Overview of FPL's IRP Process

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps, determining the magnitude and timing of FPL's resource needs, is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a resource adequacy or reliability assessment for the utility system.

Step 1 typically starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information that is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) short-term, firm capacity purchase additions, and (3) short-term and long-term DSM implementation.

The first of these assumptions is based on FPL's ongoing engineering and construction activities to add near-term capacity. These construction activities involve a new CC unit at FPL's Turkey Point site scheduled to come in-service by mid-2007. FPL selected this capacity option after conducting an RFP during 2003. The addition was approved by the FPSC in June of 2004 and the Governor and Siting Board approved certification of the plant location, construction, and operation of the new CC unit in February, 2005.

The second of these assumptions involves short-term, firm capacity purchase additions. These firm capacity purchases are from a combination of utility and independent power producers. Several new near-term firm capacity purchases are now projected in this year's Site Plan. Details, including the annual total capacity values for these purchases are presented in Tables I.B.1 and I.B.2. These purchased capacity amounts were incorporated in FPL's recent resource planning work.

The third of these assumptions involves DSM. Since 1994, FPL's resource planning work has assumed that the DSM MW called for in FPL's approved DSM Goals is achieved per plan in its analyses. This was again the case in FPL's most recent planning work, as its new DSM Goals that address the years 2005 through 2014, and that were approved by the FPSC in August 2004, are assumed to be achieved per plan.

FPL realized significant load growth in 2005. When this growth was reviewed it was determined that population growth beyond that forecast was responsible for the change. As a result, the load forecast was updated in November 2005. At that time, the amount and timing of cost-effective DSM was reviewed resulting in the identification of an additional 309 MW of Summer demand reduction capability. This additional DSM capability can be implemented with additional program signups through 2008, plus modifications to existing programs. These additional MW of DSM were also accounted for prior to making projections of new construction additions that are discussed in this document.

These key assumptions, plus the other updated information, are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its native load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the generation resource adequacy of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss–of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program currently used by FPL.

The result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. Following the significantly higher loads experienced during the summer of 2005, FPL's peak load forecast was revised upwards in November 2005 as discussed in Chapter II. Consequently, FPL's projected capacity needs have both accelerated and increased in magnitude. Information regarding the timing and magnitude of these resource needs is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analysis of new capacity options are conducted to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs.

The individual new capacity options are then "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using dynamic programming techniques.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs were identified. These resource plans were then compared on an economic basis to determine FPL's most cost-effective self build alternative.

In 2005, FPL issued a Request for Proposals (RFP) seeking proposals for firm capacity additions in 2009–2011. FPL received five such proposals in response to this solicitation (one proposal was subsequently withdrawn by its bidder). These options were also analyzed in FPL's resource planning work as alternatives to FPL's most cost-effective self build alternative.

Step 3: Determining the Total System Economics:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for comparing the system economics of these resource plans. In its 2005 resource planning work, FPL performed much of this work of combining resource options into resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI). The EGEAS model was also used to perform much of the basic economic analyses of the resource plans. For various analyses, including the analyses of proposals received in response to FPL's RFP, FPL also applied the P-MArea production cost model to develop a more detailed perspective of the production costs for the various resource plans developed in the EGEAS model. The P-MArea model is the model used by FPL to develop the Fuel Cost Budget and to conduct other production cost-related analyses including the detailed economic analysis of RFP proposals.

In 2005, FPL also utilized several other models in its resource planning work. For DSM analyses, FPL used its DSM cost-effectiveness model; an FPL spreadsheet model utilizing the FPSC's approved methodology for analyzing the cost-effectiveness of individual DSM measures/programs, and its non-linear programming model for analyzing the potential for lowering system peak loads through additional load management capacity.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases such as existed for much of FPL's most recent planning work in which the DSM contribution was assumed as a given and the only competing options were new generating units and purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans were evaluated on a cumulative present value system revenue requirement basis that includes the system capital and operating costs of the new capacity options and existing FPL units.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps were used to develop the future generation plan. This plan is presented in the following section.

III.B Incremental Resource Additions

FPL's projected incremental generation capacity additions/changes for 2006 through 2015 are depicted in Table III.B.1 (the planned DSM additions are shown separately in Tables III.D.1 and III.D.2). These capacity additions/changes result from a variety of actions including: changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, implementation of additional cost-effective DSM, and by projected construction of new generating units.

As shown in Table III.B.1, the capacity additions are largely made up of committed new construction, new purchases, and proposed self-build alternatives. (The additional DSM MW are not presented in this table but have been accounted for prior to making these new capacity option projections.) The new construction contribution includes the addition of a new CC unit in 2007 at FPL's Turkey Point site and the planned addition of new CC units in 2009 and 2010 at the West County Energy Center site. FPL is also projecting additional firm capacity power purchase contributions for the 2006 through 2009 time period. These purchases, combined with the Turkey Point and West County Energy Center construction projects (plus the additional cost-effective DSM MW), address FPL's resource needs for 2006 through 2010 with the exception of 2008. The 2008 need is partially addressed by these resource additions.

FPL anticipates addressing its remaining 2008 need with additional purchases/leases, enhancements to its existing units, and/or the construction of one CT. For purposes of this planning document, FPL projects the construction of one unsited CT.

FPL's resource need for 2011 will be addressed with additional cost-effective DSM, power purchases, capacity increases to FPL's existing units, or by construction of new CTs. For purposes of this planning document, FPL projects the construction of two unsited CT's.

FPL projects the construction of two new advanced technology coal units; one each in 2012 and 2013. These two units will use supercritical pulverized combustion technology in concert with an advanced emissions control suite to meet FPL's resource needs for 2012 and 2013 and greatly enhance FPL's fuel diversity. The amount of capacity needed and the technologies that would ultimately be chosen to meet the need for these years will be based on FPL's ongoing review of technology, environmental requirements, regulation and economic factors and will not be restricted to a single technology.

For addressing its 2014 and 2015 resource needs in this planning document, FPL projects the construction of one unsited CT in 2014, one unsited CT in 2015, and one unsited 2x1 CC any of which could be converted to coal gasification once the technology is able to meet reliability and cost-effectiveness standards.

Table III.B.1: Projected Capacity Changes for FPL [1]

Projected Capacity Changes and Reserve Margins for FPL [1]

		Net Capacity Changes (MW)	
		Winter [2]	Summer [3] [8]
2006	Changes to Existing QF Purchases [4]	(132)	(136)
	Changes to existing Units	205	142
	Changes to Non-QF Purchases [5]	147	440
2007	Turkey Point Combined Cycle #5 [6]	---	1,144
	Changes to existing Units	70	77
	Changes to Non-QF Purchases [5]	73	(412)
2008	Changes to existing Units	4	12
	Turkey Point Unit #5 [6]	1,181	---

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of year shown.
(3) Summer values are values for August of year shown.
(4) These are firm capacity and energy contracts with Cogen & Small Power Producers. See Table I.B.1 for more details.
(5) These are firm capacity purchases from Non-QF facilities. See Tables I.D.1 and Table I.D.2 for more details.
(6) All new unit additions are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.
(7) FPL is currently in the process of selecting a site(s) for these advanced technology coal units. FPL expects to announce the selected site(s) by June 2006.
(8) FPL reserve margin values are shown to include what is committed or firmly planned. FPL will continue to pursue the most cost effective alternatives available to meet the then forecasted need with a 20% reserve margin, such as DSM resources that may be added in intervening years or additional purchases.
(9) FPL will continue to pursue development of technologies, such as SCPC or IGCC to meet the needs in these later years.

III.C Issues Impacting FPL's Recent Planning Work

FPL's 2005 and early 2006 planning efforts have continued to address two issues that were identified in previous Site Plans as being items of on-going importance. Those two issues are: (1) the need to address the imbalance between regional load and generating capacity located in southeast Florida, and (2) the desire to maintain and enhance a balanced fuel supply in the FPL system.

1. Southeast Imbalance

There currently is an imbalance between regionally installed generation and peak load in southeast Florida. A significant amount of energy required in the southeast Florida region during peak periods is provided through the transmission system from plants located outside the region. Based on the forecast for continued load growth in this region, the imbalance between generation and load is projected to increase unless additional generation capacity is periodically located within this region.

FPL's prior planning work concluded that either additional installed capacity in this region or transmission capacity capable of delivering additional electricity from outside the region would be required to address this imbalance. Delivering additional electricity from outside the region incurs both increased transmission-related costs (system integration equipment, losses, and impact to operating costs) and the costs of additional capacity that would be built outside of the region. The evaluation conducted as part of FPL's Request for Proposals (RFP) process determines the most cost-effective means to meet FPL's needs by considering all cost components of FPL's next planned generating unit (NPGU) and alternative options, including transmission-related costs. The locations of the NPGU, and the locations of proposed units included in the alternative option combinations, contribute to the transmission-related costs determined in the evaluation. The results of the RFP evaluations confirm that because of the existing imbalance, generating units located in the southeast Florida region contribute significantly lower transmission-related costs than do those located outside the region.

Partly because of the lower transmission-related costs resulting from their location, Turkey Point Unit #5 and West County Units #1 and #2 were evaluated as the most cost-effective options to meet FPL's 2007 and 2009-2010 capacity needs, respectively. Adding Turkey Point Unit #5 will significantly reduce the imbalance between generation and load in southeast Florida. However, assuming no other resources are added, the imbalance is projected to re-develop within several years because of the continued load growth of approximately 250-300 MW per year in this region. Therefore, the southeast Florida imbalance is a recurring factor in the calculation of transmission-related costs which are an integral part of the evaluation of new capacity additions. This was again the case in FPL's 2005 RFP, which resulted in the identification of West County Units #1 and #2 as the most cost effective alternatives to meet the need of a growing system. The RFP analysis showed that the West County units offered significantly lower transmission related costs in comparison to other proposals evaluated. Based on the current load forecast and system resources the combined effect of the Turkey Point Unit #5 and the West County Units #1 and #2 unit additions (assuming an affirmative Determination of Need is granted for West County Units #1 and #2) would substantially mitigate the imbalance issue until near the end of the ten year planning horizon addressed in this Site Plan.

2. Balanced Fuel Supply.

FPL also has taken positive steps in 2005 to address the issue of fuel diversity in the FPL system on a number of fronts. Once a resource need is established, and after accounting for all reasonably available, cost-effective DSM alternatives, FPL recognizes that there are many resource options that can contribute to fuel diversity. The following discusses the key activities FPL has undertaken to develop resources that are not reliant on oil or natural gas as the primary fuels.

In March 2005, FPL presented its analysis of the benefits and risks of adding advanced technology coal generation to the FPL System. The *Report on Clean Coal Generation* (Coal Study) was presented to the FPSC summarizing FPL's findings. Based on the assumptions at the time these findings showed that, while there are uncertainties surrounding the costs of coal-fueled generation, significant cost and fuel reliability benefits may be obtained by adding advanced technology coal generation. During 2005, FPL and its customers were subjected to a volatile natural gas and oil commodity market. The long-term future price expectation for these fuels has risen, increasing the value offered by advanced technology coal generation above that documented in the Coal Study. Understandably, FPL maintains its pursuit of two new supercritical pulverized coal units with advanced emission control technology, one each in 2012 and 2013.

In September 2005, FPL issued a two-part RFP. Part I solicited proposals to address FPL's 2009-2011 capacity needs and this solicitation was open to all fuel-types and technologies. These proposals were received on November 9, 2005. Only natural gas-fired generation or utility system-based capacity was offered in response to Part I of the RFP. Part II of the RFP identified that FPL plans to request proposals in 2006 limited to fuel diverse generation alternatives for its 2012-2014 capacity needs. FPL held a meeting in December 2005 with interested parties to identify issues of concern and encourage market interest in the process. As part of its development efforts in 2005, FPL attempted but was unsuccessful in its petition for a zoning variance in St. Lucie County to accommodate a selected site for an advanced technology coal plant. Because of the significant economic and reliability benefits offered by advanced technology coal generation, FPL continues to actively pursue other sites for advanced technology coal plant and will make every effort to bring two units into service in 2012 and 2013, respectively.

During early 2005, FPL completed an RFP for Liquified Natural Gas (LNG) supply by concluding that no proposal offered economic benefits that warranted entering into a long-term supply arrangement necessary to support such a facility. FPL's view remains that LNG can be an effective means to add fuel supply diversity to FPL, and the company will continue to investigate the feasibility of such projects in the coming years.

FPL has maintained an interest in pursuing Integrated Gasification Combined Cycle (IGCC) technology. In the past year, FPL has worked with the industry's leading IGCC developers to explore creative means that might bring this technology to FPL's customers. This effort is focused on resolving reliability and cost uncertainty and demonstrating that addition of the technology will benefit our customers. FPL's planned capacity for 2014 and 2015 in this Site Plan are such that they could support an IGCC technology alternative, should these areas of uncertainty be resolved by 2008.

During 2005 and early 2006, 9 major US utilities have announced an intent to pursue new nuclear generation facilities. FPL has begun the process to review the prospect for new nuclear generation and the advisability of initiating significant financial commitments in the face of schedule, cost and regulator uncertainties. FPL believes that being an active participant in this process is necessary in order to preserve new nuclear generation as a viable alternative in maintaining a balanced fuel supply. Therefore, FPL will be taking the necessary steps in the near future to preserve new nuclear generation as an option for enhancing fuel diversity in the FPL system.

FPL also has been involved in activities in 2005 to investigate adding or maintaining renewable resources as a part of its generation supply. These activities include discussions with existing facilities aimed at maintaining or extending current agreements. Additionally, FPL is actively investigating a site for a demonstration wind generation project on the East coast of Florida. The project is estimated to be in the 10 MW range and may be on-line as early as 2007. FPL maintains its interest in new and developing technologies, such as solar photovoltaic and ocean current turbine technology. FPL supports pilot projects in solar photovoltaic technology throughout its system helping to provide platforms to refine the technology and reduce its cost. The common outlook for renewable technologies is that they may become more cost-effective over the next ten years and may be feasible additions to provide some diversity to the system fuel supply. FPL shares, with others, the objective of fostering the development and operation of additional cost-effective renewable sources of generation. Based upon available information, however, FPL does not believe that renewable resources are likely to contribute more than a modest amount to satisfying the annual electric load growth in FPL's territory.

In the future, FPL will continue to identify and evaluate alternatives that may maintain or enhance fuel diversity in its capacity resource mix including purchasing power from coal-fired facilities when such power becomes available. FPL also plans to maintain the ability to utilize fuel oil at those existing units that have that capability, although price factors currently limit the expected use of these facilities.

III.D Demand Side Management (DSM)

1. Currently Approved Programs and Goals:

FPL's currently approved DSM programs are summarized as follows:

Residential Conservation Service: This is an energy audit program designed to assist residential customers in understanding how to make their homes more energy-efficient through the installation of conservation measures/practices.

Residential Building Envelope: This program encourages the installation of energy-efficient ceiling insulation and reflective roofs in residential dwellings that utilize whole-house electric air conditioning.

Duct System Testing and Repair: This program encourages demand and energy conservation through the identification of air leaks in whole-house air conditioning duct systems and by the repair of these leaks by qualified contractors.

Residential Air Conditioning: This is a program to encourage customers to purchase higher efficiency central cooling and heating equipment.

Residential Load Management (On-Call): This program offers load control of major appliances/household equipment to residential customers, in exchange for monthly electric bill credits.

New Construction (BuildSmart): This program encourages the design and construction of energy-efficient homes that cost-effectively reduce coincident peak demand and energy consumption.

Residential Low Income Weatherization: This program addresses the needs of low-income housing retrofits by providing monetary incentives to various housing authorities, including weatherization agency providers (WAPS), and non-weatherization agency providers (non-WAPS). These incentives are used by the housing authorities to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting.

Business Energy Evaluation: This program encourages energy efficiency in both new and existing commercial/industrial facilities by identifying DSM opportunities and providing recommendations to the customer.

Commercial/Industrial Heating, Ventilating, and Air Conditioning: This program encourages the use of high-efficiency heating, ventilation, and air conditioning (HVAC) systems in commercial/industrial facilities.

Commercial/Industrial Efficient Lighting: This program encourages the installation of energy-efficient lighting measures in commercial/industrial facilities.

Business Custom Incentive: This program encourages commercial/industrial customers to implement unique energy conservation measures or projects not covered by other FPL programs.

Commercial/Industrial Load Control: This program reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages, in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

Commercial/Industrial Demand Reduction: This program, which started in 2002, is similar to the Commercial/Industrial Load Control program mentioned above in continuing the objective to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits.

Commercial/Industrial Building Envelope: This program encourages the installation of energy-efficient building envelope measures, such as roof/ceiling insulation and reflective roof coatings for commercial/industrial facilities.

Business On Call: This program offers load control of central air conditioning units to both small non–demand-billed and medium demand-billed commercial/industrial customers in exchange for monthly electric bill credits.

FPL's approved DSM Goals for summer MW reduction from these programs are presented in Table III.D.1.

Year	Goal Cumulative Summer MW
2005	74
2006	142
2007	212
2008	287
2009	366
2010	448
2011	532
2012	619
2013	708
2014	802

Table III.D.1: FPL's Summer MW Reduction Goals for DSM (At the Meter)

Table III.D.1 reflects FPL's DSM Goals for 2005–2014 as approved by the Florida Public Service Commission in June, 2004. These annual cumulative values assume a 1/1/05 starting point.

2. Research and Development

FPL continues to support research and development activities. Historically, FPL has performed extensive DSM research and development. FPL will continue such activities, not only through its Conservation Research and Development program, but also through individual research projects. These efforts will examine a wide variety of technologies that build on prior FPL research where applicable and will expand the research to new and promising technologies as they emerge.

Conservation Research and Development Program

FPL's Conservation Research and Development Program is designed to evaluate emerging conservation technologies to determine which are worthy of pursuing for program development and approval. FPL has researched a wide variety of technologies such as condenser coil cleaner and coating, ultraviolet lights for evaporator coils, Energy Recovery Ventilators (ERV), fuel cell demonstrations, CO_2 ventilation control, two-speed air handlers, and duct plenum repair. Many of the technologies examined have resulted in enhancements to existing programs or the development of new programs such as

Residential New Construction, Commercial/Industrial Building Envelope, and Business On Call.

Green Power Pricing Research Project

Under this project, FPL is examining the feasibility of purchasing tradable renewable energy credits generated from new renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable sources. Residential customers who participate are charged higher premiums for purchasing the tradable renewable energy credits associated with electric energy generated by these sources.

Development of the Green Pricing program was completed and filed with the FPSC in August 2003. As part of this process, a supply contract was put into place that allows FPL to match supply with demand for green energy. Tradable renewable energy credits are used to supply the renewable benefits required of this project. The FPSC approved the program on December 2, 2003 with program implementation the first quarter of 2004. As of year-end 2005, FPL had over 23,000 project participants.

On Call Incentive Reduction Pilot

In March 2003, FPL received FPSC approval to perform a pilot for its On Call Program. Under the pilot FPL is offering to new participants a residential load control service similar to the On Call Program at a reduced incentive level. The offering of this pilot is allowing FPL to test its market research data and gauge whether FPL can repackage its current residential load control service, minimize customer attrition, achieve current goals for residential load control, and, ultimately, change On Call incentive levels without damaging FPL system reliability.

Business Green Energy Research Project

As mentioned above, FPL currently has a R&D project addressing residential customer acceptance of green energy. In an attempt to determine business customer acceptance of green pricing rates, FPL is investigating if it is feasible to design and implement a Green Energy Program that addresses these customer segments.

3. Additional DSM Contributions

FPL's updated load forecast previously discussed in Chapter II, and the corresponding acceleration and growth in FPL's projected resource needs previously discussed in this chapter, will enable FPL to cost-effectively implement additional DSM above what is projected in FPL's approved DSM Plan. FPL will petition the FPSC starting in the second quarter of 2006 for approval of modifications to a number of its existing DSM programs that will enable FPL to achieve additional cost-effective DSM MW. The projected additional peak load reduction impacts of these DSM program modifications, which includes both new program measures and increased program signups, is presented in Table III.D.2

Year	Additional Summer MW @ Generator
2006	39
2007	229
2008	289
2009	309

Table III.D.2: FPL's Additional Summer MW of DSM

FPL's analyses of these additional DSM contributions has focused to-date on addressing FPL's near-term (2006–2008) capacity needs. Program implementation that occurs between the summer of 2008 and the end of 2008 are shown as a "carryover" impact to the summer of 2009. On-going analyses will continue to examine the potential for additional cost-effective DSM contributions for subsequent years 2009-on.

III.E Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents certain of FPL's proposed future additions of 230 kV and 500 kV bulk transmission lines including those corresponding to proposed generating facilities and those that must be certified under the Transmission Line Siting Act.

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (kV)	(7) Capacity (MVA)
FPL	Collier (1)	Orange River #3	54	Dec-06	230	759
FPL	St. Johns	Pringle	26	Dec-08	230	759
FPL	Manatee	BobWhite	30	Dec-11	230	1190
FPL	Eve	Sweatt	25	Jun-12	230	759

(1) Final order certifying the corridor was issued on July 19 of 2004.

Table III.E.1: List of Proposed Power Lines

In addition, there will be transmission facilities needed to connect several of FPL's committed and projected capacity additions to the system transmission grid. These transmission facilities for the committed capacity additions at FPL's existing Turkey Point plant and for the projected capacity additions at the West County Energy Center site areas are described below.

Since the projected capacity additions for 2008, and for 2011 through 2015, are as-yet unsited, or their transmission facility needs can only be determined after sites for earlier units are determined, no transmission facilities information is provided for these units. This information will be provided in the 2006 Site Plan Addendum for the 2012 and 2013 advanced technology coal projects when sites have been selected.

III.E.1 Transmission Facilities for Turkey Point Unit #5

The work required to connect the new capacity addition at Turkey Point in 2007 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's and one steam turbine.
2. Construct two string busses to connect the collector busses and main switchyard.
3. Add five main step-up transformers (4-225MVA, 1-560 MVA), one for each CT and one for the steam turbine.
4. Add a new two breaker bay to connect the collector bus at the Turkey Point switchyard.
5. Add a second two breaker bay at the Turkey Point switchyard to connect the other collector bus.
6. Add relays and other protective equipment.
7. Expand site and relay vault for two new line terminals at Turkey Point switchyard.

II. Transmission:

1. Upgrade the Turkey Point-Galloway Tap 230kV transmission line section to 1418 Amps.
2. Upgrade the Turkey Point–McGregor-Florida City 230kV transmission line section to 1403 Amps.
3. Upgrade the Turkey Point-Miller 230kV transmission line section to 1356 Amps.
4. Upgrade the Miller-Killian 230kV transmission line section to 1315 Amps.

III.E.2 Transmission Facilities for West County Unit #1

The work required to connect West County Energy Center Unit #1 projected to be added in 2009 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's and one steam turbine.
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 230 kV Substation.
3. Add five main step-up transformers (4-225 MVA, 1-560 MVA), one for each CT and one for the steam turbine.
4. Add a new Bay #4 with 3 breakers at the Corbett 230 kV main switchyard. Connect one string buss from the collector yard and relocate the Alva 230 kV terminal from Bay #3 to new Bay #4.
5. Connect second collector string buss to Bay #3.
6. Add relays and other protective equipment.

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.E.3 Transmission Facilities for West County Unit #2

The work required to connect West County Energy Center Unit #2 projected to be added in 2010 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 4 breakers to connect the three CT's, and one ST.
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 500kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA) one for each CT, and one for the ST.
4. At Corbett Sub, install one breaker and relocate Martin #2 500 kV line from Bay 2S to Bay 2N. Install one West County 500 kv string bus into Bay 2S.
5. At Corbett Sub, install one breaker and second West County 500 kV string bus into Bay 1S.
6. Add relays and other protective equipment.

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various technologies.

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970's in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities on both a daily and annual basis in Florida. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-Kilowatt (KW) system was placed into operation in 1984. (The system was removed in 1990 to make room for substation expansion after the testing of this PV installation was completed.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed on the following page).

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first and only utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was not cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980's, FPL introduced another renewable energy program. FPL's Passive Home Program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for 6 passive homes with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test may be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

More recently, FPL has analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach does not require all of its customers to bear PV's high cost, but allows customers who are interested in facilitating the use of renewable energy the means to do so. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund that FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid. Thus, when sunlight is available, the PV-generated electricity displaces an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach, which has been termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL began the effort in 1998 and received approximately $89,000 in contributions (that significantly exceeded the goal of $70,000). FPL purchased the PV modules and installed them at FPL's Martin Plant site.

FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was the Green Energy Project. The objectives of this Project were to: determine customer interest in an on–going renewable energy program, determine their price responsiveness and views on the different renewable technologies, and identify potential renewable energy supply sources that would meet the forecasted customer demand for this type of product. FPL both conducted customer research and issued a Request for Proposals (RFP) in 2001 to solicit proposals to potentially supply energy only (MWH) from new renewable sources. This Project formed the basis for FPL's existing Green Power Pricing Research Project, and then led to FPL's Business Green Energy Research Project, that are discussed in Section III.D.2.

The second effort initiated in 2000 was FPL's Photovoltaic Research, Development, and Education Project. This demonstration project's objectives were to: increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks (as well as the total annual energy capabilities of roof tile PV systems), and assess the homeowner's financial benefits and costs of PV roof tile systems. This project was completed in 2003.

FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy and as-available energy have been purchased by FPL from these developers. (Please refer to Tables I.B.1,I.B.2, and Table I.C.1).

Additionally, FPL is actively investigating a site for a demonstration wind generation project on the East Coast of Florida. The project is estimated to be in the 10 MW range and may be on-line as early as 2007. FPL also maintains an interest in other developing renewable technologies such as ocean current turbine technology.

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980's, FPL relied primarily on a combination of oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil–fired generation. In the early 1980's FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the

partial acquisition (76%) of Scherer Unit #4 in 1989. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP.

The trend in recent years has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective combined cycle generating units. This planning document shows a slowing of that trend as FPL's plans have realized the benefits of efficient gas-fired generation but also recognize that adding natural gas-fired additions exclusively would, in the long term, create an unbalanced generation portfolio. FPL projects the addition of a new gas-fired unit in 2007 at Turkey Point and new gas-fired units at West County in 2009 and 2010. These units will provide highly efficient generation that will benefit the entire FPL system by reducing transmission related costs, mitigate the load to generation imbalance in the southeast portion of the system and dramatically improve the overall system generation efficiency. FPL plans to compliment these additions with two advanced technology coal units in 2012 and 2013, respectively. The addition of coal-fueled generation will provide fuel supply diversity and assist in stabilizing fuel cost volatility through diversification.

FPL's future resource planning work will remain focused on identifying and evaluating alternatives that would maintain or enhance FPL's long-term fuel diversity. These fuel diversity-enhancing alternatives may include: the purchase of power from new coal-based facilities, obtaining access to diversified sources of natural gas such as LNG, and preserving FPL's ability to utilize fuel oil at its existing units. The evaluation of the feasibility and cost-effectiveness of these, and other possible alternatives, will be an ongoing part of future planning cycles.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2015 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

2. Fuel Price Forecasts

FPL's long-term oil price forecast assumes that worldwide demand for petroleum products will grow moderately throughout the planning horizon. Non-OPEC crude oil supply is projected to increase as new and improved drilling technology and seismic information will reduce the cost of producing crude oil and increase both recoveries from existing fields and new discoveries. However, the rate of increase in non-OPEC supply is projected to be slower than that of petroleum demand, resulting in an increase in OPEC's market share throughout the planning horizon. As OPEC gains market share, prices for crude oil and petroleum products are projected to increase.

FPL's natural gas price forecast assumes that domestic demand for natural gas will grow throughout the planning horizon, primarily due to increased requirements for electric generation. Domestic natural gas production will slowly decline as new and improved drilling technology and seismic information and resulting new finds will only reduce the projected rate of decline in the overall domestic resource base. The rate of decline in domestic natural gas production is projected to be offset by the anticipated increase in U.S. imports from Canada during the next decade, with the development of the MacKenzie Delta region, and the continued increase in re-gasified Liquefied Natural Gas (LNG) imports over the planning horizon. Further enhancement in domestic supply is assumed with the development and delivery of the proven natural gas reserves on the North Slope of Alaska sometime in the next decade.

As demand for natural gas in Florida grows, it is anticipated that the Gulfstream pipeline will fill existing capacity, and along with the Florida Gas Transmission (FGT) pipeline system, expand beyond current capacity to meet the growing requirements of the State of Florida. When coupled with the new Cypress Pipeline from the Elba Island, Georgia LNG Re-gasification Terminal to FGT and the potential for a additional re-gasified LNG Terminal, there is expected to be sufficient natural gas supply for FPL's customers and the State of Florida's continued needs.

FPL's coal price forecast assumes an ample supply of domestic coal, and the availability of imported coal, to meet a gradual but steady increase in U.S. demand in the electric generation sector over the planning horizon. The coal price forecast for FPL's existing coal plants at SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements. FPL's petroleum coke price forecast assumes that the petroleum industry will continue to add coke production facilities in the U.S., as well as in the Caribbean Basin, in order to maximize refinery production of light products. This trend will continue to result in sufficient availability of petroleum coke, at delivered prices significantly below delivered coal prices, to support a gradual, but steady growth in the demand for petroleum coke in the U.S. electric utility industry.

In order to support the proposed coal requirements in the 2012 and 2013 time period, FPL is currently exploring the opportunities for a competitive coal and petroleum coke delivery system. This effort includes the opportunity for competing rail service from Central Appalachia to Florida, a waterborne receiving facility on both the east and west coasts of Florida, and competing rail service from these potential ports to the solid fuel site. A highly competitive coal and petroleum coke delivery network is essential to ensure both the lowest cost and most reliable fuel supply to FPL's customers.

Schedule 5

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated. All values are Summer net MW. The value shown for FPL's unit capability for the Summer of 2006 is an updated projection from the value used in FPL's 2005 analyses.

2/ Total Capacity Available = Col.(2) + Col.(3) - Col.(4) + Col.(5).

3/ These forecasted values reflect the Most Likely forecast without DSM.

4/ The DSM MW shown represent cumulative load management capability plus incremental conservation from 1/2005-on for use with the 2005 load forecast. They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based.

5/ Margin (%) Before Maintenance = Col.(10) / Col.(9)

6/ Margin (%) After Maintenance = Col.(13) / Col.(9)

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All other MW will be picked up in the following year.

Note 2: Changes shown include different ratings than shown in Schedule 1 due solely to ambient temperature consisten with those in FPL 's peak load forecast to maintain consistency in Reserve Margin calculation.

* FPL is currently in the process of selecting a site(s) for these advanced technology coal units. FPL expects to announce the selected site(s) by June 2006.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1)	**Plant Name and Unit Number:**		Turkey Point Combined Cycle Unit # 5
(2)	**Capacity**		
	a. Summer	1,144 MW	
	b. Winter	1,181 MW	
(3)	**Technology Type:**	Combined Cycle	
(4)	**Anticipated Construction Timing**		
	a. Field construction start-date:	2005	
	b. Commercial In-service date:	2007	
(5)	**Fuel**		
	a. Primary Fuel		Natural Gas
	b. Alternate Fuel		Distillate
(6)	**Air Pollution and Control Strategy:**		Natural Gas, Dry Low No_x Combustors, SCR 0.0015% S. Distillate, & Water Injection on Distillate
(7)	**Cooling Method:**		Cooling Tower
(8)	**Total Site Area:**	11,000	Acres
(9)	**Construction Status:**	U	Under Construction, less than or equal to 50% complete
(10)	**Certification Status:**	Certified	
(11)	**Status with Federal Agencies:**	Certified	

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2%	
Forced Outage Factor (FOF):	1%	
Equivalent Availability Factor (EAF):	97%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 97%	(First Base OperationYear)
Average Net Operating Heat Rate (ANOHR):	6,835	Btu/kWh (Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	25	years
Total Installed Cost (2007 $/kW):	507	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):		
Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2007 $kW-Yr)	10.06	
Variable O&M ($/MWH): (2007 $/MWH)	0.13	
K Factor:	1.5699	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9

Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Unsited Simple Cycle Combustion Turbine

(2) **Capacity**
a. Summer 160 MW
b. Winter 181 MW

(3) **Technology Type:** Combustion Turbine

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2007
b. Commercial In-service date: 2008

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Dry Low No_x Burners, Natural Gas 0.0015% S. Distillate and Water Injection on Distillate

(7) **Cooling Method:** Air Coolers

(8) **Total Site Area:** 392 Acres

(9) **Construction Status:** P (Planned)

(10) **Certification Status:** P (Planned)

(11) **Status with Federal Agencies:** P (Planned)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.0%	
Forced Outage Factor (FOF):	1.0%	
Equivalent Availability Factor (EAF):	97%	
Resulting Capacity Factor (%):	Approx. 10%	(First Year Operation)
Average Net Operating Heat Rate (ANOHR):	10,400	Btu/kWh
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	25 years
Total Installed Cost (2008 $/kW):	522
Direct Construction Cost ($/kW):	
AFUDC Amount ($/kW):	
Escalation ($/kW):	
Fixed O&M ($/kW -Yr.): (2008 $kW-Yr)	8.72
Variable O&M ($/MWH): (2008 $/MWH)	0.81
K Factor:	1.8084

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement.

NOTE: Total installed cost includes escalation and AFUDC only.
Transmission interconnection and transmission integration costs are not included.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** West County Energy Center Combined Cycle Unit # 1

(2) **Capacity**
a. Summer 1,219 MW
b. Winter 1,335 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2007
b. Commercial In-service date: 2009

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 220 Acres

(9) **Construction Status:** P (Planned)

(10) **Certification Status:** P (Planned)

(11) **Status with Federal Agencies:** P (Planned)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 97%	(First Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582	Btu/kWh (Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	25	years
Total Installed Cost (2009 $/kW):	565	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):		
Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2009 $kW-Yr)	11.65	
Variable O&M ($/MWH): (2009 $/MWH)	0.138	
K Factor:	1.5834	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** West County Energy Center Combined Cycle Unit # 2

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point Combined Cycle Unit #5

The new Turkey Point CC unit that is scheduled to come in-service in 2007 does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Unsited Combustion Turbine in 2008

No projection of a new transmission line(s) can be made until a site is selected for this unit.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

West County Energy Center Unit #1

The proposed new West County Energy Center Unit #1 that is projected to come in-service in 2009 does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

West County Energy Center Unit #2

The proposed new West County Energy Center Unit #2 that is projected to come in-service in 2010 does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Two Unsited Combustion Turbine Units in 2011

No projection of a new transmission line(s) can be made until a site is selected for these units.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Supercritical Pulverized Coal Unit #1 in 2012

No projection of a new transmission line(s) can be made until a site is selected for this unit.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Supercritical Pulverized Coal Unit #2 in 2013

No projection of a new transmission line(s) can be made until a site is selected for this unit.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Unsited Combustion Turbine in 2014

No projection of a new transmission line(s) can be made until a site is selected for this unit.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Unsited Combustion Turbine in 2015

No projection of a new transmission line(s) can be made until a site is selected for this unit.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Unsited Combined Cycle Unit in 2015

No projection of a new transmission line(s) can be made until a site is selected for this unit.

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in our service area is continuing, which heightens competition for air, land, and water resources that are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among utilities for our commitment to the environment. Our environmental leadership has been heralded by many outside organizations. In 2004 FPL Group earned a first place ranking among U.S. power companies and second globally in a report from the World Wildlife Fund for voluntary commitments to limit CO_2 emissions. This commitment was made to support initiatives to better manage utility impacts on climate change through use of greenhouse gas emission reductions and improvements in energy efficiency. The report stated that this was "primarily due to the company's leadership in developing wind energy and their commitment to dramatically improve their efficiency". As a further demonstration of FPL's efforts in sustainability the EPA and the Department of Energy awarded FPL for its Sunshine Energy Program which allows customers to choose environmentally friendly electricity produced from biomass, wind and solar sources. FPL was also recently awarded its fourth number one rating of major electric utilities surveyed in an environmental assessment conducted by Innovest, an independent advisory group. In recognition of its success in executing a strategy to become a clean energy provider harnessing primarily clean and renewable fuels while also boosting shareholder value, FPL Group, Inc. was named in June 2003 as the winner of the Edison Award, the electric power industry's highest honor by the Edison Electric Institute.

FPL was awarded Edison Electric Institute's National Land Management Award for our stewardship of 25,000 acres surrounding our Turkey Point Plant. FPL won the Council for Sustainable Florida's award for our sea turtle conservation and education programs at our St. Lucie Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. FPL received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise

Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" for our emission-reducing "repowering" projects at our Fort Myers and Sanford Plants. Finally, FPL has been recognized by numerous federal and state agencies for our innovative endangered species programs which include such species as manatees, crocodiles, and sea turtles.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define the Company's position. This statement reflects how FPL incorporates environmental values into all aspects of the Company's activities and serves as a framework for new environmental initiatives throughout the Company. The FPL environmental statement further establishes a long-term direction of environmental initiatives throughout the Company. FPL's Environmental Statement is:

> It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:
>
> - Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
> - Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
> - Encourage the wise use of energy to minimize the impact on the environment.
> - Communicate effectively on environmental issues.
> - Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident/emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with Company policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to: facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and Company policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2005 environmental outreach activities are noted in Table IV.E.1.

Table IV.E.1: 2005 FPL Environmental Outreach Activities

Activity	*# of Participants*
Visitors to Energy Encounter	20,000
Visitors to Manatee Park	150,000
Number of "visits" to FPL's Environmental Website	839,000
Number of pieces of Environmental literature distributed	>120,000

(All numbers are approximations.)

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified two preferred and eight potential sites for future generation additions. Preferred sites are those locations where FPL has conducted significant reviews and taken action to site generation. Potential sites are those sites that have attributes that support the siting of generation and are under consideration as a location for future generation. Some of these sites are currently in use as existing generation sites and some are not. The identification of a "Potential" site does not indicate that FPL has made a definitive decision to pursue generation (or generation expansion in the case of an existing generation site) at that location, nor does this designation indicate that the size or technology of generator has been determined. These preferred and potential sites are discussed in separate sections below.

IV.F.1 Preferred Sites

FPL identifies two preferred sites in this Site Plan: the existing Turkey Point plant site, and the West County Energy Center adjacent to the existing Corbett FPL substation. The Turkey Point site is the location for a capacity addition that FPL is committed to make in mid - 2007. The West County Energy Center site is the projected location for capacity additions FPL is proposing to make in 2009 and 2010.

The capacity addition at the Turkey Point site has been approved by the FPSC. FPL has petitioned the FPSC for approval of the West County Energy Center additions. A decision is expected by the FPSC later this year.

The two preferred sites are discussed below.

<u>Preferred Site # 1: Turkey Point Plant, Miami-Dade County</u>

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear units and two conventional boiler, fossil units, the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the Everglades Mitigation Bank (EMB).

Units #1 and #2 are fossil fuel generating plants with approximate generating capacity of 400 MW each. Unit #1 was completed in 1967 and Unit #2 in 1968. Units #3 and #4 are nuclear generating units with approximate generating capacity of 700 MW each. Unit #3 was completed in 1972 and Unit #4 in 1973. Turkey Point also has five diesel peaking units that in total produce approximately 12 MW. These units are primarily used to provide emergency power, but occasionally run during the Summer to provide power during peak load demands.

The Site for the new Turkey Point Unit #5, a "4-on-1" combined cycle electrical generating unit, is within the existing FPL Turkey Point facility property, located on Biscayne Bay in Miami-Dade County, Florida. The Site is adjacent to the existing fossil Units #1 and #2, and includes the existing parking lot and storage areas immediately northwest of Units #1 and #2 as well as mangrove wetlands north of the facility.

a. and b. <u>U.S. Geological Survey (USGS) Map and Proposed Facilities Layout</u>

A USGS map of the Turkey Point plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. <u>Map of Site and Adjacent Areas</u>

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. <u>Existing Land Uses of Site and Adjacent Areas</u>

A major portion of the site consists of a self-contained cooling canal system that supplies water to condense steam used by the existing units' turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide and approximately four feet deep. The remaining developed area of the site is where the two fossil steam generating units and 5 diesel generators are located. South of and adjacent to the fossil plant are the two nuclear generating units. Further to the south, wetlands have been set aside as part of the Everglades Mitigation Bank (EMB) in an effort to restore these areas to historical plant communities and hydrological function.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the Site was undeveloped dwarf red mangrove swamp, tidally inundated with waters from Biscayne Bay. Along with the dominant red mangroves, buttonwood is a common canopy component, along with occasional white mangrove. Only a few individual black mangroves were observed within the Site. Biscayne Bay is a shallow, subtropical bay supporting seagrasses, sponges, coral reefs, and a variety of marine life.

2. Listed Species

The construction and operation of Unit #5 is not expected to adversely affect any rare, endangered, or threatened species. Listed species known to occur in the nearby Biscayne National Park that could potentially utilize the Site include the peregrine falcon (Falco peregrinus), wood stork (Mycteria americana), American crocodile (Crocodylus acutus), mangrove rivulus (Rivulus marmoratus), roseate spoonbill (Ajaja ajaja), limpkin (Aramus guarauna), little blue heron (Egretta caerulea), snowy egret (Egretta thula), American oystercatcher (Haematopus palliates), least tern (Sterna antillarum), brown pelican (Pelicanus occidentalis), the white ibis (Eudocimus albus), and bald eagle (Haliaeetus leucocephalus). No bald eagle nests are known to exist in the vicinity of the Site. The federally listed, endangered American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the proposed project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing and basking. FPL manages a program for the conservation and enhancement of the American crocodile. A project-specific crocodile management plan has been developed for construction of Unit #5.

3. **Natural Resources of Regional Significance Status**

Significant features in the vicinity on the Site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the Site is included within the Biscayne National Park, comprised of several miles of shoreline north of the Turkey Point facility extending offshore approximately 12 nautical miles. Biscayne National Park contains 180,000 acres, approximately 95% of which is open water interspersed with over 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant, adjacent to the Miami-Dade County Homestead Bayfront Park, which contains a marina and day use recreational facilities.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

Additional generating capacity is being added to the site for operation beginning in 2007 to meet projected FPL system capacity needs. The new generating unit will consist of four new CT's and four new HRSG's and a new steam turbine that will comprise Turkey Point Unit #5. Natural gas delivered via the existing pipeline is the primary fuel type for this unit (with ultra low sulfur light oil serving as a backup fuel). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation for unavoidable wetland impacts related to construction of Unit #5 includes: on-site hydrologic improvements to enhance existing wetlands, restoration and preservation of areas overgrown with exotic plant species, creation of an on-site lagoon, transfer of some mangrove dominated lands to South Florida Water Management District and Biscayne National Park, and also the purchase of mitigation credits from the EMB, which is in the same drainage basin. The capture and reuse of plant process water and rainwater, plus the use of a cooling tower will minimize thermal discharges to the cooling canals. The facility already encompasses several preserved areas where wildlife is abundant.

g. **Local Government future Land Use Designations**

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. **Site Selection Criteria Process**

For the past several years, a number of FPL's existing power plant sites have been considered as potentially suitable sites for new or repowered generation. The Turkey Point plant has been selected as a preferred site due to consideration of various factors including system load, an imbalance in the South Florida region between load and generating capacity, and economics. Environmental issues are an important factor at this site. However, the other deciding factors outweigh them. FPL will minimize environmental impacts and mitigate where impacts are unavoidable.

i. **Water Resources**

Unique to Turkey Point Plant is the self-contained cooling canal system that supplies water to condense steam used by the plant's turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide and approximately four feet deep. The system performs the same function as a giant radiator. The water is circulated through the 153-mile maze of canals in a two-day journey, ending at the plant's intake pumps. During the slow journey down the canals, the water cools as much as 15 degrees

j. **Geological Features of Site and Adjacent Areas**

FPL's Turkey Point site is underlain by approximately 13,000 feet of sedimentary rock strata. The strata that extends to approximately 500 feet forms the Biscayne aquifer. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily of marine origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The Tamiami formation is named for deposits composed principally of white cream-colored calcareous sandstone, sandy limestone, and beds and pockets of quartz sand. In the Turkey Point area, the Key Largo limestone is present.

The Floridan Aquifer, located approximately 1,100 feet below the land surface, is a confined aquifer. The Floridan Aquifer system is composed entirely of carbonate rocks, except for minor evaporates. The water in the carbonate rock aquifer is more highly mineralized.

k. Projected Water Quantities for Various

The additional quantity of water for industrial processing is estimated to be 150 gallons per minute (gpm) for plant process and service water. Water for this type of use would be supplied by an existing county water system. The current plant water treatment system, which provides treated water for use in Units #1 and #2 boilers, would be expanded. Cooling water for new Unit #5 will be processed through a cooling tower. FPL will use approximately 14 million gallons per day (mgd) of water from the Floridan Aquifer as the source of makeup water used by the cooling tower.

l. Water Supply Sources and Type

This additional capacity at the site will utilize the cooling tower for the dissipation of heat from the cooling water. The existing water treatment system at the plant, which provides treated water for use in the Unit #1 and #2 boilers will be expanded to provide treated water for new Unit. The Floridan Aquifer will supply the makeup cooling water.

m. Water Conservation Strategies Under Consideration

A plan to treat and recycle equipment wash water, boiler blowdown, and equipment area runoff for use as service water would reduce ground water consumption. FPL anticipates this site will be designed and classified as a wastewater zero discharge site following the completion of the expansion project.

n. Water Discharges and Pollution Control

Heated water discharges are dissipated using the existing once through cooling water system and the cooling canal system. Unit #5 cooling water will be processed through a cooling tower which will dissipate the heat prior to discharge to the cooling canal system. Non-point source discharges are collected and reused. Treating and recycling equipment wash water, boiler blow-down, and equipment area runoff helps to minimize industrial discharges. Storm water runoff is collected and used to recharge the surficial aquifer via a stormwater management system. Design elements have been included to capture suspended sediments. Various facility permits mandate various sampling and testing activities, which provide indication of any pollutant discharges.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by multiple fuel delivery facilities. There is currently a pipeline that supplies natural gas to the facility. The facility also has oil capabilities through on-site storage tanks and accessibility to barge deliveries. The additional capacity will utilize the existing pipeline with the addition of compression system(s). An above ground storage tank for the ultra-low sulfur light oil backup fuel will be added. The backup fuel for Unit #5 will be delivered to the site by truck.

p. Air Emissions and Control Systems

The use of clean fuels and combustion controls will minimize air emissions from this unit and ensure compliance with applicable emission limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using the ultra-low sulfur light oil as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of Turkey Point Unit #5 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. <u>Noise Emissions and Control Systems</u>

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise would be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will also be within allowable levels. Similar natural gas-fired facilities in Broward and Martin counties have been constructed and operated without exceeding allowable noise levels.

r. <u>Status of Applications</u>

FPL filed the Site Certification Application (SCA) for the Turkey Point Plant Unit #5 with the Florida Department of Environmental Protection (FDEP) on November 14, 2003, and received Site Certification by the Governor and Cabinet in February 2005. The U.S. Army Corps of Engineers issued a federal Dredge and Fill permit in February 2005. FDEP issued the Prevention of Significant Deterioration (PSD) air permit in February 2005. FPL acquired all permits and authorizations needed, and commenced construction in spring 2005 with an anticipated, in-service date of mid 2007.

<u>Preferred Site # 2: West County Energy Center, Palm Beach County</u>

FPL has identified the property adjacent to the existing Corbett Substation property in unincorporated western Palm Beach County as a preferred site for the addition of new generating capacity. The preferred site was selected for the addition of a new greenfield combined cycle natural gas power plant project with ultra-low sulfur oil as a backup fuel. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections. The proposed facility would use clean burning natural gas as the primary fuel and state-of-the-art combustion controls.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the West County Energy Center site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The land on the site is currently inactive but was previously dedicated to industrial and agricultural use. The site has been excavated, back-filled, and totally re-graded to an elevation approximately 10 ft. above surrounding land surface. No structures are present on the site and vegetation is virtually non-existent.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The plant site has been significantly altered by the construction and operation of a limestone mine where vegetation had been cleared and removed. The surrounding land use is predominantly sugar cane agriculture and limestone mining. FPL's existing Corbett substation is located north of the site. The Arthur R. Marshall Loxahatchee National Wildlife Refuge is located to the south of the proposed site.

2. Listed Species

Construction and operation of new units at the site is not expected to affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the mining activities. Common wading birds can be observed on areas adjacent to and occasionally within the property. The property is adjacent to areas that have been identified as potential habitat for wood stork.

3. Natural Resources of Regional Significance Status

The construction and operation of a gas-fired combined cycle generating facility at the proposed location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands including the Arthur R. Marshall Loxahatchee National Wildlife Refuge which lies south of the proposed location. It is not anticipated that construction will result in wetland impacts under federal, state or local agency permitting criteria.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to construct two new 1,200 MW (approximate) units each consisting of three new CT's and three new HRSG's and a new steam turbine. These units are scheduled to be in-service in mid-2009 and 2010. Natural gas delivered via pipeline is the primary fuel type for this unit with ultra-low sulfur light oil serving as a backup fuel. Natural gas-fired facilities are available nearby and are among the cleanest, most efficient technologies currently available.

g. Local Government Future Land Use Designations

Local government future land use designation for the project site is "Rural Residential" according to the Palm Beach County Future Land Use Map. Designations for the area under the Palm Beach County Unified Land Development Code classified the project site and surrounding area as Special Agricultural District. The site has been granted conditional use for electrical power facilities under a General Industrial zoning district.

h. **Site Selection Criteria Process**

The site has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. This site is considered permittable.

i. **Water Resources**

The existing adjacent surface water canals and available ground water resources are potential sources for potable and service water for the proposed units. Adjacent to the site, hydro storage water conservation areas may be created through development of the site as a limestone mine. Use of water from the upper and/or lower Floridan Aquifer is also considered a feasible alternative as potential backup sources of water for operation of the proposed units.

j. **Geological Features of Site and Adjacent Areas**

The site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, clay, and phosphate grains. The deepest formation in Palm Beach County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Oldsmar formation. The published information on the sediments comprising the formations below the Avon Park Limestone is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach Counties.

k. **Projected Water Quantities for Various Uses**

The estimated quantity of water required for industrial processing for both units is approximately 450 gallons per minute (gpm) for uses such as process water and service water. Approximately 20 million gallons per day (mgd) in total of cooling water for the two proposed units would be cycled through the addition of cooling towers. Water quantities needed for other uses such as potable water are estimated to be approximately 35,000 gallons per day (gpd).

l. Water Supply Sources by Type

The proposed units will use available surface or ground water as the source of cooling water for the cooling towers. The cooling towers will also act as a heat sink for the facility process water. Such needs for cooling and process water will comply with the existing South Florida Water Management District (SFWMD) regulations for consumptive water use.

m. Water Conservation Strategies Under Consideration

Impacts on the surficial aquifer would be minimized and used only for potable water. Water will be obtained from the Floridan Aquifer as a source of cooling water as a backup supply. In addition, the entire plant site will capture and reuse process water whenever feasible and manage stormwater in such a manner as to recharge the surficial aquifer.

n. Water Discharges and Pollution Control

Heated water discharges will be dissipated in the cooling towers. Blow down from the cooling towers will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Industrial discharges will be minimized by treating and recycling equipment wash water, boiler blowdown water, and equipment area runoff. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is not located near an existing natural gas transmission pipeline that is capable of providing a sufficient quantity of gas. Upgrades of existing pipelines and/or lateral connections to other pipelines will be necessary for supply of natural gas. Ultra-low sulfur distillate fuel oil would be received by truck and stored in above-ground storage tanks to serve as backup fuel for the new units.

p. Air Emissions and Control Systems

The use of clean fuels and combustion controls will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter and other fuel bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light oil as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the West County Energy Center units will incorporate features that will make them among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will be within allowable levels.

r. Status of Applications

A Site Certification Application (SCA) for the construction and operation of the West County Energy Center project under the Florida Electrical Power Plant Siting Act was filed on April 14, 2005. A Prevention of Significant Deterioration (PSD) permit application and an Underground Injection Control permit application were also submitted to the Florida Department of Environmental Protection (FDEP) at the same time. FDEP issued a Class I Underground Injection Control Exploratory Well permit on January 11, 2006. A petition for approval of a Determination of Need for both West County Energy Center units was filed with the FPSC on March 13, 2006. A Draft PSD Air Permit was issued by FDEP on March 1, 2006.

IV.F.2 Potential Sites for Generating Options

Eight (8) sites are currently identified as "Potential Sites" for near-term future generation additions to meet FPL's capacity needs.[2] These sites have been identified as Potential Sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these potential sites offer a range of considerations relative to engineering and/or costs associated with the construction and operation of feasible technologies. In addition, each potential site has different characteristics that will require further definition and attention. For the purpose of estimating water requirements for each site, it was assumed that either one dual-fuel (natural gas and light oil) simple cycle combustion turbine or a natural gas-fired combined cycle unit would be constructed at the Potential Sites. A simple cycle CT would require approximately 50 gallons per minute (gpm) for both process and cooling water (assuming air cooling). A combined cycle unit would require approximately 150 gpm for service and process water and approximately 14 million gallons per day (mgd) for cooling water.

Permits are presently considered to be obtainable for all of these sites, assuming measures can be taken to mitigate any particular site-specific environmental concerns that may arise. No significant environmental constraints are currently known for any of these eight sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time FPL considers each site to be equally viable.

Potential Site # 1: Andytown Substation, Broward County

FPL has identified the Andytown Substation property in western unincorporated Broward County as a potential site for the addition of new generating capacity. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

[2] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site has been included at the end of this chapter.

b. and c. **Land Uses and Environmental Features**

The land uses for the potential site were designated as industrial or agricultural use. The site identification process included screening to determine potential wetland impacts and impacts to endangered or threatened species. Extensive low-quality wetlands are adjacent to the potential site. FPL would expect to mitigate any impacts from construction of a power plant at this site. Construction and operation of a new facility on this site is not expected to adversely affect any rare, endangered, or threatened species.

d. and e. **Water Quantities and Supply Sources**

Surface water sources are not available at the potential site. Groundwater from the shallow aquifer or a local source of gray water have been identified as potential water sources. The Floridan Aquifer has been identified as a potential cooling water source. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 2: Cape Canaveral Plant, Brevard County

This site is located on the FPL Cape Canaveral Plant property in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway (US 1). A rail line is located near the plant. The existing facility consists of two 400 MW (approximate) steam boiler type generating units.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. and c. **Land Uses and Environmental Features**

This site is located on the Indian River. The land is primarily dedicated to industrial use with surrounding grassy areas and a few acres of remnant pine forest. The land

2006 10-year site plan
Exhibit KRR-3-F, Page 130 of 192

adjacent to the site is dedicated to light commercial and residential use. There are no significant environmental features on the site.

d. and e. Water Quantities and Supply Sources

FPL would use existing on-site wells or local gray water, and the existing once-through cooling water system. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 3: Desoto County Greenfield Site

This site is a "Greenfield" undeveloped site located on a 13,500 acre property in unincorporated Desoto County. The site is adjacent to portions of the Peace River. There are no current facilities on the site. The City of Arcadia is located southwest of the Desoto site.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is currently dedicated to agricultural use (sod farming, cattle grazing, and truck crops). Developed portions of the adjacent properties are primarily agricultural (sod farms, citrus groves and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and a few isolated wetlands.

d. and e. Water Quantities and Supply Sources

The primary sources for water would either be groundwater from the upper and lower Floridan Aquifer or if available and practicable, a local source of gray water. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 4: Fort Myers Plant Site, Lee County

This site is located on FPL's existing 460-acre Fort Myers property. The existing facilities on the site include one 1,440 MW (approximate) combined cycle unit, 12 gas turbines, each with an approximate capacity of 54 MW, and 2 combustion turbines, each with an approximate capacity of 160 MW.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Fort Myers plant site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is currently dedicated to industrial use with surrounding grassy and landscaped areas. Much of the site has recently been used for direct construction activities. The adjacent land uses include light commercial and retail to the east of the property, and some residential areas located toward the west. Mixed scrub with some hardwoods can be found to the east and further south.

d. and e. Water Quantities and Supply Sources

The available water source is the Caloosahatchee River and the available groundwater source is the sandstone aquifer. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 5: Lauderdale Plant, Broward County

The Lauderdale site is located in Eastern Broward County approximately 5 miles inland from Dania Beach and less than 2 miles west of Ft. Lauderdale International Airport. The site is bounded on the south by Dania Cutoff Canal, the east by SW 30th Avenue, and the North by I-595.

The existing 1,680 MW of generating capacity at FPL's Lauderdale site occupies a portion of the approximately 210 acres that are wholly owned by FPL. The generating capacity is made up of two combined cycle units (Units #4 and #5). The site also is home to 24 simple cycle gas turbine (GT) peaking units of 30 MW (approximate) each. The GT's are part of the Gas Turbine Power Park that is made up of 24 GT's at the

Lauderdale Plant site and the twelve GTs at the Port Everglades site. The GT's are capable of firing either natural gas or liquid fuel. The site is considered as suitable for the construction and operation of simple cycle peaking utilizing liquid or natural gas fuels.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The existing power plant facilities are located on approximately 130 acres. The existing site has been in use since the 1920's and is adjacent to a county resource recovery project. To the north of the power plant is an area of mixed uplands with a scattering of small wetlands.

d. and e. Water Quantities and Supply Sources

Existing groundwater or the municipal water supply could be used for industrial process and makeup water. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 6: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District (SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad.

The existing 3,700 MW (Summer) of generating capacity at FPL's Martin site occupies a portion of the approximately 11,300 acres that are wholly owned by FPL. The generating capacity is made up of two steam units (Units #1 and #2), plus three combined cycle units (Units #3, #4, and #8). The site includes a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

a. U.S. Geological Survey (USGS) Map

A USGS map for the site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres. To the east of the power plant there is an area of mixed pine flat wood with a scattering of small wetlands. To the north of the cooling pond there is a 1,200-acre area which has been set aside as a mitigation area. There is a peninsula of wetland forest on the West Side of the reservoir that is named the Barley Barber Swamp. The Barley Barber Swap encompasses 400 acres and is preserved as a natural area. There is also a 10-kilowatt (kW) photovoltaic energy facility at the south end of this site.

d. and e. Water Quantities and Supply Sources

Surface water resources currently used at the Martin facility include the cooling pond which takes its water from the St. Lucie canal. The available ground water resource is the surficial aquifer system which is used as a source of potable and service water. Both of these sources are available for use with any potential site expansion. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 7: Port Everglades Plant, Broward County

This site is located on the 94-acre FPL Port Everglades plant site in Port Everglades, Broward County. The site has convenient access to State Road (SR) 84 and Interstate 595. A rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (approximate) and two 400 MW (approximate) sized units. The four steam boilers are capable of firing residual fuel oil, natural gas, or a combination of both. The site also is home to twelve simple cycle gas turbine (GT) peaking units of 30 MW (approximate) each. The GT's are part of the Gas Turbine Power Park that is made up of 24 GT's at the Lauderdale Plant site and the twelve GTs at the Port Everglades site. The GT's are capable of firing either natural gas or liquid fuel.

a. **U.S. Geological Survey (USGS) Map**

A map of the site is found at the end of this chapter.

b. and c. **Land Uses and Environmental Features**

The land on this site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

d. and e. **Water Resources and Supply Sources**

Cooling water could be drawn from the Intra-coastal Waterway. We believe this source would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 8: Riviera Plant, Palm Beach County

This site is located on the FPL Riviera Plant property in Riviera Beach, Palm Beach County. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (approximate) steam boiler generating units and one retired 50 MW generating unit.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. and c. **Land Uses and Environmental Features**

The land on the site is primarily covered by the existing generation facilities with some open, maintained grass areas. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development. The site is located on the Intra-coastal Waterway near the Lake Worth Inlet.

d. and e. Water Quantities and Supply Sources

The existing municipal water supply could be used for industrial processing water. Industrial cooling water needs could be met using the existing once-through cooling water system. For once-through cooling water, FPL would continue to use Lake Worth as a source of water. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

IV.F.2 Potential Sites for Advanced Technology Coal-Fired Generating Options

As previously discussed, FPL is in the process of analyzing the feasibility of advanced technology coal-fired generating options. FPL believes that the earliest such an option could be permitted and constructed is 2012. FPL's plans to pursue advanced technology coal-fired generation was set forth in its 2005 Request for Proposals (RFP) document issued in September 2005. Part I of the RFP solicited proposals for 2009-2011 that led to FPL's plans to construct the two West County Energy Center units. Part II of the RFP describes FPL's plans to solicit only those proposals that will add to a balanced fuel supply in meeting FPL's 2012-2014 capacity needs. That solicitation is scheduled for later this year.

At the time this Site Plan is being prepared, FPL is analyzing potential sites for such options. Selection criteria for potential sites have been delineated in FPL's *Report on Clean Coal Generation* (March 2005). It is expected that this selection process will have progressed to a point that FPL will be able to share site specific information by June 1, 2006. An Addendum to the 2006 Site Plan will be developed that provides this information when it is available.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance which is available to the FPL system and the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new units that may not adversely impact such limitations. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations, and by, evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system. Both site- and system-related transmission costs are developed for each different unit/unit location option or groups of options.

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's transmission plans are presented in Section III.E.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.[2]

During late 2005, the load forecast was revised upward to incorporate the observed increase in population growth and resulting increase in system demand. This increased forecast, compared to the base forecast used earlier in the year, allowed FPL to bracket a range of expected load growth and the corresponding changes to the generation plan. FPL's response to the increased load was to address the near term needs (2006 - 2008) with a combination of increased DSM, available purchases and securing increased transmission capacity for existing purchases. FPL also identified a single CT in 2008 to meet the balance of the near term needs. In the event the load forecast is reduced, this CT can be avoided or delayed. Should load increase, additional DSM, purchased power or additional self-build CT's may be added to maintain the reliability criteria.

[2] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases (as in most of FPL's current resource planning work), FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its base case or "Most Likely" fuel price forecast are discussed in Chapter III of this document.

FPL conducted an analysis of the comparative economics of a plan that included coal-fired generation compared to an all gas-fired plan. The results of the analysis were presented to the Commission in March, 2005. In this study FPL utilized high, low, and expected or "most likely" fuel cost forecasts to explore the relative system fuel cost differences between a clean coal plan and a plan that included all gas-fired generation additions. This approach allowed FPL to examine the relative economics of these two different types of plans with fuel cost forecasts that varied the price difference between coal and natural gas. Significant changes occurred in long term fuel price forecasts as a result of the events of 2005. Since the natural gas - coal price differential has increased compared to the forecast used in the 2005 Clean Coal Study, it is expected that the economics for coal versus gas have significantly improved.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item #3, FPL used three fuel forecasts in the comparative economic analysis of clean coal generation. FPL held the coal prices constant, based on the most likely coal price forecast, and developed three natural gas price forecasts (high, low, and expected). The low gas price sensitivity, when compared to the coal price forecast, results in an essentially fixed differential between natural gas prices and coal prices.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 and Schedule 8 present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add over the planning horizon is presented on the Schedule 9 forms

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

The key financial assumptions used in FPL's most recent resource planning work were a 45% debt and 55% equity FPL capital structure, projected debt cost of 6.90%, and an equity return of 11.75%. These assumptions resulted in a weighted average cost of capital of 9.57% and an after-tax discount rate of 8.37%. FPL did not test the sensitivity of its resource plan to varying financial assumptions.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). However, in its most recent planning work, FPL utilized both a levelized system average rate perspective for its DSM Goals and DSM Plan work and the equivalent present value of system revenue requirements perspective when evaluating options that did not result in changes to system DSM levels. (As discussed in response to Discussion Item # 2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective are identical when DSM levels are unchanged between competing plans.)

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two system reliability criteria in its resource planning work. One of these is a minimum 20% Summer and Winter reserve margin. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the planning criteria established by the North American Electric Reliability Council (NERC) in its *Planning Standards*. FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Planning Standards* are available on the internet (http://www.nerc.com).

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Facility Rating Methodology* document that are also available on the internet (http://floasis.siemens-asp.com/OASIS/FPL/INFO.HTM).

The normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95/0.95	1.05/1.07
230	0.95/0.95	1.06/1.07
500	0.95/0.95	1.07/1.09

There may be isolated cases for which FPL may determine it prudent to deviate from the general criteria stated above. The overall potential impact on customers and the probability of an outage actually occurring, as well as other factors would influence the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption are revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. Finally, FPL is careful to claim only program savings for the average life of the installed efficiency measure. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

Among the strategic or non-price factors FPL typically considers when choosing between resource options are the following: (1) fuel diversity; (2) technology risk; (3) environmental risk and (4) site feasibility.

Fuel diversity relates to two concepts, the diversity of sources of fuel (e.g., coal vs. oil vs. natural gas), and the diversity of supply for a single fuel source (for example alternative pipeline suppliers for natural gas). All other factors being equal, supply options that increase diversity in fuel source and/or supply would be favored over those that do not.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts. Technologies regarded as more acceptable from an environmental perspective for a plan are those which minimize environmental impacts through highly efficient fuel use and state of the art controls (e.g. clean coal technologies versus conventional pulverized coal).

Site feasibility assesses a wide range of economic, regulatory and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed, elements of FPL's capacity additions include the construction of new generating capacity at an existing site: Turkey Point. This generation construction project was selected after evaluating competing bids received in response to a Request for Proposals (RFP) issued by FPL in mid-2003. The FPSC approved FPL's decision to construct the new combined cycle unit at FPL's existing Turkey Point site in June 2004.

Similarly, FPL's projected capacity additions in 2009 and 2010 at the West County Energy Center site were selected after comparing these units to four bids received in response to an RFP issued in September 2005. FPL has petitioned the FPSC for approval of a Determination of Need for these units. A decision is expected before the end of the year.

The construction capacity additions projected in this document for 2011 and beyond will be conducted in a manner consistent with the Commissions Bid Rule.

Identification of self-build options for 2008 and for 2011 beyond in FPL's Site Plan is not an indication that FPL has pre-judged any capacity solicitation it may conduct. The identification of future capacity units is required of FPL and represents those alternatives that appear to be FPL's best, most cost-effective self-build options at this time. FPL reserves the right to refine its planning analyses and to identify other self-build options. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an

RFP is issued for supply-side resources, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

FPL plans to construct a new transmission line (by July 2006) that was certified under the Transmission Line Siting Act (403.52–403.536, F.S.). The new line will connect FPL's Orange River Substation to FPL's Collier Substation (as shown on Table III.F.1). The final order certifying the corridor was issued on July 19 of 2004. The construction of this line is necessary to serve existing and future customers in the Collier and Lee County areas in a reliable and effective manner. FPL has identified the need for a new 230kV transmission line (by December 2008) that requires certification under the Transmission Line Siting Act. The new line will connect FPL's St. Johns Substation to FPL's proposed Pringle Substation (also shown on Table III.F.1). The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner. FPL has identified the need for a new 230kV transmission line (by December 2011) that requires certification under the Transmission Line Siting Act. The new line will connect FPL's Manatee Substation to FPL's proposed BobWhite Substation (also shown on Table III.F.1). The construction of this line is necessary to serve existing and future customers in the Manatee and Sarasota areas in a reliable and effective manner. Additionally, FPL has identified the need for a new 230kV transmission line (by June 2012) that requires certification under the Transmission Line Siting Act. The new line will connect FPL's future Eve Substation to FPL's Sweatt Substation (also shown on Table III.F.1). The construction of this line is necessary to serve existing and future customers in the Okeechobee and St. Lucie areas in a reliable and effective manner.

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and a disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (FAC).

This Ten Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2006 and that were on-going in the first quarter of 2007. The forecasted information presented in this plan addresses the 2007–2016 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten-year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, as determined in FPL's IRP work in 2006 and early 2007.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as preferred and potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve “discussion items” which pertain to additional specific information that is to be included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2007 Ten Year Power Plant Site Plan (Site Plan) addresses FPL's plans to increase its electric generation capability (owned or purchased) as part of its efforts to meet its projected incremental resource needs for the 2007-2016 time period.

In response to continued strong population growth, FPL's total generation capability is required to increase significantly during the 2007-2016 time period as shown in Table ES.1. The table reflects FPL's planned changes to existing generation units (due to unit overhauls, etc.), projected changes in the delivered amounts of purchased power, and the planned additions of new generating units. Although not explicitly shown in this table, FPL's demand side management (DSM) resources are included. These resources incorporate the approved DSM Goals (that are assumed to be implemented on schedule) and approximately 684 MW of additional DSM that FPL projects will be implemented through 2016. This represents approximately 1,486 MW of cost-effective DSM beyond the significant amount of DSM achieved by FPL through 2006. After accounting for FPL's 20% reserve margin requirement, these 1,486 MW of additional DSM will avoid the need for approximately 1,780 MW of additional generating capacity that otherwise would be needed.

In 2007, FPL will be adding a new 1,144 MW (Summer) combined cycle (CC) unit, Turkey Point Unit #5, at its existing Turkey Point plant site. In 2009, and again in 2010, FPL will be adding one 1,219 MW (Summer) CC unit in western Palm Beach County. The site is named the West County Energy Center (WCEC) and these units are identified as West County Energy Center Units #1 and #2 (WCEC #1 and # 2). All three of these CC units were approved by the Florida Public Service Commission (FPSC). The Turkey Point unit was approved by the FPSC in June 2004 and the two WCEC units were approved in June 2006. FPL's applications for site certification under the Florida Electric Power Plant Siting Act were approved by the Governor and Siting Board in February 2005 for the Turkey Point unit and in December 2006 for the WCEC units. The addition of these three highly efficient units will meet FPL's capacity needs through 2010.

FPL plans to address its capacity needs in years 2013 and 2014 with two new ultra-supercritical pulverized coal (USCPC) units. For planning purposes, these units are projected to be in service by June 2013 and June 2014, respectively. However, FPL intends to bring these advanced technology coal units in service as quickly as possible in order to maintain system fuel diversity and reduce system fuel costs. It is likely that the in-service date of the first USCPC unit will occur in late 2012 or early 2013 and likewise, that the in-service date of the second USCPC unit will likely occur in late 2013 or early 2014. The new units will be located in FPL Glades Power Park

(FGPP) located in Glades County and are identified as FGPP Units #1 and #2. FPL filed a petition with the FPSC for a determination of need for the two FGPP coal units on February 1, 2007 and a decision is expected from the FPSC by July 2007.

In addition to the capacity needs to be met by the addition of Turkey Point Unit #5, WCEC Units #1 and #2, and FGPP Units #1 and #2, FPL currently projects capacity needs in 2011 (167 MW), in 2012 (777 MW), in 2013 (214 MW), in 2015 (323 MW), and in 2016 (1,327 MW). These capacity needs will be met by a combination of resources including: additional cost-effective DSM, power purchases, enhancements to existing generating units, and new power plant construction.[1] At the time this document is filed, no decision is needed regarding how these additional capacity needs will be met. FPL will continue to analyze alternatives that could be implemented to meet its projected capacity needs as part of its on-going resource planning work in 2007 and subsequent years. This future analysis work will take into account a number of factors including: the outcome of FPL's petition for need determination and site certification for FGPP Units #1 and #2, changes in forecasts of load, fuel costs, and environmental compliance costs to the extent reasonably ascertainable, and changes in both supply and demand side options.

For purposes of this planning document, FPL anticipates that the remaining projected capacity needs for the years 2011, 2012, and 2013 will be met by short-term firm power purchases of 167

MW, 800 MW, and 200 MW, respectively. Power purchases of these magnitudes are currently projected to be available for these years. FPL also projects, for purposes of this planning document, the addition of a new 1,219 MW CC unit similar to the WCEC CC units in 2015. A specific site for this potential addition has not yet been determined and the unit is referred to in this document as South Florida CC #1. The addition of this unit, or an equivalent amount of capacity, would meet FPL's capacity needs in 2015 and 2016.

FPL's ongoing resource planning efforts will continue to be influenced by two recurrent issues. Those two issues are: (1) maintaining fuel diversity in the FPL system; and (2) maintaining a balance between load and generating capacity in Southeast Florida. In regard to the first issue, the addition of the FGPP Units #1 and #2 coal units will maintain fuel diversity on FPL's system by maintaining the contribution of coal generation and limiting the increase in reliance on natural gas. FPL is also actively investigating the potential for renewable energy in Florida to contribute to system fuel diversity.

[1] Repowering of existing FPL sites remains an alternative to new construction and FPL will continue to examine this option.

Also in regard to the first issue, FPL is undertaking steps to investigate the next generation of nuclear generation facilities. Although the feasible in-service date for new nuclear generation is beyond the planning horizon of this Site Plan, FPL is actively pursuing the possibility of new nuclear generation. In regard to the second issue, the addition of Turkey Point Unit #5, and WCEC Units #1 and #2, will help maintain a balance of generation located in the Southeast area with that region's load, and contribute to overall system reliability.

Table ES.1: Projected Capacity Changes and Reserve Margins for FPL [1]

Projected Capacity Changes and Reserve Margins for FPL [1]		Net Capacity Changes (MW)		FPL Reserve Margin (%)	
		Winter[2]	Summer[3]	Winter	Summer
2007	Turkey Point Unit #5 [5]	---	1,144	26.4%	22.6%
	Changes to Existing Units	16	(2)		
	Changes to Existing Purchases [4]	657	(387)		
2008	Turkey Point Unit #5 [5]	1,181	---	26.5%	20.5%
	Changes to Existing Units	28	27		
	Changes to Existing Purchases [4]	(836)	---		
2009	West County Unit #1 [5]	---	1,219	22.8%	20.9%
	Changes to Existing Units	28	1		
	Changes to Existing Purchases [4]	(326)	(482)		
2010	West County Unit #1 [5]	1,335	---	24.3%	22.1%
	West County Unit #2 [5]	---	1,219		
	Changes to Existing Purchases [4]	(512)	(405)		
2011	West County Unit #2 [5]	1,335	---	27.7%	20.0%
	Power Purchase in 2011		167		
	Changes to Existing Purchases [4]	(94)	(45)		
2012	Changes to Existing Purchases [4]	---	(156)	25.5%	20.1%
	Changes to Power Purchase in 2011	---	(167)		
	Power Purchase in 2012	---	800		
2013	FGPP Unit # 1 [5]	---	980	22.6%	19.9%
	Changes to Power Purchase in 2012	---	(800)		
	Power Purchase in 2013	---	200		
	Changes to Existing Purchases [4]	(180)	---		
2014	FGPP Unit # 1 [5]	990	---	24.9%	21.3%
	FGPP Unit # 2 [5]	---	980		
	Changes to Power Purchase in 2013	---	(200)		
2015	FGPP Unit # 2 [5]	990	---	26.1%	23.7%
	South Florida CC #1 [5]	---	1,219		
2016	South Florida CC #1 [5]	1,335	---	27.1%	19.6%
	Changes to Existing Purchases [4]	(390)	(381)		
	TOTALS =	5,557	4,931		

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of year shown.
(3) Summer values are values for August of year shown.
(4) These are firm capacity and energy contracts with QF, Utilities and other purchases. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.6 million people. FPL served an average of 4,409,563 customer accounts in thirty-five counties during 2006. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management, and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, FL. The current generating facilities consist of four nuclear steam units, three coal units, eleven combined cycle units, seventeen fossil steam units, forty eight combustion gas turbines, one simple cycle combustion turbine, and five diesel units. The location of these units is shown on Figure I.A.1 and in Table I.A.1.

FPL's bulk transmission system is comprised of 6,620 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 542 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

FPL Generating Resources by Location

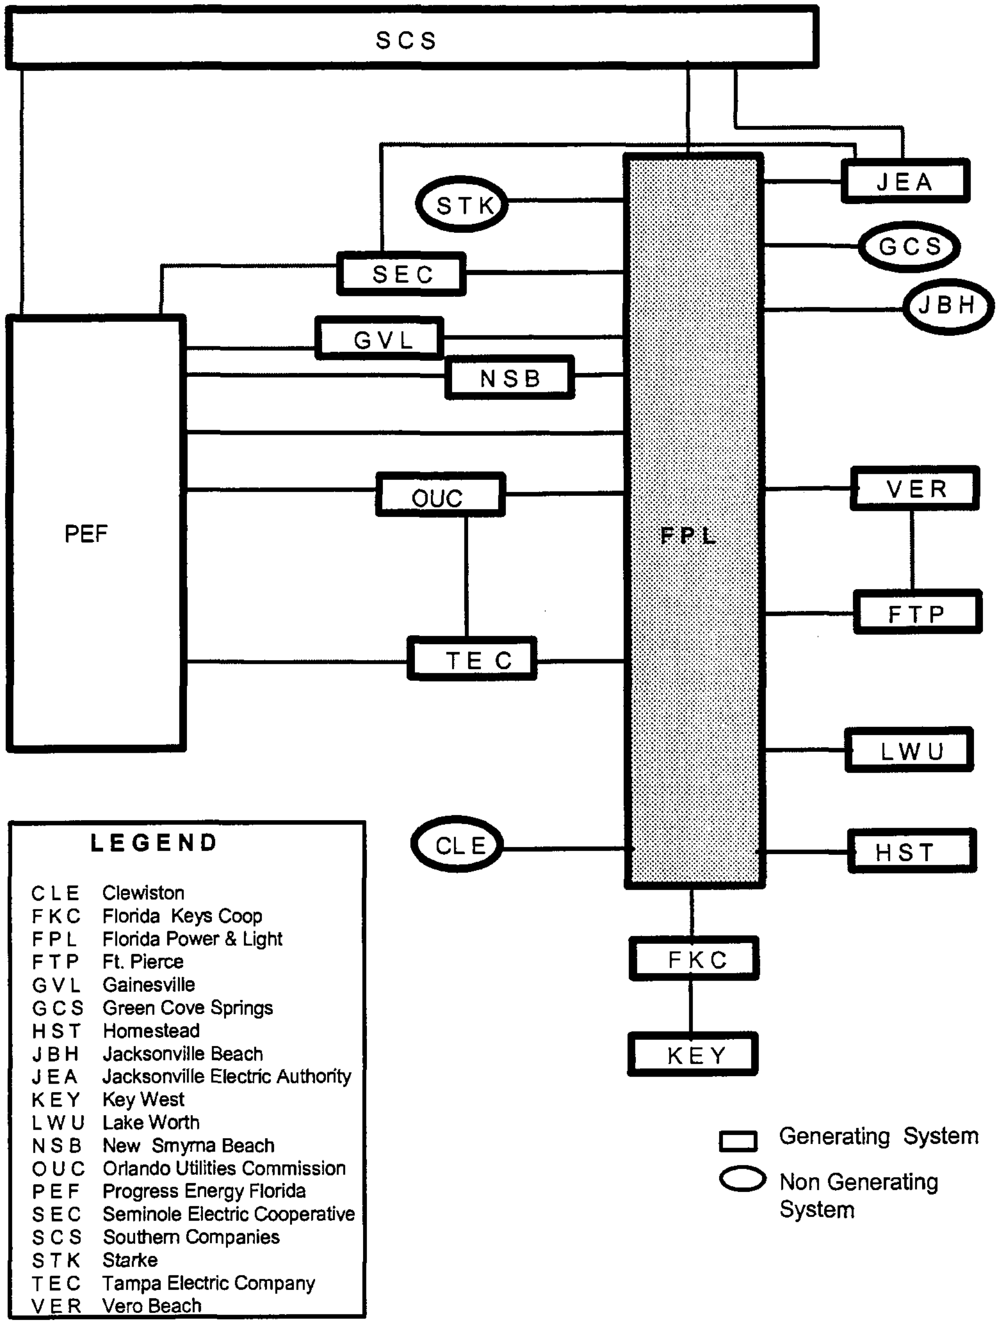

Figure I.A.3: FPL Interconnection Diagram

I.B Firm Capacity Power Purchases

Purchases from Qualifying Facilities (QF):

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five qualifying facilities; i.e., cogeneration/small power production facilities, to purchase firm capacity and energy.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Purchases from Utilities:

FPL has a Unit Power Sales (UPS) contract to purchase 931 MW, with a minimum of 381 MW, of coal-fired generation from the Southern Company (Southern). through May, 2010. An additional contract with Southern will result in FPL receiving 930 MW from June 2010 through the end of 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units. For planning purposes, FPL is projecting a subsequent purchase of the same amount of MW from north of Florida starting in 2016.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 381 MW (Summer) and 390 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. (FPL also has ownership interest in these units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.)

Other Purchases:

FPL has other firm capacity purchase contracts through 2009 with a variety of Non-QF suppliers. These purchases are generally near-term in nature. Table I.B.1 and I.B.2 present the Summer and Winter MW, respectively, resulting from all firm purchased power contracts discussed above through the year 2016 as well as other purchases in 2011 – 2013 assumed in this document for planning purposes.

I.C Non-Firm (As Available) Energy Purchases

FPL purchases non-firm (as-available) energy from several cogeneration and small power production facilities. Table I.C.1 shows the amount of energy purchased in 2006 from these facilities.

Table I.C.1: As Available Energy Purchases From Non-Utility Generators in 2006

I.D. Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include both conservation initiatives and load management. FPL's DSM efforts through 2006 have resulted in a cumulative Summer peak reduction of approximately 3,659 MW at the generator and an estimated cumulative energy saving of approximately 38,169 Gigawatt Hour (GWh) at the generator. Accounting for reserve margin requirements, FPL's DSM efforts through 2006 have eliminated the need to construct the equivalent approximately 11 new 400 MW generating units.

Table I.D.1 presents FPL's approved DSM Goals for Summer MW reduction. These DSM Goals are over and above the significant levels of DSM implementation FPL achieved before the year 2005. FPL's current DSM Plan was approved by the Commission in 2004 and was designed to achieve the DSM Goals for the 2005–2014 time periods.

In addition, FPL recently received approval from the Commission to modify 8 existing DSM programs and to introduce two new DSM programs. These additional efforts will result in a projected increase of 564 Summer MW at the generator of additional DSM beyond FPL's DSM Goals by 2015 as is also presented in Table I.D.1. The table shows that when these additional 564 MW of DSM are added to the 802 MW of DSM Goals at the generator from 2006 – 2015, FPL is adding 1,366 MW at the generator of cost-effective DSM by 2015.

For planning purposes, FPL is also assuming a continuation of DSM implementation in 2016 and projects the addition of approximately 120 MW of incremental DSM in that year so that through 2016 FPL currently projects 1,486 MW of cost-effective DSM beyond the significant amount of DSM achieved by FPL through 2006.

Table I.D.1. : FPL's DSM Goals and Additional DSM: 2006 – 2015 (Summer MW)

Year	(1) DSM Goals 2005 - 2015 Summer MW at Meter (1)	(2) = (1) /(1-0.0923) DSM Goals 2005 - 2015 Summer MW at Generator (2)	(3) DSM Goals 2006 - 2015 Summer MW at Generator (3)	(4) Additional DSM 2006 - 2015 Summer MW at Generator (4)	(5) = (3) + (4) 2006 - 2015 Total Projected Summer MW at Generator (5)
2005	74.0	82	---	---	---
2006	141.7	156	75	39	114
2007	211.9	233	152	229	381

2011	532.1	586	505	413	918
2012	618.8	682	600	456	1,056
2013	707.9	780	698	501	1,199
2014	801.7	883	802	548	1,350
2015	801.7	883	802	564	1,366

Notes: (1) The Commission-approved DSM Goals address 2005 - 2014 and represent DSM MW at the meter.

(2) The DSM Summer MW at the Generator are approximate values based on a 9.23% line loss factor.

(3) These values represent DSM Goals values from 2006 through 2015 and omit the 2005 Goals values.

(4) The values shown above for 2006 through 2008 were originally presented in FPL's 2006 Ten Year Site Plan in Table III.D.2 on page 62. Those values represented the additional DSM MW contribution through 2008 at the time the Site Plan was filed. The 2009 - on values represent a current projection of additional DSM due to FPSC approval in mid-2006 of modifications to existing FPL DSM programs and of new DSM programs.

1/ These ratings are peak capability.
2/ These ratings represent Florida Power & Light Company's share of Scherer Unit No. 4, adjusted for transmission losses.
3/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Unit No. 1 and No. 2, excluding Jacksonville Electric Authority (JEA) share of 80%.
4/ Total capability of each unit is 853/839 MW. FPL's ownership share of St. Lucie 1 and 2 is 100% and 85% respectively.Capabilities shown represent FPL's share of capacity from each of the units (approx. 92.5%) and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are developed on an annual basis for resource planning work at FPL. These forecasts are a key input to the models used to develop FPL's Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

The primary drivers to develop these forecasts are demographic trends, weather, economic conditions, and prices of electricity. In addition, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from the National Oceanic and Atmospheric Administration (NOAA), and inputs from FPL's own customer service planning areas. In the area of demographics, population trends by county, plus housing characteristics such as housing starts, housing size, and vintage of homes are assessed.

Forecasts for electric usage in the residential and commercial classes include end-use information such as appliance saturation studies, efficiencies, and intensity of energy use. In addition to these inputs, residential forecasts also make use of household characteristics such as ages of members in households, number of members in households, and income distributions.

The projections for the national and Florida economy are obtained from Global Insight. Population projections for the counties served by FPL are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. In addition, FPL actively participates with local development councils and universities to obtain their assessments of the local economy, specifically in the area of expansion of new businesses and retention of the current business base. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects the company's sales and peak demand. Weather variables are used in the forecasting models for energy sales and peak demand. There are two sets of weather variables developed and used in forecasting models:

1. Cooling and Heating Degree-Days are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. A composite temperature hourly profile is derived using hourly temperatures across FPL's service territory (Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained) weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Days which are based, respectively, on starting point temperatures of 65°F and an additional cooling degree variable based on a temperature of 75°F degrees. Similarly, composite temperature and hourly profile of temperature are used for the Summer and Winter peak models.

II.A. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class for the forecasting period of 2006-2025 and are adjusted to match the Net Energy for Load (NEL) forecast. The results of these sales forecasts for the years 2007-2016 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and Net Energy for Load forecast are outlined below.

1. **Residential Sales**

   Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, real Florida personal income, Cooling and Heating Degree-Days as explanatory variables, as well as a dummy variable for hurricanes and other outliers. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. To capture economic conditions, the model includes Florida's Real Personal Income. The degree of economic prosperity can, and does, affect residential electricity sales. The impact of weather is captured by the Heating Degree-Days and Cooling Degree-Days. Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted.

2. **Commercial Sales**

The commercial sales forecast is also developed using a regression model. Commercial sales are a function of the following variables: Real Gross Domestic Product, commercial real price of electricity, Cooling Degree-Days, as well as dummy variables for hurricanes and outliers. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree-Days are used to capture weather-sensitive load in the commercial sector.

3. **Industrial Sales**

Industrial sales were forecasted using a linear multiple regression model. The linear multiple regression model utilizes the following variables: Gross Domestic Product, Cooling Degree-Days, and several dummy variables for outliers, hurricanes, and months. The Cooling Degree-Day term is used to capture the weather-sensitive load in the industrial class.

4. **Other Public Authority Sales**

The sales for other public authority sales are developed using an econometric model with Cooling Degree-Days and several dummy variables for outliers.

5. **Street & Highway Sales and Railroad & Railways Sales**

The forecast for street and highway sales is developed using an econometric model with Real Domestic Gross Product as the primary driver and several variables for outliers. Similarly the forecast of sales to railroad & railways is developed using an econometric model with the Florida population as the primary driver and several monthly dummy variables to capture seasonality. This class consists solely of the Miami-Dade County's Metrorail system.

6. **Sales for Resale**

Sales for resale (wholesale) customers are composed of municipalities and/or electric cooperatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Currently, there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of Key West, Florida (City of Key West), Miami-Dade County, and the Florida Municipal Power Agency (FMPA)[2]. Sales to the Florida Keys are forecasted using a regression model. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor. Miami-Dade County sells 60 MW to Progress Energy. Line losses are billed to Miami-Dade under a wholesale contract. FMPA has contracted for delivery of 75 MW from FPL through October, 2007.

7. **Total Sales**

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual Net Energy for Load (NEL).

II.B. Net Energy for Load

An econometric model is developed to produce a net energy for load (NEL) forecast. The key inputs to the model are: the real price of electricity, Heating and Cooling Degree-Days, and Florida Real Personal Income.

Once the NEL forecast is obtained using the above-mentioned methodology, the results are then compared for reasonableness to the NEL forecast generated using the total sales forecast. The sales by class forecasts previously discussed are then adjusted to match the NEL from the annual NEL model.

The forecasted NEL values for 2007 – 2016 are presented in Schedule 3.3 that appears at the end of this chapter.

II.C. System Peak Forecasts

The rate of absolute growth in FPL system load has been a function of a growing customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the peak forecast models to capture these behavioral relationships.

[2] At the time this document is being prepared, FPL is in discussion with Lee County Electric Co-Operative (Lee County) regarding potential wholesale service by FPL to Lee County. If such an agreement is reached, FPL will list the agreement and incorporate its impacts in future Site Plans.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2007–2016 are presented in Schedules 3.1 and 3.2 as well as in Schedules 7.1 and 7.2.

System Summer Peak

The Summer peak forecast is developed using an econometric regression model. This econometric model utilizes the following explanatory variables: total average customers, the real price of electricity, Florida Real Personal Income, average temperature on peak day, and a heat buildup weather factor consisting of the sum of the Cooling Degree - Hours during the peak day and three prior days.

System Winter Peak

The Winter peak forecast is developed using the same econometric regression methodology as is used for Summer peak forecasts. The Winter peak model is a per customer model which contains the following explanatory variables: the square of the minimum temperature on the peak day and Heating Degree-Hours for the prior day as well as for the morning of the Winter peak day. The model also includes an economic variable: Florida Real Personal Income.

Monthly Peak Forecasts

Monthly peaks for the 2006-2025 period are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peaks (Summer = April-October, Winter = November-March.)

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.D. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2006-2025 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

2014	26,100	110	25,990	0	1,110	430	837	274	23,449
2015	26,772	110	26,662	0	1,139	486	852	312	23,982
2016	27,410	110	27,300	0	1,175	505	864	347	24,499

Historical Values (1997 - 2006):

Col. (2) - Col. (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 1997 through 2006 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial /Industrial Demand Reduction (CDR). Col.(5) - Col.(9) for year 2004 are "estimated actuals" and are August values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8).

***Projected Values* (2007 - 2016):**

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col. (9) represent all incremental conservation and cumulative load control. These values are projected August values and the conservation values are based on projections with a 1/2006 starting point for use with the 2006 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.2

2015/16	26,692	110	26,582	0	1,105	253	719	112	24,504
2016/17	27,342	110	27,232	0	1,131	280	726	127	25,078

Historical Values (1997 - 2006):

Col. (2) - Col. (4) are actual values for historical winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col.(9) for 1996/97 through 2005/06 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial/Industrial Demand Reduction (CDR).Col.(5) - Col.(9) for year 2004/05 are "estimated actuals" and are January values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col. (2) - Col. (6) - Col. (8).

Projected Values (2007/08- 2015/16):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col.(9) represent all incremental conservation and cumulative load control. These values are projected January values and the conservation values are based on projections with a 1/2004 starting point for use with the 2004 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

2013	142,379	742	429	141,345	1,034	10,121	141,208	63.3%
2014	146,257	850	488	145,223	1,034	10,396	144,918	64.0%
2015	150,291	959	548	149,258	1,034	10,675	148,785	64.1%
2016	154,556	963	550	153,522	1,034	10,940	153,042	64.4%

Historical Values (1997 - 2006):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: Col. (2) = Col. (3) + Col. (4) + Col. (8).

Col.(3) & Col.(4) for 1997 through 2006 are DSM values starting in January 1988 and are annual (12-month) values.Col. (3) and Col. (4) for 2006 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWH reductions actually experienced each year .

Col. (5) & Col. (6) are a breakdown of Net Energy For Load in Col (2) into Retail and Wholesale.

Col. (9) is calculated using Col. (8) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (8)*1000) / ((Col.(2) * 8760)

Projected Values (2007 - 2016):

Col. (2) represents Net Energy for Load w/o DSM values. The values are extracted from Schedule 2.3, Col. (19).

Col. (3) & Col. (4) are forecasted values of the reduction on sales from incremental conservation and are mid-year (6-month) values. The effects of conservation implemented prior to 2006 are incorporated into the load forecast.

Col. (5) & Col. (6) are a breakdown of Net Energy For Load in Col (2) , into Retail and Wholesale.

Col. (8) NEL projected values shown here do include the impact of conservation in Col. (3) and Col. (4). Therefore, these NEL values **do not match** those shown on schedule 2.3 because those values do not account for incremental conservation.

Col. (9) is calculated using Col. (2) from this page and Col. (2), "Total", from Schedule 3.1. Col. (9) = ((Col. (2)*1000) / ((Col. (2) * 8760)
Adjustments are made for leap years.

Schedule 4
Previous Year Actual and Two-Year Forecast of
Retail Peak Demand and Net Energy for Load (NEL) by Month

(1)	(2)	(3)	(4)	(5)	(6)	(7)
	2006 ACTUAL		2007* FORECAST		2008* FORECAST	
Month	Total Peak Demand MW	NEL GWH	Total Peak Demand MW	NEL GWH	Total Peak Demand MW	NEL GWH
JAN	14,800	8,059	22,247	8,439	22,627	8,811

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990s and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of potential new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2006 and early 2007 resource planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Determine the economics for the total utility system with each of the competing options and resource plans; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

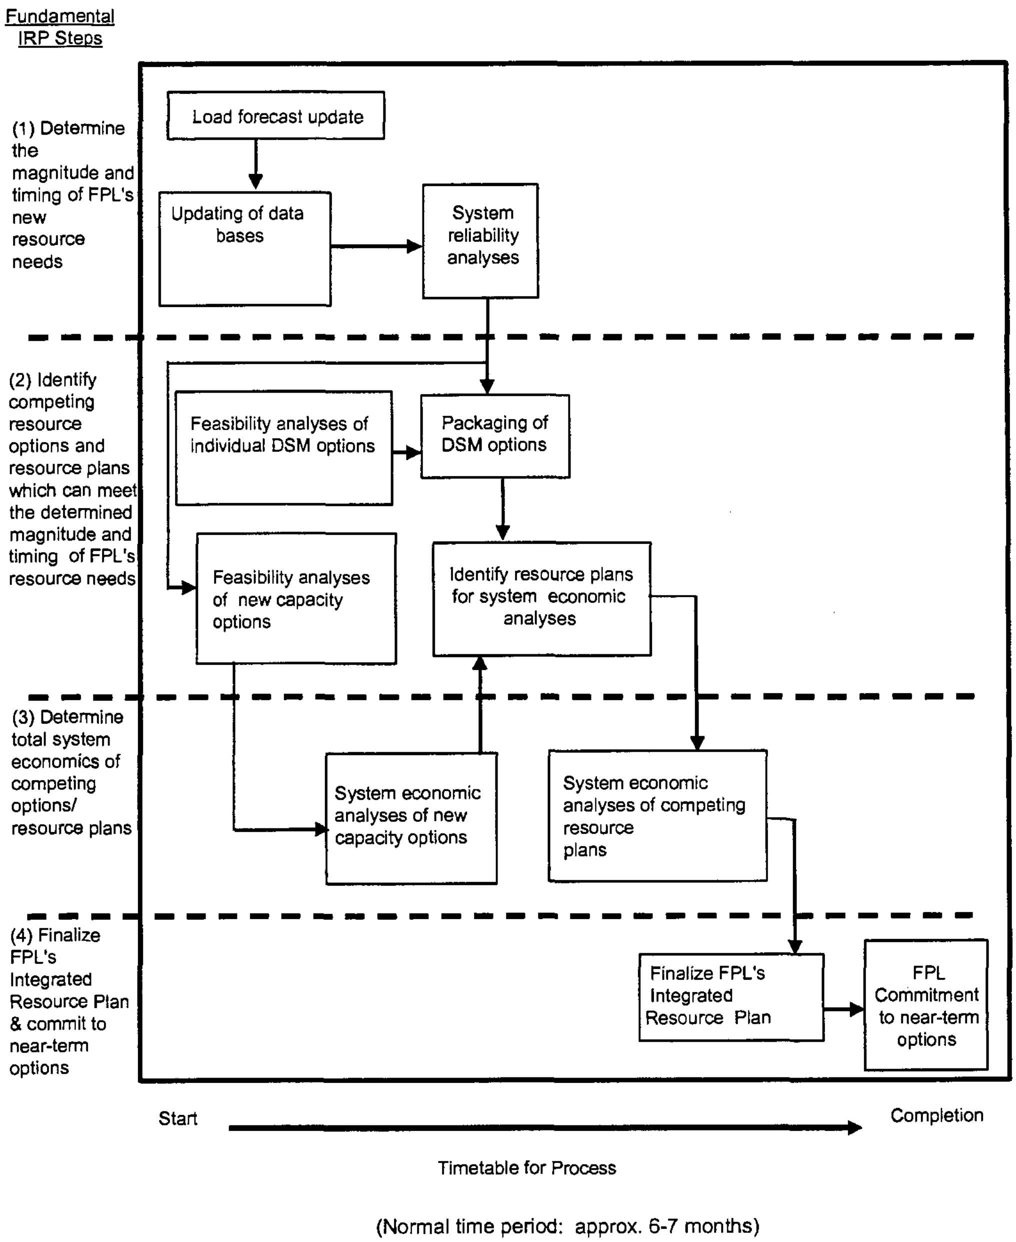

Figure III.A.1: Overview of FPL's IRP Process

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps, determining the magnitude and timing of FPL's resource needs, is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a reliability, or resource adequacy, assessment for the utility system.

Step 1 typically starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information that is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) firm capacity power purchases, and (3) DSM implementation.

The first of these assumptions is based on FPL's ongoing engineering and construction activities to add near-term capacity. These construction activities include three new combined cycle (CC) units: one at FPL's Turkey Point site scheduled to come in-service by mid-2007 and two at FPL's West County Energy Center (WCEC) site scheduled to come in-service by mid-2009 and mid-2010 respectively. FPL selected these CC options after conducting separate Request for Proposals (RFP) solicitations and evaluating the options received in response to the RFPs. These additions were subsequently approved by the FPSC and the Governor and Siting Board.

The second of these assumptions involves firm capacity power purchases. These firm capacity purchases are from a combination of utility and independent power producers. Details, including the annual total capacity values for these purchases are presented in Tables I.B.1 and I.B.2. These purchased capacity amounts were incorporated in FPL's recent resource planning work.

The third of these assumptions involves DSM. Since 1994, FPL's resource planning work has assumed that the DSM MW called for in FPL's approved DSM Goals will be achieved per plan. This was again the case in FPL's most recent planning work as its new DSM

Goals that address the years 2005 through 2014, and that were approved by the FPSC in August 2004, are assumed to be achieved per plan.

In addition, FPL recently received approval from the Commission to modify 8 existing DSM programs and to introduce two new DSM programs. These efforts will result in a projected increase of 564 Summer MW at the generator of additional DSM and curtailable beyond FPL's DSM Goals by 2015. In addition, FPL is also assuming a continuation of DSM implementation in 2016 and projects the additions of approximately 120 MW of incremental DSM in that year so that through 2016 FPL currently projects 1,486 MW of cost-effective DSM beyond the significant amount of DSM achieved by FPL through 2006. These additional MW of DSM were also accounted for prior to making projections of new resource needs.

These key assumptions, plus the other updated information, are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its native load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the generation resource adequacy of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss–of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program used by FPL.

The result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. Information regarding the timing and magnitude of these resource needs is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analyses of new capacity options are conducted to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs. In similar analyses, feasibility analyses of new DSM options and/or continued growth in existing DSM options, are conducted.

The individual new resource options emerging from these feasibility options are then typically "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is frequently carried out using dynamic programming techniques.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs are identified.

Step 3: Determining the Total System Economics:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for comparing the system economics of these resource plans. In its 2006 resource planning work, FPL performed some of this work of combining resource options into resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI). The EGEAS model was also used to perform basic economic analyses of resource plans. For various analyses, including the analyses of the advanced technology coal option, FPL utilized the P-MArea production cost model and a Fixed Cost Spreadsheet to develop a more detailed perspective of costs for the various resource plans developed to analyze the advanced technology coal option. The P-MArea model is the model used by FPL to develop the Fuel Cost Budget and to conduct other production cost-related analyses.

In 2006, FPL also utilized several other models in its resource planning work. For DSM analyses, FPL used its DSM cost-effectiveness model; an FPL spreadsheet model utilizing the FPSC's approved methodology for analyzing the cost-effectiveness of individual DSM measures/programs, and its non-linear programming model for analyzing the potential for lowering system peak loads through additional load management capacity.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases in which the DSM contribution was assumed as a given and the only competing options were new generating units and/or purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans were evaluated on a cumulative present value revenue requirement (CPVRR) basis.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps were used to develop the future generation plan. This plan is presented in the following section.

III.B Incremental Resource Additions

FPL's projected incremental generation capacity additions/changes for 2007 through 2016 are depicted in Table III.B.1 (the planned DSM additions through 2015 were shown previously in Table I.D.1). These capacity additions/changes result from a variety of actions including: changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, and by projected construction of new generating units.

As shown in Table III.B.1, the capacity additions are largely made up of committed new construction, new purchases, and proposed self-build alternatives. (The additional DSM MW are not presented in this table but have been accounted for prior to making these new capacity option projections.) FPL included its previously committed generation construction projects in its 2006 reliability assessment. These committed construction projects are the new 1,144 MW combined cycle (CC) unit at FPL's existing Turkey Point plant site (Turkey Point Unit #5) that will be placed into service in mid-2007, the new 1,219 MW CC unit at the West County Energy Center (WCEC) that is scheduled to be placed into service in mid-2009 (WCEC Unit #1), and a second 1,219 MW CC unit at WCEC (WCEC Unit #2) that is scheduled to be placed into service in mid-2010.

FPL also projects the construction of two new advanced technology coal units; one each by 2013 and 2014 at FPL's Glades Power Park (FGPP) site in Glades County. These two units will use ultra-supercritical pulverized coal (USCPC) technology in concert with advanced emissions controls to address FPL's resource needs for 2013 and 2014 and to maintain fuel diversity on FPL's system. FPL filed for FPSC approval of these two advanced technology coal units on February 1, 2007. The FPSC is expected to render its decision by July 2007.

These additions of the Turkey Point, WCEC, and FGPP units will meet a significant portion of FPL's projected resource needs through 2016 and will maintain fuel diversity on FPL's system. After accounting for these capacity additions, FPL projects a remaining small (167 MW) resource need in 2011 and more significant resource needs in 2012 (777 MW), 2013 (214 MW), 2015 (323 MW), and 2016 (1,327). No decisions are currently needed in regard to how FPL will meet those needs and FPL will consider additional cost-effective DSM, power purchases, enhancements to FPL's existing units, and new generation construction as options with which to meet those needs.

For purposes of this planning document, FPL projects short-term firm capacity purchases of 167 MW in 2011, 800 MW in 2012, and 200 MW in 2013 to meet the remaining capacity needs in those years. Also projected is the addition of a new 1,219 MW unsited CC unit (labeled as "South Florida CC") similar to the WCEC CC units in 2015 to meet the remaining capacity need in 2015 and 2016.

Table III.B.1: Projected Capacity Changes for FPL [1]

Projected Capacity Changes for FPL [1]		Net Capacity Changes (MW) Winter [2]	Net Capacity Changes (MW) Summer [3]
2007	Turkey Point Unit #5 [5]	---	1,144
	Changes to Existing Units	16	(2)
	Changes to Existing Purchases [4]	657	(387)
2008	Turkey Point Unit #5 [5]	1,181	---
	Changes to Existing Units	28	27
	Changes to Existing Purchases [4]	(836)	---
2009	West County Unit #1 [5]	---	1,219
	Changes to Existing Units	28	1
	Changes to Existing Purchases [4]	(326)	(482)
2010	West County Unit #1 [5]	1,335	---
	West County Unit #2 [5]	---	1,219
	Changes to Existing Purchases [4]	(512)	(405)
2011	West County Unit #2 [5]	1,335	---
	Power Purchase in 2011		167
	Changes to Existing Purchases [4]	(94)	(45)
2012	Changes to Existing Purchases [4]	---	(156)
	Changes to Power Purchase in 2011	---	(167)
	Power Purchase in 2012	---	800
2013	FGPP Unit # 1 [5]	---	980
	Changes to Power Purchase in 2012	---	(800)
	Power Purchase in 2013	---	200
	Changes to Existing Purchases [4]	(180)	---
2014	FGPP Unit # 1 [5]	990	---
	FGPP Unit # 2 [5]	---	980
	Changes to Power Purchase in 2013	---	(200)
2015	FGPP Unit # 2 [5]	990	---
	South Florida CC #1 [5]	---	1,219
2016	South Florida CC #1 [5]	1,335	---
	Changes to Existing Purchases [4]	(390)	(381)
	TOTALS =	5,557	4,931

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of year shown.
(3) Summer values are values for August of year shown.
(4) These are firm capacity and energy contracts with QF, Utilities and other purchases. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

III.C Issues Impacting FPL's Recent Planning Work

FPL's 2006 and early 2007 planning efforts have continued to address two issues that were identified in previous Site Plans as being items of on-going importance. Those two issues are: (1) the need to maintain fuel diversity in the FPL system and (2) the need to address the imbalance between regional load and generating capacity located in Southeast Florida.

1. System Fuel Diversity

FPL's plans to add the two advanced technology coal FGPP units by 2013 and 2014, respectively, is a key and integral part of FPL's plan to maintain fuel diversity on FPL's system. After these coal units come on-line, the role of natural gas in FPL's projected fuel mix will be no greater than 61% through 2016.

FPL has also begun the process to review the prospect for new nuclear generation and the advisability of initiating significant financial commitments in the face of schedule, cost, and regulatory uncertainties to do so. FPL will be taking necessary and appropriate steps in the near future to preserve new nuclear generation as an option for the latter half of the next decade in order to maintain and enhance fuel diversity in the FPL system.

FPL also has been involved in activities to investigate adding or maintaining renewable resources as a part of its generation supply. One of these activities is a variety of discussions with existing facilities aimed at maintaining or extending current agreements. In addition, and as a direct result of FPL's Sunshine Energy® Program, photovoltaic installations are being made. These include a 250 kw photovoltaic site in Sarasota County as well other smaller installations throughout FPL's service territory. Additionally, FPL is actively investigating a site for a demonstration wind generation project in the 10 MW range.

FPL maintains its interest in new and developing technologies, such as solar photovoltaic, solar thermal, and ocean current turbine technology. It is possible that renewable technologies may become more cost-effective over the next ten years and may be feasible additions to provide some diversity to the system fuel supply. FPL shares, with others, the objective of fostering the development and operation of additional cost-effective renewable sources of generation. Based upon available information, however, FPL does not believe that renewable resources are likely to contribute more than a modest amount to satisfying the annual electric load growth in FPL's territory.

In the future, FPL will continue to identify and evaluate alternatives that may maintain or enhance fuel diversity in its capacity resource mix including purchasing power from coal-fired facilities when such power becomes available. FPL also plans to maintain the ability to utilize fuel oil at those existing units that have that capability, although cost factors currently limit the expected use of these facilities.

2. Southeast Florida Imbalance

There currently is an imbalance between regionally installed generation and peak load in Southeast Florida. A significant amount of energy required in the Southeast Florida region during peak periods is provided through the transmission system from plants located outside the region. Based on the forecast for continued load growth in this region, the imbalance between generation and load is projected to increase unless additional generation capacity is periodically located within this region.

FPL's prior planning work concluded that either additional installed capacity in this region, or transmission capacity capable of delivering additional electricity from outside the region, would be required to address this imbalance.

Partly because of the lower transmission-related costs resulting from their location, Turkey Point Unit #5 and WCEC Units #1 and #2 were evaluated as the most cost-effective options to meet FPL's 2007 and 2009-2010 capacity needs, respectively. Adding Turkey Point Unit #5 and WCEC Units #1 and #2 will significantly reduce the imbalance between generation and load in Southeast Florida. Furthermore, the addition of the proposed FGPP units will also help address this imbalance by the addition of new transmission lines connecting Southeast Florida and the FGPP units.

Together these unit additions will help address the imbalance for at least much of the 2007-2016 reporting period addressed in this document. However, the Southeast Florida imbalance will remain a consideration in FPL's on-going resource planning work.

III.D Demand Side Management (DSM)

1. Currently Approved Programs and Goals:

FPL's currently approved DSM programs are summarized as follows:

Residential Conservation Service: This is an energy audit program designed to assist residential customers in understanding how to make their homes more energy-efficient through the installation of conservation measures/practices.

Residential Building Envelope: This program encourages the installation of energy-efficient ceiling insulation, reflective roofs, and roof membranes in residential dwellings that utilize whole-house electric air conditioning.

Duct System Testing and Repair: This program encourages demand and energy conservation through the identification of air leaks in whole-house air conditioning duct systems and by the repair of these leaks by qualified contractors.

Residential Air Conditioning: This is a program to encourage customers to purchase higher efficiency central cooling and heating equipment.

Residential Load Management (On-Call): This program offers load control of major appliances/household equipment to residential customers in exchange for monthly electric bill credits.

New Construction (BuildSmart): This program encourages the design and construction of energy-efficient homes that cost-effectively reduce coincident peak demand and energy consumption.

Residential Low Income Weatherization: This program addresses the needs of low-income housing retrofits by providing monetary incentives to various housing authorities, including weatherization agency providers (WAPS), non-weatherization agency providers (non-WAPS), and other providers approved by FPL. The incentives are used by these providers to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting.

Business Energy Evaluation: This program encourages energy efficiency in both new and existing businesses by identifying DSM opportunities and providing recommendations to business customers.

Business Heating, Ventilating and Air Conditioning: This program encourages the use of high-efficiency heating, ventilation, and air conditioning (HVAC) systems for business customers.

Business Efficient Lighting: This program encourages the installation of energy-efficient lighting measures for business customers.

Business Custom Incentive: This program encourages business customers to implement unique energy conservation measures or projects not covered by other FPL programs.

Commercial/Industrial Load Control: This program reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

Commercial Demand Reduction: This program, which started in 2002, is similar to the Commercial/Industrial Load Control program mentioned above in continuing the objective to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits.

Business Building Envelope: This program encourages the installation of energy-efficient building envelope measures, such as roof/ceiling insulation, reflective roof coatings, and window treatments for business customers.

Business On Call: This program offers load control of central air conditioning units to both small non–demand-billed and medium demand-billed business customers in exchange for monthly electric bill credits.

Business Water Heating: This program encourages the installation of energy-efficient water heating equipment such as heat pump water heaters and heat recovery units for business customers.

Business Refrigeration: This program encourages the installation of qualifying controls and equipment that reduce electric strip heater usage in refrigeration equipment for business customers.

FPL's approved DSM Goals for Summer MW reduction from these programs are presented in Table III.D.1.

Year	Goal Cumulative Summer MW
2005	74
2006	142
2007	212
2008	287
2009	366
2010	448
2011	532
2012	619
2013	708
2014	802

Table III.D.1: FPL's Summer MW Reduction Goals for DSM (At the Meter)

Table III.D.1 reflects FPL's DSM Goals for 2005–2014 as approved by the Florida Public Service Commission in June, 2004. These annual cumulative values assume a 1/1/05 starting point.

2. Research and Development

FPL continues to support research and development activities. Historically, FPL has performed extensive DSM research and development. FPL will continue such activities, not only through its Conservation Research and Development program, but also through individual research projects. These efforts will examine a wide variety of technologies that build on prior FPL research where applicable and will expand the research to new and promising technologies as they emerge.

Conservation Research and Development Program

FPL's Conservation Research and Development Program is designed to evaluate emerging conservation technologies to determine which are worthy of pursuing for program development and approval. FPL has researched a wide variety of technologies such as condenser coil cleaner and coating, ultraviolet lights for evaporator coils, Energy Recovery Ventilators (ERV), fuel cell demonstrations, CO_2 ventilation control, two-speed air handlers, and duct plenum repair. Many of the technologies examined have resulted in enhancements to existing programs or the development of new programs such as Residential New Construction, Commercial/Industrial Building Envelope, and Business On Call.

On Call Incentive Reduction Pilot

In March 2003, FPL received FPSC approval to perform a pilot for its On Call Program. Under the pilot FPL is offering to new participants a residential load control service similar to the On Call Program at a reduced incentive level. The offering of this pilot is allowing FPL to test its market research data and gauge whether FPL can repackage its current residential load control service, minimize customer attrition, achieve current goals for residential load control, and, ultimately, change On Call incentive levels without damaging FPL system reliability.

3. Additional DSM Contributions

Since FPL's current DSM Goals were established, FPL has continued to evaluate the potential for additional cost-effective DSM. Increases in FPL's forecasted peak growth, and the corresponding increase in projected resource needs, has resulted in FPL increasing its projection of cost-effective DSM by 564 MW at the generator from 2006-2015, and by another 120 MW at the generator in 2016. Therefore, FPL projects the implementation of an additional 684 MW at the generator of cost-effective DSM beyond FPL's DSM Goals.

III.E Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV bulk transmission lines that must be certified under the Transmission Line Siting Act.

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (KV)	(7) Capacity (MVA)
FPL	St. Johns (1)	Pringle	26	Dec-08	230	759
FPL	Manatee	BobWhite	30	Dec-11	230	1190
FPL	Grove Area (TBD)	Sweatt	25	Jun-12	230	759

(1) Final order certifying the corridor was issued on April 21, 2006.

Table III.E.1: List of Proposed Power Lines

In addition, there will be transmission facilities needed to connect several of FPL's committed and projected capacity additions to the system transmission grid. These transmission facilities for the committed capacity additions at the Turkey Point and the WCEC sites, plus for the projected capacity additions at the FGPP site, are described on the following pages. Because the projected combined cycle capacity addition for 2015 is as-yet unsited, no transmission facilities information is provided for this unit.

III.E.1 Transmission Facilities for Turkey Point Unit #5

The work required to connect Turkey Point Unit #5 in 2007 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four combustion turbines (CTs) and one steam turbine (ST).
2. Construct two string busses to connect the collector busses and main switchyard.
3. Add five main step-up transformers (4-225 MVA, 1-560 MVA), one for each CT and one for the ST.
4. Add a new two breaker bay to connect the collector bus at the Turkey Point switchyard.
5. Add a second two breaker bay at the Turkey Point switchyard to connect the other collector bus.
6. Add relays and other protective equipment.
7. Expand site and relay vault for two new line terminals at Turkey Point switchyard.

II. Transmission:

1. Upgrade the Turkey Point-Galloway Tap 230kV transmission line section to 1430 Amps.
2. Upgrade the Turkey Point–McGregor-Florida City 230kV transmission line section to 1495 Amps.
3. Upgrade the Turkey Point-Miller 230kV transmission line section to 1430 Amps.
4. Upgrade the Miller-Killian 230kV transmission line section to 1430 Amps.

III.E.2 Transmission Facilities for West County Energy Center (WCEC) Unit #1

The work required to connect West County Energy Center (WCEC) Unit #1 in 2009 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 4 breakers to connect the three CTs and one ST.
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 230 kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1-580 MVA), one for each CT and one for the ST.
4. Add a new Bay #4 with 3 breakers at the Corbett 230 kV main switchyard. Connect one string buss from the collector yard and relocate the Alva 230 kV terminal from Bay #3 to new Bay #4.
5. Connect second collector string buss to Bay #3.
6. Add relays and other protective equipment.
7. Breaker replacements:
   Corbett Sub – Replace eight (8) 230 kV breakers
   Ranch Sub – Replace five (5) 138 kV breakers
   Midway Sub – Replace one (1) 230 kV breaker
   Levee Sub – Replace one (1) 230 kV breaker
   Dade Sub – Replace two (2) 138 kV breakers

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.E.3 Transmission Facilities for West County Energy Center (WCEC) Unit #2

The work required to connect West County Energy Center (WCEC) Unit #2 in 2010 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 4 breakers to connect the three CTs, and one ST.
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 500kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA) one for each CT, and one for the ST.
4. At Corbett Sub, install one breaker and relocate Martin #2 500 kV line from Bay 2S to Bay 2N. Install one West County 500 kv string bus into Bay 2S.
5. At Corbett Sub, install one breaker and second West County 500 kV string bus into Bay 1S.
6. Add relays and other protective equipment.
7. Breaker replacements:
   Dade Sub – Replace one (1) 138 kV breaker
   Levee Sub – Replace four (4) 230 kV breakers
   Midway Sub – Replace three (3) 230 kV breakers
   Ranch Sub – Replace one (1) 230 kV breaker

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.E.4 Transmission Facilities for FGPP Unit #1

The work required to connect FGPP Unit #1 by 2013 with the FPL grid is projected to be as follows:

II. Substation:

1. Build new 500kV switchyard containing two bays with six breakers to connect the steam turbine and startup transformer.
2. Add two main step-up transformers (660 MVA each).
3. Build a new switching station with two 500kV bays, one 230kV bay, seven 500kV breakers and three 230kV breakers.
4. Add one 500/230kV, 750 MVA autotransformer bank.
5. Add relays and other protective equipment.

II. Transmission:

1. Build two 25 mile 500kV transmission lines connecting the switchyard to the switching station.
2. Build an additional 48 miles of 500kV transmission line to loop the existing Andytown-Orange River 500kV line into the new switching station.
3. Build an additional one mile of 230 kV transmission line to loop the Alva-Corbett 230 kV line into the new switching station.

III.E.5 Transmission Facilities for FGPP Unit #2

The work required to connect FGPP Unit #2 by 2014 with the FPL grid is projected to be as follows:

III. Substation:

1. Build new 500kV bay at the existing switchyard with 2 additional breakers to connect the coal unit and add a bus breaker to connect to connect the startup transformer.
2. Add two main step-up transformers (660 MVA each).
3. Build a new 500 kV bay at the existing switching station with two additional breakers to connect the new Levee 500 kV line
4. Andytown Substation – Remove the existing Levee #2 500 kV line terminal equipment
5. Add relays and other protective equipment.

II. Transmission:

1. Build an additional 74 miles of 500kV transmission line from the new switching station to Andytown 500kV station and disconnect the existing Andytown-Levee #2 500kV line from Andytown and connect to the new switching station.

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various technologies.

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970s in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities in Florida on both a daily and annual basis. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-Kilowatt (kW) system was placed into operation in 1984. (The system was removed in 1990 to make room for substation expansion after the testing of this PV installation was completed.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed below).

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was no longer projected to be cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980's, FPL introduced another renewable energy program, FPL's Passive Home Program. This program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for 6 passive homes with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test may be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

More recently, FPL has analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach does not require all of its customers to bear PV's high cost, but allows customers who are interested in facilitating the use of renewable energy the means to do so. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund that FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid. Thus, when sunlight is available, the PV-generated electricity displaces an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach for this program, which has been termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL began the effort in 1998 and received approximately $89,000 in contributions (that significantly exceeded the goal of $70,000). FPL purchased the PV modules and installed them at FPL's Martin Plant site.

FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was FPL's Photovoltaic Research, Development, and Education Project. This demonstration project's objectives were to: increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks (as well as the total annual energy capabilities of roof tile PV systems), and assess the homeowner's financial benefits and costs of PV roof tile systems. This project was completed in 2003.

The second effort initiated in 2000 was the Green Energy Project. The objectives of this Project were to: determine customer interest in an on–going renewable energy program, determine their price responsiveness and views on the different renewable technologies, and identify potential renewable energy supply sources that would meet the forecasted customer demand for this type of product. FPL conducted both customer research and issued a Request for Proposals (RFP) in 2001 to solicit proposals to potentially supply energy only from new renewable sources. This Project formed the basis for FPL's Green Power Pricing Research Project, and then led to FPL's Business Green Energy Research Project.

Both the Green Power Pricing Research Project and the Business Green Energy Research Project examined the feasibility of purchasing tradable renewable energy credits generated from new renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable sources. Customers who participate are charged higher premiums for purchasing the tradable renewable energy credits associated with electric energy generated by these sources.

Development of the Green Pricing Research Project was completed and filed with the FPSC in August 2003. As part of this process, a supply contract was put into place that allows FPL to match supply with demand for green energy. Tradable renewable energy credits are used to supply the renewable benefits required of this project. The FPSC approved the program on December 2, 2003 with program implementation during the first quarter of 2004. The project was marketed to customers as FPL's Sunshine Energy® program. As part of the project, FPL made a commitment that 150 kW of solar capacity would be put in place for every 10,000 program participants. The Business Green Energy Research Project focused on determining the interest and needs for business customers in this area. In 2006 FPL petitioned the FPSC for approval to make the Green Pricing Research Project a permanent program and expand eligibility to business customers. This approval was granted in the fourth quarter of 2006.

As of the end of 2006, FPL had 28,742 participants in the program. FPL has selected Rothenbach Park in Sarasota as the location to develop its first PV facility as a direct result of FPL's Sunshine Energy® renewable program. The 250 kilowatt FPL Solar Array at Rothenbach Park will be the largest solar facility in the state of Florida and one of the largest in the southeast.

The solar array will be mounted on the ground and will be visible from the road. The solar facility will be built with 1,200 photovoltaic solar panels and will be more than 28,000 square feet, about half the size of a football field. Each panel will be about 31 inches wide and 63 inches long. Construction on the new solar facility is scheduled to be completed in Summer 2007. FPL is currently investigating locations for additional solar sites when the next 150 kW PV commitment level in the Sunshine Energy® program is reached.

Several additional solar initiatives are currently under development. A residential community in the Naples/Ft Myers area is building 90 homes with 2 kW solar PV units on each home. A 2 kW demonstration site at the Miami Science Museum will be completed by 1st quarter 2007. In connection with SunSmart Schools, 2 kW PV systems are being installed in 4 schools by the end of March 2007. This activity is a continuation of previous FPL activities involving PV installations at schools. In 2003 as part of the State of Florida's PV for Schools program, FPL worked with three schools to install 4.8 kW PV systems. These schools were:

- A.D. Henderson Elementary & Middle School in Boca Raton
- Harlee Middle School in Bradenton
- Florida Gulf Coast University in Ft. Myers

FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy and as-available energy have been purchased by FPL from these developers. (Please refer to Tables I.B.1, I.B.2, and Table I.C.1). With recent legislative initiatives and new FPSC rules, FPL is seeing a renewed interest in the development of additional renewable energy projects and is actively working with developers on a number of potential projects.

Additionally, FPL is actively investigating a site for a demonstration wind generation project in Florida. FPL has conducted a survey of wind resources and is considering potential sites in both the Canaveral and Sarasota areas. The project size is estimated to be in the 10 MW range. FPL is also an active supporter of the recently established Center for Ocean Energy Engineering at Florida Atlantic University which aims to study the potential for ocean current energy conversion.

FPL has been investigating fuel cell technologies through monitoring of industry trends, discussions with manufacturers, and direct field trials. From 2002 through the end of 2005, FPL conducted field trials and demonstration projects of Proton Exchange Membrane (PEM) fuel cells with the objectives of serving customer end-uses while evaluating the technical performance, reliability, economics, and relative readiness of the PEM technology. The demonstration projects were conducted in partnership with customers and included 5 locations. The research projects were useful to FPL in identifying specific issues that can occur in field applications and the current commercial viability of this technology. FPL will continue to monitor the progress of these technologies and conduct additional field evaluations as significant developments in the fuel cell technologies occur.

In support of Florida Administrative Code Rule 25-6.065, Interconnection of Small Photovoltaic Systems, FPL works with customers to interconnect customer-owned PV systems. Through February 2007, 29 residential customer systems and 2 business customer systems have been interconnected. The total connect kW from these 31 systems is 108 kW. The residential customer average capacity per installation is 3.38 kW and the business customer average capacity per installation is 5.15 kW.

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980s, FPL relied primarily on a combination of fuel oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil–fired generation. In the early 1980s FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit #4 in 1989. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP.

The trend since the early 1990's has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective combined cycle generating units and the ready availability of natural gas. This planning document reflects an evolution in that trend in recognition that although efficient gas-fired generation continues to provide significant benefits to FPL's customers, adding natural gas-fired additions exclusively would, in the long term, create an unbalanced generation portfolio. FPL will add a new gas-fired CC unit in 2007 at Turkey Point and two new gas-fired CC units at the West County Energy Center in 2009 and 2010. These CC units will provide highly efficient generation that will benefit the entire FPL system by reducing transmission-related costs, mitigate the load-to-generation imbalance in Southeast Florida, and dramatically improve the overall system generation efficiency. However, FPL plans to complement these additions with two advanced technology coal units by 2013 and 2014, respectively. The addition of coal-fueled generation will maintain fuel supply diversity and assist in stabilizing fuel cost volatility through diversification.

FPL's future resource planning work will remain focused on identifying and evaluating alternatives that would maintain and/or enhance FPL's long-term fuel diversity. These fuel diverse alternatives may include: the purchase of power from new coal-based facilities, obtaining access to diversified sources of natural gas such as liquefied natural gas (LNG), preserving FPL's ability to utilize fuel oil at its existing units, and in the longer term, increased utilization of nuclear energy options. The evaluation of the feasibility and cost-effectiveness of these, and other possible alternatives, will be an ongoing part of future planning cycles.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2016 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

2. Fuel Price Forecasts

Fossil fuel price forecasts, and the resulting projected price differentials between fuels, are major drivers used in evaluating alternatives for meeting future generating capacity needs. FPL's forecasts are generally consistent with other published contemporary forecasts.

a) Fuel Price Forecast Methodology

Future oil and natural gas prices, and to a lesser extent, coal and petroleum coke prices, are inherently uncertain due to a significant number of unpredictable and uncontrollable drivers that influence the short- and long-term price of oil, natural gas, coal, and petroleum coke. These drivers include: (1) current and projected worldwide demand for crude oil and petroleum products; (2) current and projected worldwide refinery capacity/production; (3) expected worldwide economic growth, in particular in China and the other Pacific Rim countries; (4) Organization of Petroleum Exporting Countries (OPEC) production and the availability of spare OPEC production capacity and the assumed growth in spare OPEC production capacity; (5) non-OPEC production and expected growth in non-OPEC production; (6) the geopolitics of the Middle East, West Africa, the Former Soviet Union, Venezuela, etc., as well as, the uncertainty and impact upon worldwide energy consumption related to U. S. and worldwide environmental legislation, politics, etc.; (7) current and projected North American natural gas demand; (8) current and projected U.S., Canadian, and Mexican natural gas production; (9) the worldwide supply and demand for LNG; and (10) the growth in solid fuel generation on a U. S. and worldwide basis.

The inherent uncertainty and unpredictability in these factors today and tomorrow clearly underscores the need to develop a set of plausible oil, natural gas, and solid fuel (coal and petroleum coke) price scenarios that will bound a reasonable set of long-term price outcomes. In this light, FPL developed Low, Medium, and High price forecasts for oil, natural gas, and solid fuel, and a Shocked Medium (Shocked) price forecast for oil and natural gas which were used in the analyses of the FGPP advanced technology coal units.

FPL's Medium price forecast methodology is consistent for oil and natural gas. For oil and natural gas commodity prices, FPL's Medium price forecast applies the following methodology: (1) for 2006 through 2008, the methodology used the October 3, 2006 forward curve for New York Harbor 1% sulfur heavy oil, U. S. Gulf Coast 1% sulfur heavy oil, and Henry Hub natural gas commodity prices; (2) for the next two years (2009 and 2010), FPL used a 50/50 blend of the October 3, 2006 forward curve and monthly projections from The PIRA Energy Group; (3) for the 2011 through 2020 period, FPL used the annual projections from The PIRA Energy Group, and (4) for the period beyond 2020, recognizing that prices cannot increase indefinitely and that significantly high prices have created, and will continue to create, technological and economic opportunities for commodity substitution in the energy markets, FPL applied the annual rate of increase in the delivered price of solid fuel to the commodity cost of oil and natural gas. In addition to the development of oil and natural gas commodity prices, nominal price forecasts also were prepared for oil and natural gas transportation costs. The addition of commodity and transportation forecasts resulted in delivered price forecasts.

FPL's Medium price forecast methodology is also consistent for coal and petroleum coke prices. Coal and petroleum coke prices were based upon the following approach: (1) the price forecasts for Central Appalachian coal (CAPP), South American coal, and petroleum coke were provided by JD Energy; (2) the marine transportation rates from the loading port for coal and petroleum coke to an import terminal were also provided by JD Energy; (3) the Terminal Throughput Fee was based on a range of offers from comparable facilities throughout the Southeast U.S.; (4) the rail transportation rates from CAPP and from the import terminal facility to FGPP were based on the proposed rail transportation rates as of October 3, 2006. In order to achieve the maximum fuel supply diversity and delivery flexibility for FPL's customers, FPL assumed that the delivered price of solid fuel to the FGPP units would be a mix of 40% Central Appalachian coal, 40% South American coal, and 20% petroleum coke. The coal price forecast for FPL's existing coal plants at SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements.

The development of FPL's Low and High price forecasts for oil, natural gas, coal, and petroleum coke prices were based upon the historical relationship of prices realized by FPL's customers compared to the average for the 2000 through 2005 time frame. FPL developed these forecasts to account for the uncertainty which exists within each commodity as well as across commodities. These forecasts reflect a range of reasonable forecast outcomes.

The development of the Shocked Medium (Shocked) price forecast was based on the same methodology as the Low and High price forecasts described above. The shock was applied only to the oil and natural gas prices through 2016. In 2017, FPL averaged the Medium price forecast with the Shocked price forecast. From 2018 forward, all commodity prices are the same as in the Medium price forecast. FPL developed the Shocked price forecast as a sensitivity to show the impact of what a significant price increase in oil and natural gas could have on the evaluation of the FGPP advanced technology coal units.

FPL's four long-term oil, natural gas, coal, and petroleum coke price forecasts are reasonable and necessary for the analyses of the FGPP units. FPL's set of four fuel price forecasts bound the projected range of future forecast outcomes based on the actual range of prices realized by FPL's customers during the 2000 through 2005 period. During this period of time, all commodities showed significant variability, including periods of low and high prices, and periods of low and high price differentials between commodities, on both a domestic and worldwide basis.

Schedule 5
Fuel Requirements [1/]

		Actual 2/		Forecasted									
Fuel Requirements	Units	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016

1/ Reflects fuel requirements for FPL only.
2/ Source: A Schedules.

Note: As discussed on the preceding pages, FPL utilized four fuel cost forecasts in its 2006 and early 2007 resource planning work. The projected values shown on this form are based on one of these forecasts. For simplicity's sake, FPL is providing only one set of projected values in this document.

1/ Source: A Schedules
2/ The projected figures are based on estimated energy purchases from SJRPP and the Southern Companies.
3/ Represents a forecst of energy expected to be purchased from Qualifying Facilities, Independent Power Producers, net of Economy and other Power Sales.
4/ Net Energy For Load is also shown in Schedule 2.3.

Note: As discussed on the preceding pages, FPL utilized four fuel cost forecasts in its 2006 and early 2007 resource planning work. The projected values shown on this form are based on one of these forecasts. For simplicity's sake, FPL is providing only one set of projected values in this document.

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated. All values are Summer net MW.

2/ Total Capacity Available = Col.(2) + Col.(3) - Col.(4) + Col.(5).

3/ These forecasted values reflect the 2006 load forecast without DSM.

4/ The DSM MW shown represent cumulative load management capability plus incremental conservation from 1/2006-on for use with the 2006 load forecast. They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based.

5/ Margin (%) Before Maintenance = Col.(10) / Col.(9)

6/ Margin (%) After Maintenance = Col.(13) / Col.(9)

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Turkey Point Combined Cycle Unit # 5

(2) **Capacity**
a. Summer 1,144 MW
b. Winter 1,181 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2005
b. Commercial In-service date: 2007

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 11,000 Acres

(9) **Construction Status:** V Under Construction, more than 50% complete

(10) **Certification Status:** Certified

(11) **Status with Federal Agencies:** Certified

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2%	
Forced Outage Factor (FOF):	1%	
Equivalent Availability Factor (EAF):	97%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 97%	(First Base OperationYear)
Average Net Operating Heat Rate (ANOHR):	6,835	Btu/kWh (Base Operation)
Base Operation 75F,100%

Customer owned PV< 10 kw (est)	N/A	0.100	Unk	SUN	0.100	70.8	2002 - 2006
FPL Martin PV (est)	N/A	0.011	0.0	SUN	0.011	14.4	
FPL estimates there are 42,861 solar water heaters in our system				SUN			
FPL estimates there are 34,358 solar pool heaters in our system				SUN			

Notes
(1) Provide as much data available for facilities/resources "behind the meter" (as data permits).
(2) A 'Facility Name' may include an aggregated quantity (i.e., Pool Heaters, Solar-Powered Interstate Call Boxes, Photovoltaic Lighting, etc.).
(3) Self-Service MW and MWh pertains to power and energy consumed by the entity, whether it be a named facility or aggregated quantity.

(This page is left intentionally blank.)

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in FPL's service area is continuing, which heightens competition for air, land, and water resources that are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among utilities for its commitment to the environment. FPL's environmental leadership has been heralded by many outside organizations. In 2004, FPL Group earned a first place ranking among U.S. power companies and second globally in a report from the World Wildlife Fund for voluntary commitments to limit CO_2 emissions. This commitment was made to support initiatives to better manage utility impacts on climate change through use of greenhouse gas emission reductions and improvements in energy efficiency. The report stated that this was "primarily due to the company's leadership in developing wind energy and their commitment to dramatically improve their efficiency". In January 2007, FPL joined with a diverse group of U.S. based business market leaders and leading non-governmental organizations to form the U.S. Climate Action Partnership (USCAP) in recognition of the need for a national policy framework on climate change. USCAP has called upon the federal government to formulate mandatory economy-wide policies to reduce CO_2 emissions. As a further demonstration of FPL's efforts in sustainability, the EPA and the Department of Energy awarded FPL for its Sunshine Energy® program which allows customers who choose to participate to pay a premium for their electricity that is used to purchase tradable renewable energy credits associated with electric energy generated from renewable energy sources. FPL Group, the parent corporation of Florida Power & Light was also recently awarded its fourth number one rating of major electric utilities surveyed in an environmental assessment conducted by Innovest, an independent advisory group. This rating was in recognition of FPL Group's success in executing a strategy to become a clean energy provider harnessing primarily clean and renewable fuels while also boosting shareholder value. FPL Group was named one of the world's most Sustainable Corporations in Global 100 and was one of only two utilities to be so named in the United States.

FPL was awarded Edison Electric Institute's National Land Management Award for its stewardship of 25,000 acres surrounding its Turkey Point Plant. FPL won the Council for Sustainable Florida's award for its sea turtle conservation and education programs at its St. Lucie Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. FPL received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" for its emission-reducing "repowering" projects at its Fort Myers and Sanford Plants. Finally, FPL has been recognized by numerous federal and state agencies for its innovative endangered species programs which include such species as manatees, crocodiles, and sea turtles.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define its position. This statement reflects how FPL incorporates environmental values into all aspects of its activities and serves as a framework for new environmental initiatives throughout the company. FPL's Environmental Statement is:

It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:

- Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
- Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
- Encourage the wise use of energy to minimize the impact on the environment.
- Communicate effectively on environmental issues.
- Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident/emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with Corporate policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and Company policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2006 environmental outreach activities are noted in Table IV.E.1.

Table IV.E.1: 2006 FPL Environmental Outreach Activities

Activity	# of Participants
Visitors to Energy Encounter	20,000
Visitors to Manatee Park	150,000
Number of visits to FPL's Environmental Website	258,000
Number of pieces of Environmental literature distributed	>120,000

(All numbers are approximations.)

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified three Preferred Sites and eight Potential Sites for future generation additions. Preferred Sites are those locations where FPL has conducted significant reviews and taken action to site generation. Potential Sites are those sites that have attributes that support the siting of generation and are under consideration as a location for future generation. Some of these sites are currently in use as existing generation sites and some are not. The identification of a Potential Site does not indicate that FPL has made a definitive decision to pursue generation (or generation expansion in the case of an existing generation site) at that location, nor does this designation indicate that the size or technology of a generator has been determined. These Preferred Sites and Potential Sites are discussed in separate sections below.

IV.F.1 Preferred Sites

FPL identifies three Preferred Sites in this Site Plan: the existing Turkey Point plant site, the West County Energy Center (WCEC) adjacent to the existing Corbett FPL substation, and the FPL Glades Power Park (FGPP) located northwest of the city of Moore Haven in Glades County. The Turkey Point site is the location for a capacity addition that FPL will make in mid-2007. The West County Energy Center site is the location for capacity additions FPL will make in 2009 and 2010. The FGPP site is the projected location for advanced technology coal capacity additions by 2013 and 2014.

The capacity additions at the Turkey Point site and the WCEC site have been approved by the FPSC and by the Governor and Siting Board. FPL petitioned the FPSC for approval of the FGPP advanced technology coal units in January 2007. A decision is expected by the FPSC by July 2007.

The three Preferred Sites are discussed below.

Preferred Site # 1: Turkey Point Plant, Miami-Dade County

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear units and two conventional boiler, fossil units, the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the Everglades Mitigation Bank (EMB).

Units #1 and #2 are fossil fuel generating plants with approximate generating capacity of 400 MW each. Unit #1 was completed in 1967 and Unit #2 in 1968. Units #3 and #4 are nuclear generating units with approximate generating capacity of 700 MW each. Unit #3 was completed in 1972 and Unit #4 in 1973. Turkey Point also has five diesel peaking units that, in total, produce approximately 12 MW. These units are primarily used to provide emergency power, but occasionally run during the Summer to provide power during peak load demands.

The site for the new Turkey Point Unit #5, a "4-on-1" combined cycle electrical generating unit, is within the existing FPL Turkey Point facility property. The site is adjacent to the existing fossil Units #1 and #2, and includes the existing parking lot and storage areas immediately northwest of Units #1 and #2 as well as mangrove wetlands north of the facility.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Turkey Point plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the Turkey Point Unit #5 generating facility at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a self-contained cooling canal system that supplies water to condense steam used by the existing units' turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide and approximately four feet deep. The remaining developed area of the site is where the two fossil steam generating units and 5 diesel generators are located. South of, and adjacent to, the fossil plant are the two nuclear generating units. Further to the south, wetlands have been set aside as part of the Everglades Mitigation Bank (EMB) in an effort to restore these areas to historical plant communities and hydrological function.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the site was undeveloped dwarf red mangrove swamp that is tidally inundated with waters from Biscayne Bay. Along with the dominant red mangroves, buttonwood is a common canopy component, along with occasional white mangrove. Only a few individual black mangroves were observed within the site. Biscayne Bay is a shallow, subtropical bay supporting seagrasses, sponges, coral reefs, and a variety of marine life.

2. Listed Species

The construction and operation of Unit #5 is not expected to adversely affect any rare, endangered, or threatened species. Listed species known to occur in the nearby Biscayne National Park that could potentially utilize the site include the peregrine falcon (Falco peregrinus), wood stork (Mycteria americana), American crocodile (Crocodylus acutus), mangrove rivulus (Rivulus marmoratus), roseate spoonbill (Ajaja ajaja), limpkin (Aramus guarauna), little blue heron (Egretta caerulea), snowy egret (Egretta thula), American oystercatcher (Haematopus palliates), least tern (Sterna antillarum), brown pelican (Pelicanus occidentalis), the white ibis (Eudocimus albus), and bald eagle (Haliaeetus leucocephalus). No bald eagle nests are known to exist in the vicinity of the site. The federally listed, endangered American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American crocodile. A project-specific crocodile management plan was developed for construction of Unit #5.

3. **Natural Resources of Regional Significance Status**

Significant features in the vicinity on the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park, comprised of several miles of shoreline north of the Turkey Point facility extending offshore approximately 12 nautical miles. Biscayne National Park contains 180,000 acres, approximately 95% of which is open water interspersed with over 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant and is adjacent to the Miami-Dade County Homestead Bayfront Park which contains a marina and day use recreational facilities.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

Additional generating capacity is being added to the site for operation beginning in mid-2007. The new generating unit will consist of four new combustion turbines (CT) and four new heat recovery steam generators (HRSG) and a new steam turbine that will comprise Turkey Point Unit #5. Natural gas delivered via the existing pipeline is the primary fuel type for this unit (with ultra low sulfur light oil serving as a backup fuel).

Mitigation for unavoidable wetland impacts related to construction of Unit #5 includes: on-site hydrologic improvements to enhance existing wetlands, restoration and preservation of areas overgrown with exotic plant species, creation of an on-site lagoon, transfer of some mangrove-dominated lands to South Florida Water Management District and Biscayne National Park, and the purchase of mitigation credits from the EMB that is in the same drainage basin. The use of a cooling tower will minimize thermal discharges to the cooling canals. The facility already encompasses several preserved areas where wildlife is abundant.

g. Local Government future Land Use Designations

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. Site Selection Criteria Process

For the past several years, a number of FPL's existing power plant sites have been considered as potentially suitable sites for new or repowered generation. The Turkey Point plant has been selected as a Preferred site due to consideration of various factors including system load, an imbalance in the Southeast Florida region between load and generating capacity, and economics. Environmental issues are an important factor at this site and FPL will minimize environmental impacts and mitigate where impacts are unavoidable.

i. Water Resources

Unique to Turkey Point plant site is the self-contained cooling canal system that supplies water to condense steam used by the plant's turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide, and approximately four feet deep. The system performs the same function as a giant radiator. The water is circulated through the canals in a two-day journey, ending at the plant's intake pumps. During the slow journey down the canals, the water cools as much as 15 degrees

j. Geological Features of Site and Adjacent Areas

FPL's Turkey Point site is underlain by approximately 13,000 feet of sedimentary rock strata. The strata that extends to approximately 500 feet forms the Biscayne Aquifer. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily of marine origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The Tamiami formation is named for deposits composed principally of white cream-colored calcareous sandstone, sandy limestone, and beds and pockets of quartz sand. In the Turkey Point area, Key Largo limestone is present.

The Floridan Aquifer, located approximately 1,100 feet below the land surface, is a confined aquifer. The Floridan Aquifer system is composed entirely of carbonate rocks except for minor evaporates. The water in the carbonate rock aquifer is more highly mineralized.

k. Projected Water Quantities for Various

The additional quantity of water for industrial processing will be approximately 294 gallons per minute (gpm) for plant process and service water. Water for this type of use would be supplied by an existing county water system. A new water treatment plant is installed to provide treated water for the new unit. Cooling water for new Unit #5 will be processed through a cooling tower. FPL will use approximately 14 million gallons per day (mgd) of water from the Floridan Aquifer as the source of makeup water used by the cooling tower.

l. Water Supply Sources and Type

This additional capacity at the site will utilize the cooling tower for the dissipation of heat from the cooling water. A new water treatment system will be installed to provide treated water for Unit #5. The Floridan Aquifer will supply the makeup cooling water.

m. Water Conservation Strategies

The plant will implement a Water Conservation Plan including physical features, procedures, and employee training to conserve water resources. Features in the plant's water systems design will include, when practical:

- Automatic shutoff valves
- Use of flow restrictors
- Use of low volume sanitary facilities
- Low maintenance landscaping design

An awareness program will be implemented for employees that operate the plant. The awareness program will educate employees on water conservation methods, techniques, and procedures. Procedures will be reviewed on an annual basis with the first review occurring in approximately June 2008, one year after the expected commercial operation date. The Water Conservation Plan will be updated as necessary.

n. Water Discharges and Pollution Control

Heated water discharges are dissipated using the existing once-through cooling water system and the cooling canal system. Unit #5 cooling water will be processed through a cooling tower which will dissipate the heat prior to discharge to the cooling canal system. Storm water runoff is collected and used to recharge the surficial aquifer via a storm water management system. Design elements have been included to capture suspended sediments. Various facility permits mandate various sampling and testing activities that provide indication of any pollutant discharges.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by multiple fuel delivery facilities. There is currently a pipeline that supplies natural gas to the facility. The facility also has oil capabilities through on-site storage tanks and accessibility to barge deliveries. Unit #5 will utilize the existing pipeline with the addition of a compression system(s). An aboveground storage tank for the ultra-low sulfur light oil backup fuel will be added. The backup fuel for Unit #5 will be delivered to the site by truck.

p. Air Emissions and Control Systems

The use of natural gas and ultra-low sulfur light oil and combustion controls will minimize air emissions from this unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using the ultra-low sulfur light oil as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of Turkey Point Unit

#5 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. **Noise Emissions and Control Systems**

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise would be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will also be within allowable levels. Similar natural gas-fired facilities in Broward, Manatee, and Martin counties have been constructed and operated without exceeding allowable noise levels.

r. **Status of Applications**

FPL filed the Site Certification Application (SCA) for the Turkey Point Plant Unit #5 with the Florida Department of Environmental Protection (FDEP) on November 14, 2003, and received Site Certification by the Governor and Cabinet in February 2005. The U.S. Army Corps of Engineers issued a federal Dredge and Fill permit in February 2005. FDEP issued the Prevention of Significant Deterioration (PSD) air permit in February 2005. FPL acquired all permits and authorizations needed, and commenced construction in Spring 2005 with an anticipated, in-service date of mid-2007.

Preferred Site # 2: West County Energy Center, Palm Beach County

FPL has identified the property adjacent to the existing Corbett Substation property in unincorporated western Palm Beach County as a Preferred Site for the addition of new generating capacity. The site was selected for the addition of a new greenfield combined cycle natural gas power plant project with ultra-low sulfur oil as a backup fuel. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections. The proposed facility would use natural gas as the primary fuel and state-of-the-art combustion controls.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the West County Energy Center (WCEC) plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the WCEC generating facilities at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The land on the site is currently inactive but was previously dedicated to industrial and agricultural use. The site has been excavated, back-filled, and totally re-graded to an elevation approximately 10 ft. above surrounding land surface. No structures are present on the site and vegetation is virtually non-existent.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The plant site has been significantly altered by the construction and operation of a limestone mine where vegetation had been cleared and removed. The surrounding land use is predominantly sugar cane agriculture and limestone mining. FPL's existing Corbett substation is located north of the site. The Arthur R. Marshall Loxahatchee National Wildlife Refuge is located to the south of the proposed site.

2. Listed Species

Construction and operation of new units at the site is not expected to affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the mining activities. Common wading birds can be observed on areas adjacent to and occasionally within the property. The property is adjacent to areas that have been identified as potential habitat for wood stork.

3. Natural Resources of Regional Significance Status

The construction and operation of a gas-fired combined cycle generating facility at the proposed location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands including the Arthur R. Marshall Loxahatchee National Wildlife Refuge. It is not anticipated that construction will result in wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design option is to construct two new 1,200 MW (approximate) units each consisting of three new combustion turbines (CT) and three new heat recovery steam generators (HRSG) and a new steam turbine. These two new units are scheduled to be in-service in mid-2009 and mid-2010, respectively. Natural gas delivered via pipeline is the primary fuel type for this unit with ultra-low sulfur light oil serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the project site is "Rural Residential" according to the Palm Beach County Future Land Use Map. Designations for the area under the Palm Beach County Unified Land Development Code classified the project site and surrounding area as Special Agricultural District. The site has been granted conditional use for electrical power facilities under a General Industrial zoning district.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues.

i. **Water Resources**

Water from the Floridan Aquifer and surface water from the L10/L12 canal will be used for cooling, service, and process water. Water from the surficial aquifer will be treated and used for potable water.

j. **Geological Features of Site and Adjacent Areas**

The site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, clay, and phosphate grains. The deepest formation in Palm Beach County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Oldsmar formation. The published information on the sediments comprising the formations below the Avon Park Limestone is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach Counties.

k. <u>Projected Water Quantities for Various Uses</u>

The estimated quantity of water required for industrial processing for both units is approximately 450 gallons per minute (gpm) for uses such as process water and service water. Approximately 15 million gallons per day (mgd) in total of cooling water for the two generating units would be cycled through the addition of cooling towers. Water quantities needed for other uses such as potable water are estimated to be approximately 35,000 gallons per day (gpd).

l. <u>Water Supply Sources by Type</u>

The generating units will use available surface or ground water as the source of cooling water for the cooling towers. The cooling towers will also act as a heat sink for the facility process water. Such needs for cooling and process water will comply with the existing South Florida Water Management District (SFWMD) regulations for consumptive water use.

m. <u>Water Conservation Strategies Under Consideration</u>

Impacts on the surficial aquifer would be minimized and used only for potable water. Water from the Floridan Aquifer or the L10/L12 canal will be used for cooling purposes and cooling towers will be utilized. In addition, captured stormwater will be reused in the cooling tower whenever feasible. Stormwater captured in the stormwater ponds will also recharge the surficial aquifer.

n. <u>Water Discharges and Pollution Control</u>

Heat will be dissipated in the cooling towers. Blowdown water from the cooling towers, along with other wastestreams, will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. In addition, captured stormwater will be reused in the cooling towers whenever feasible The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is not located near an existing natural gas transmission pipeline that is capable of providing a sufficient quantity of gas. Upgrades of existing pipelines and/or lateral connections to other pipelines will be made for supply of natural gas. Ultra-low sulfur light fuel oil would be received by truck and stored in above-ground storage tanks to serve as backup fuel for the new units.

p. Air Emissions and Control Systems

The use of natural gas and ultra-low sulfur light fuel oil and combustion controls will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the West County Energy Center units will incorporate features that will make them among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will be within allowable levels.

r. Status of Applications

A Site Certification Application (SCA) for the construction and operation of the West County Energy Center project under the Florida Electrical Power Plant Siting Act was filed on April 14, 2005 and received Site Certification by the Governor and Cabinet on December 26, 2006. Palm Beach County Planning Zoning and Building department issued approval for the project on June 28, 2006. FDEP issued a Class I Underground Injection Control Exploratory Well permit on January 11, 2006 and a Class V Exploratory Well Permit on December 6, 2006. FDEP issued a Prevention of Significant Deterioration (PSD) air permit on January 10, 2007. After acquiring these permits and authorizations, FPL initiated construction in February 2007 and anticipates an in-service date for the first unit of mid-2009. An application for the final Underground Injection Control (UIC) system permit will be submitted once the exploratory well construction is completed.

Preferred Site # 3: FPL Glades Power Park (FGPP), Glades County

FPL has identified a 4,900 acre property in unincorporated Glades County as a Preferred Site for the addition of 1,960 MW of new generating capacity. The site boundary is located approximately 2.3 miles northwest of Moore Haven, Florida. The Preferred Site was selected for the addition of a new advanced technology coal project. The existing site is adjacent to a rail line that can be used for fuel delivery. In addition, the facility can be designed to beneficially use excess storm water from the region as one of the sources of cooling water. New transmission lines in Glades and Hendry Counties, as well as a new substation in Hendry County will be required to interconnect the facility to the FPL power grid. The proposed facility would use a combination of domestic coal and/or foreign coal with up to 20% petroleum coke. The proposed generation process is a highly efficient, ultra-supercritical pulverized coal technology. The facility will feature advanced, state-of-the-art pollution control equipment to minimize emissions.

a. U.S. Geological Survey (USGS) Map

A USGS map of the FPL Glades Power Park (FGPP) site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the proposed generating facilities at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The site is comprised of active sugar cane fields, pasture, and undeveloped land. Unpaved farm roads and irrigation ditches related to the sugar cane operations are also prevalent throughout much of the site. Land uses immediately surrounding the site are active sugar cane fields, open pasture, and undeveloped land.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The plant will be developed on approximately 4,000 acres of the 4,900 acre site, with the balance of the site being preserved. The area to be developed has been significantly altered by agricultural activities. Specifically, the natural topography, soils, and hydrology has been altered to create an area favorable for the production of sugar cane. Natural surface water drainage features have been modified through the construction of a network of irrigation ditches. The undeveloped portion of the site will be preserved.

Nicodemus Slough is located to the north of the site. Lake Okeechobee is located approximately 1.5 miles east of the site. The Fisheating Creek Wildlife Management Area is located approximately 4 miles north of the site.

2. Listed Species

Construction and operation of new units at the site is not expected to adversely affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the agricultural activities. The majority of the site is comprised of active sugar cane fields which are unsuitable habitat for most species due to the lack of native vegetation and the amount and frequency of human disturbance. However, wading birds and alligators do utilize the irrigation canals and opportunistic wildlife forage in areas of heavy machinery. Brazilian pepper/willow and marsh wetlands within the sugar can fields also provide habitat for avian species and common herpetofauna.

Three federally listed species have been observed at the site, including the wood stork, the crested caracara, and the Everglades snail kite. State-listed species observed at the site include the little blue heron, snowy egret, white ibis, tri-color heron, wood stork, sand hill crane, and American alligator. The site does not provide any critical wildlife habitat.

3. **Natural Resources of Regional Significance Status**

Construction and operation of the advanced technology coal generating facility at the proposed location is not expected to have adverse impacts on parks, recreation areas, or environmentally sensitive lands. Construction will impact approximately 300 acres of man-made irrigation/drainage ditches and 248 acres of low quality wetlands dominated by exotic vegetation. The irrigation/drainage ditches are vegetated by nuisance/exotic species of vegetation, receive agricultural runoff, and do not provide high quality aquatic habitat for fish and wildlife.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design option is to construct two new nominal 980 MW net advanced technology coal units with state-of-the-art pollution control equipment. These units are planned to be in-service no later than mid-2013 and mid-2014,respectively. Domestic and/or imported coal along with up to 20% petroleum coke delivered via rail is the fuel type for these units. The extensive array of pollution control equipment will make this one of the cleanest coal facilities in the U.S.

Proposed mitigation for unavoidable wetland impacts related to construction of the units includes will be accomplished through a combination of onsite freshwater marsh and forested wetland creation within the pasture portion of the site and preservation of the highest quality marsh, wet prairie, wetland scrub, and mature upland live oak/cabbage palm habitat at the site.

g. **Local Government Future Land Use Designations**

The site is located in unincorporated Glades County and is designated as Agricultural/Open on the Glades County Future Land Use Map.

The site is located in the Open Use Agriculture (OUA) zoning district. Power plants and ancillary facilities are listed as a permitted use in the Glades County Table of Zoning District Uses.

The use of the site for the plant and directly associated facilities is consistent with the existing land use plans and zoning ordinances.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site due to consideration of various factors including, but not limited to: site size, proximity to rail service, water resources, and environmental condition of the site (already disturbed).

i. **Water Resources**

A number of water sources are available for plant use at this location, including: recycled stormwater, Floridan Aquifer water, excess stormwater from the C-43/Caloosahatchee River, surficial aquifer water, and reclaimed water from the City of Moore Haven Publicly Owned Treatment Works (POTW).

j. **Geological Features of Site and Adjacent Areas**

The site is underlain by undifferentiated surficial sands and clays, Calooshatchee and Fort Thompson Formations, Tamiami Formation, and the Peace River Formation of the Hawthorne Group. Regionally, geologic features that are encountered within 1,000 feet of the land surface in Glades County include the Avon Park Formation, Ocala Group, Suwannee Limestone, Hawthorne Group, Tamiami, Caloosahatchee, and Fort Thompson Formations, and undifferentiated surficial sediments.

k. **Projected Water Quantities for Various Uses**

The total water requirement for the FGPP units is expected to average about 26 million gallons per day (mgpd) for process water, service water, and cooling water. The cooling water for the two proposed units would be cycled through the addition of mechanical draft cooling towers. Potable water will be provided by the City of Moore Haven and/or surficial aquifer wells.

l. **Water Supply Sources by Type**

The proposed units will use recycled stormwater, available surface or ground water, and reclaimed water as sources of cooling water for the cooling towers. The cooling towers will also act as a heat sink for the facility process water. Such needs for cooling and process water will comply with the existing South Florida Water Management District (SFWMD) regulations for consumptive water use.

m. Water Conservation Strategies Under Consideration

Impacts on the surficial aquifer would be minimized since it will only serve small water needs (i.e., service water). When available, excess stormwater will be used with the remainder of the water being obtained from the Floridan Aquifer for the source of cooling water. In addition, the entire plant site will capture and reuse stormwater and process water.

n. Water Discharges and Pollution Control

Heated water discharges will be dissipated in the cooling towers. Blowdown water from the cooling towers will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Industrial discharges will be minimized by treating and recycling equipment wash water, boiler blowdown water, and equipment area runoff. Storm water runoff will be collected and recycled in plant processes.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Fuel will be transported to the site by rail lines located adjacent to the site. The fuel will be transferred on site to a transfer tower where the fuel is unloaded into the active and inactive storage areas. The active storage area will maintain sufficient fuel for about 7 days of full operation by both units and the inactive storage area will maintain sufficient fuel for about 60 days of full operation by both units. The inactive storage area will be sealed.

The plant will produce recyclable byproducts that can be used in cement and wallboard manufacturing and other industries (fly ash, bottom ash, and synthetic gypsum). It is the intent to market all of these byproducts for beneficial reuse. However, as a contingency, the project will include construction of a synthetically lined byproduct storage area equipped with a leachate collection system where the byproducts can be routed in the event that market conditions do not enable recycling of some or all of the byproducts.

Only small quantities of other solid wastes will be generated by the FGPP units. These wastes will be managed in accordance with all local, state, and federal regulations.

p. **Air Emissions and Control Systems**

The use combustion controls and state-of-the-art pollution control equipment will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Combustion controls minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. Post-combustion NO_x emissions will be controlled using selective catalytic reduction (SCR). Emissions of SO_2 will be controlled using wet limestone flue gas desulfurization (FGD). Particulate matter will be controlled using a fabric filter (FF). A wet electrostatic precipitator (wet ESP) will be used to control fine particulates and sulfuric acid mist. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Further, each of these pollution controls will enhance or remove mercury. In addition, sorbent injection technology will be used to further enhance mercury removal. Taken together, the design of the FGPP units will incorporate features that will make them among the most efficient and cleanest coal-fired units in the State of Florida and the U.S.

q. **Noise Emissions and Control Systems**

A field survey and impact assessment of noise expected to be caused by construction activities at the site was conducted. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site during construction or operation of the facility.

r. **Status of Applications**

A Site Certification Application (SCA) for the construction and operation of the FPL Glades Power Park project under the Florida Electrical Power Plant Siting Act was filed on December 22, 2006. A Prevention of Significant Deterioration (PSD) permit application and an Underground Injection Control permit application were submitted to the Florida Department of Environmental Protection (FDEP) on December 19, 2006. A petition for approval of a Determination of Need for these units was filed with the FPSC on February 1, 2007 and a decision by the FPSC is expected by July 2007.

IV.F.2 Potential Sites for Generating Options

Eight (8) sites are currently identified as Potential Sites for near-term future generation additions to meet FPL's capacity needs.[3] These sites have been identified as Potential Sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these Potential Sites offer a range of considerations relative to engineering and/or costs associated with the construction and operation of feasible technologies. In addition, each Potential Site has different characteristics that will require further definition and attention. For the purpose of estimating water requirements for each site, it was assumed that either one dual-fuel (natural gas and light oil) simple cycle combustion turbine (CT) or a natural gas-fired combined cycle unit (CC) would be constructed at the Potential Sites. A simple cycle CT would require approximately 50 gallons per minute (gpm) for both process and cooling water (assuming air cooling). A CC unit would require approximately 150 gpm for service and process water and approximately 14 million gallons per day (mgd) for cooling water.

Permits are presently considered to be at least theoretically obtainable for all of these sites. No significant environmental constraints are currently known for any of these sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time FPL considers each site to be equally viable.

Potential Site # 1: Andytown Substation, Broward County

FPL has identified the Andytown Substation property in western unincorporated Broward County as a potential site for the addition of new generating capacity. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site has been included at the end of this chapter.

[3] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites.

b. **Land Uses**

The land uses for the potential site were designated as industrial or agricultural use.

c. **Environmental Features**

Extensive low-quality wetlands are adjacent to the site. Construction and operation of a new facility on this site would not be expected to adversely affect any rare, endangered, or threatened species.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Groundwater from the shallow aquifer or a local source of gray water have been identified as potential water sources. The Floridan Aquifer has also been identified as a potential cooling water source.

Potential Site # 2: Cape Canaveral Plant, Brevard County

This site is located on the FPL Cape Canaveral Plant property in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway (US 1). A rail line is located near the plant. The existing facility consists of two 400 MW (approximate) steam boiler type generating units.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. **Land Uses**

The land is primarily dedicated to industrial use; i.e., FPL's existing Cape Canaveral power plant Units #1 and #2. It is surrounded by grassy areas and a few acres of remnant pine forest. The land adjacent to the site is dedicated to light commercial and residential use.

c. **Environmental Features**

There are no significant environmental features on the site.

d. Water Quantities

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Existing on-site wells, reclaimed water, public supply water, and the existing once-through cooling water system are potential water supply sources.

Potential Site # 3: Desoto County Greenfield Site

This site is a "Greenfield" undeveloped site located on a 13,515 acre property in unincorporated Desoto County. The site is adjacent to portions of the Peace River and lies on both the east and west sides of US Hwy 17 approximately 3 to 5 miles north of the City of Arcadia. There are currently no facilities on the site.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site is found at the end of this chapter.

b. Land Uses

The land on the site is currently dedicated to agricultural use (sod farming, cattle grazing, and truck crops).

c. Environmental Features

Developed portions of the adjacent properties are primarily agricultural (sod farms, citrus groves, and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and a few small isolated wetlands.

d. Water Quantities

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Groundwater from the upper and lower Floridan Aquifer, or if available and practicable, a local source of gray water are potential water sources.

Potential Site # 4: Fort Myers Plant Site, Lee County

This site is located on FPL's existing 460-acre Fort Myers property. The existing facilities on the site include one 1,440 MW (approximate) combined cycle unit, 12 gas turbines, each with an approximate capacity of 54 MW, and 2 combustion turbines, each with an approximate capacity of 160 MW.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the Fort Myers plant site is found at the end of this chapter.

b. **Land Uses**

The land on the site is currently dedicated to industrial use with surrounding grassy and landscaped areas. Much of the site has been used in recent years for direct plant construction activities. The adjacent land uses include light commercial and retail to the east of the property, plus some residential areas located toward the west.

c. **Environmental Features**

Mixed scrub with some hardwoods can be found to the east and further south.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

The available water source is the Caloosahatchee River and the available groundwater source is the sandstone aquifer.

Potential Site # 5: Lauderdale Plant, Broward County

The Lauderdale site is located in Eastern Broward County approximately 5 miles inland from Dania Beach and less than 2 miles west of Ft. Lauderdale International Airport. The site is bounded on the south by Dania Cutoff Canal, the east by SW 30th Avenue, and the North by I-595.

The existing approximately 1,700 MW of generating capacity at FPL's Lauderdale site occupies a portion of the approximately 210 acres that are wholly owned by FPL. The generating capacity is made up of two combined cycle units (Units #4 and #5), and 24 simple cycle gas turbine (GT) units.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. **Land Uses**

The existing power plant facilities are located on approximately 130 acres. The existing site has been in use since the 1920s and is adjacent to a county resource recovery project.

c. **Environmental Features**

To the north of the power plant is an area of mixed uplands with a scattering of small wetlands.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Existing groundwater or the municipal water supply are potential water sources.

Potential Site # 6: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District (SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad.

The existing approximately 3,700 MW of generating capacity at FPL's Martin site occupies a portion of the approximately 11,300 acres that are wholly owned by FPL. The generating capacity is made up of two steam units (Units #1 and #2), plus three combined cycle units (Units #3, #4, and #8). The site includes a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

a. **U.S. Geological Survey (USGS) Map**

A USGS map for the site is found at the end of this chapter.

b. **Land Uses**

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres.

c. **Environmental Features**

To the east of the power plant there is an area of mixed pine flat wood with a scattering of small wetlands. To the north of the cooling pond there is a 1,200-acre area which has been set aside as a mitigation area. There is a peninsula of wetland forest on the West Side of the reservoir that is named the Barley Barber Swamp. The Barley Barber Swap encompasses 400 acres and is preserved as a natural area. There is also a 10-kilowatt (kW) photovoltaic energy facility at the south end of this site.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Surface water resources currently used at the Martin facility include the cooling pond which takes its water from the St. Lucie canal. The available ground water resource is the surficial aquifer system which is used as a source of potable and service water.

Potential Site # 7: Port Everglades Plant, Broward County

This site is located on the 94-acre FPL Port Everglades plant site in Port Everglades, Broward County. The site has convenient access to State Road (SR) 84 and I- 595. Rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (approximate) and two 400 MW (approximate) sized units. The four steam boilers are capable of firing residual fuel oil, natural gas, or a combination of both. The site also is home to twelve simple cycle gas turbine (GT) peaking units of 30 MW (approximate) each. The GT's are part of the Gas Turbine Power Park that is made up of 24 GT's at the Lauderdale Plant site and the twelve GTs at the Port Everglades site. The GT's are capable of firing either natural gas or liquid fuel.

a. U.S. Geological Survey (USGS) Map

A map of the site is found at the end of this chapter.

b. Land Uses

The land on this site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

c. Environmental Features

The shoreline of the intake and discharge canal banks are vegetated with fringing mangrove, with some open, maintained grass areas on the side.

d. Water Quantities

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Existing groundwater or the municipal water supply could be used for industrial process and makeup water. Industrial cooling water needs could be met using the existing one-through cooling water system. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

Potential Site # 8: Riviera Plant, Palm Beach County

This site is located on the FPL Riviera Plant property in Riviera Beach, Palm Beach County. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (approximate) steam boiler generating units and one retired 50 MW generating unit.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site is found at the end of this chapter.

b. Land Uses

The land on the site is primarily covered by the existing generation facilities. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development.

c. Environmental Features

The site is located on the Intra-coastal waterway near the Lake Worth Inlet which provides a warm water refugia for manatees during cold winter days. The plant property contains some open, maintained grass area.

d. Water Quantities

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

The existing municipal water supply could be used for industrial processing water. Industrial cooling water needs could be met using the existing once-through cooling water system. For once-through cooling water, FPL could use Lake Worth as a source of water. We believe these sources would provide sufficient water for either simple cycle or combined cycle generation.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance which is available to the FPL system and the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new units that may not adversely impact such limitations. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations and by evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system. Both site- and system-related transmission costs are developed for each different unit/unit location option or groups of options.

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's planned transmission facilities to interconnect and integrate FPL's resource plans and those that must be certified under the Transmission Line Siting Act are presented in Section III.E.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.[4]

In its 2006 reserve planning work, FPL utilized an updated load forecast. No sensitivity tests to this updated load forecast were utilized.

[4] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its fuel price forecasts are discussed in Chapter III of this document. FPL's 2006 resource planning work utilized four different fuel cost forecasts (and four different environmental compliance cost forecasts). A detailed discussion of these forecasts, and their impacts on the generation expansion plan, are presented in FPL's Petition To Determine Need for FPL's Glades Power Park Units #1 and #2 Electrical Power Plant filed February 1, 2007.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item #3, FPL used four fuel forecasts in the comparative economic analysis of clean coal generation. While these forecasts did not represent a constant cost differential between oil/gas and coal, four different costs differentials were represented in these forecasts.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 and Schedule 8 present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add over the planning horizon is presented on the Schedule 9 forms.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

The key financial assumptions used in FPL's most recent resource planning work were a 44.2% debt and 55.8% equity FPL capital structure, projected debt cost of 7.2%, and an equity return of 12.3%. These assumptions resulted in a weighted average cost of capital of 10.05% and an after-tax discount rate of 8.82%. FPL did not test the sensitivity of its resource plan to varying financial assumptions.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). As discussed in response to Discussion Item #2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective are identical when DSM levels are unchanged between competing plans. Therefore, in planning work in which DSM levels were unchanged, the equivalent cumulative present value of revenue requirements perspective was utilized.

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two system reliability criteria in its resource planning work. One of these is a minimum 20% Summer and Winter reserve margin. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the reliability standards established by the North American Electric Reliability Council (NERC) in its *Reliability Standards*. FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Reliability Standards* are available on the internet (http://www.nerc.com).

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Transmission Facility Rating Methodology* document that are also available on the internet (http://floasis.siemens-asp.com/OASIS/FPL/INFO.HTM).

The normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95/0.95	1.05/1.07
230	0.95/0.95	1.06/1.07
500	0.95/0.95	1.07/1.09

There may be isolated cases for which FPL may determine it prudent to deviate from the general criteria stated above. The overall potential impact on customers and the probability of an outage actually occurring, as well as other factors, would influence the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption is revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. Finally, FPL is careful to claim only program savings for the average life of the installed efficiency measure. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

Among the strategic factors FPL typically considers when choosing between resource options are the following: (1) fuel diversity; (2) technology risk; (3) environmental risk, and (4) site feasibility. The consideration of these factors may include both economic and non-economic aspects.

Fuel diversity relates to two concepts, the diversity of sources of fuel (e.g., coal vs. oil vs. natural gas), and the diversity of supply for a single fuel source (for example alternative pipeline suppliers for natural gas). All other factors being equal, supply options that increase diversity in fuel source and/or supply would be favored over those that do not.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts on the FPL system, including environmental compliance costs. Technologies regarded as more acceptable from an environmental perspective for a plan are those which minimize environmental impacts through highly efficient fuel use and state of the art controls (e.g., advanced technology coal technologies versus conventional pulverized coal).

Site feasibility assesses a wide range of economic, regulatory, and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed, elements of FPL's capacity additions include the construction of new generating capacity at an existing site; Turkey Point and at a new site; West County Energy Center. These generation construction projects were selected after evaluating competing bids received in response to Requests for Proposals (RFP) issued by FPL. The FPSC subsequently approved FPL's decision to construct these new combined cycle units in Determination of Need dockets.

In 2006 FPL sought, and was granted by the FPSC, a waiver from the RFP requirement of the Bid Rule in order to seek approval for advanced technology coal generation as early as possible. FPL filed its Need petition for two advanced technology coal units with the FPSC on February 1, 2007.

The construction capacity addition decisions projected in this document for 2015 and beyond are expected to be conducted in a manner consistent with the Commission's Bid Rule.

Identification of self-build options beyond those units already approved by the FPSC and Governor and Siting Board, or units for which FPL is currently seeking approval, in FPL's Site Plan is not an indication that FPL has pre-judged any capacity solicitation it may conduct. The identification of future capacity units is required of FPL and represents those alternatives that appear to be FPL's best, most cost-effective self-build options at this time. FPL reserves the right to refine its planning analyses and to identify other self-build options. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an RFP is issued for supply-side resources, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

---

(1) FPL has identified the need for a new 230kV transmission line (by December 2008) that requires certification under the Transmission Line Siting Act. The new line will connect FPL's St. Johns Substation to FPL's proposed Pringle Substation (also shown on Table III.E.1). The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

(2) FPL has identified the need for a new 230kV transmission line (by December 2011) that requires certification under the Transmission Line Siting Act. The new line will connect FPL's Manatee Substation to FPL's proposed BobWhite Substation (also shown on Table III.E.1). The construction of this line is necessary to serve existing and future customers in the Manatee and Sarasota areas in a reliable and effective manner.

(3) Additionally, FPL has identified the need for a new 230kV transmission line (by June 2012) that requires certification under the Transmission Line Siting Act. The new line will connect a future FPL substation in the Grove Area (TBD) to FPL's Sweatt Substation (also shown on Table III.E.1). The construction of this line is necessary to serve existing and future customers in the Okeechobee and St. Lucie areas in a reliable and effective manner.

Re: 2008 – 2017 Ten Year Site Plan

Dear Ms. Cole:

In accordance with Chapter 186 (Section 186.801 – Ten Year Plans) of the Florida Statues, enclosed for filing are twenty-five (25) copies of Florida Power & Light Company's 2008 – 2017 Ten Year Power Plant Site Plan.

If you have any questions, please do not hesitate to contact me.

Sincerely,

Sabrina Spradley

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (F.A.C.).

This Ten Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2007 and that were on-going in the first quarter of 2008. The forecasted information presented in this plan addresses the 2008–2017 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten-year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings, at the appropriate time.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, based on FPL's IRP work in 2007 and

early 2008.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as preferred and potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve “discussion items” which pertain to additional information that is to be included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2008 Ten Year Power Plant Site Plan (Site Plan) presents FPL's current plans to increase its electric generation capability (owned or purchased) as part of its efforts to meet its projected incremental resource needs for the 2008-2017 time period. By design, the primary focus of this document is on supply side additions; i.e., electric generation capability. The supply side additions discussed in this document are resources projected to be needed after accounting for FPL's extensive demand side management (DSM) additions.

The resource plan that is presented in FPL's 2008 Site Plan contains some similarities to the resource plan presented in FPL's 2007 Site Plan, especially for the early years of the ten-year period. However, there are also some significant changes in the current resource plan.

I. Similarities to the Resource Plan Presented in the 2007 Site Plan:

There are two key similarities in the current resource plan presented in this document compared to the resource plan presented in the 2007 Site Plan. One similarity is the addition of new generating units in 2009 and 2010. In each of these years, FPL will be adding one 1,219 MW (Summer) combined cycle (CC) unit in western Palm Beach County. The site for these units is named the West County Energy Center (WCEC) and these units are identified as West County Energy Center Units 1 and 2 (WCEC 1 and 2). Both of these CC units were approved by the Florida Public Service Commission (FPSC) in June 2006. FPL's applications for site certification for these units under the Florida Electric Power Plant Siting Act were approved by the Governor and the Cabinet serving as the Siting Board in December 2006.

The other key similarity to the resource plan presented in the 2007 Site Plan is FPL's continuing significant efforts to implement cost-effective demand side management (DSM). These efforts include meeting FPL's approved DSM Goals through 2014, implementing additional cost-effective DSM through 2014 that was identified by FPL after the DSM Goals were established, and a projection of continued DSM additions in 2015 through 2017 at an annual implementation rate commensurate with that in the years leading up to 2014. These DSM efforts are projected to add approximately 1,539 MW of cost-effective DSM from August 2006 through August 2017. These 1,539 MW of additional DSM will avoid the need for approximately 1,847 MW of additional generating capacity that otherwise would be needed to continue to meet FPL's 20% reserve margin planning criterion. Through these DSM efforts FPL will continue to build upon its industry-leading position in both energy efficiency DSM programs and overall DSM achievement, as reported annually by the U.S. Department of Energy.

II. Changes From the Resource Plan Presented in the 2007 Site Plan:

There are three primary factors that caused FPL to change its resource plan from the one presented in the 2007 Site Plan. These three factors, and the changes in the resource plan that result from these factors, are briefly described below and are addressed in more detail in Chapters II and III of this document.

The first factor that is driving changes in the current resource plan is FPL's new load forecast. FPL now projects a lower rate of population growth than forecasted in the 2007 Site Plan for the next several years. However, FPL's current load forecast also reflects its plan to serve a portion of the load and energy requirements of Lee County Electric Co-Operative (Lee County) starting in 2010, and to serve the full load and energy requirements of Lee County starting in 2014. FPL's current projection of peak loads compared to that presented in the 2007 Site Plan is for lower peaks through 2013, but higher peaks for 2014 through 2017.

Although the timing of growth in peak load has changed, significant growth in both peaks and annual energy is still projected through 2017 and this growth will necessitate significant increases in generating capacity. In addition, because of the slower growth in peak load projected for the earlier years, FPL will have an opportunity to consider upgrades to its existing generating units, including the possible repowering of one or more units.

The second factor is that new advanced coal technology power plants are no longer seen as viable options in Florida over the ten-year reporting period for this Site Plan. Concerns over greenhouse gas emissions have resulted in advanced technology coal power plants being removed from FPL's list of generation options currently under consideration. The primary consequence is that the only type of generating unit that can be considered as a large-scale resource option to meet the growing needs of FPL's customers in the ten year reporting period is a natural gas-fired combined cycle unit.

The third factor that is driving change in FPL's resource plan is the Executive Orders issued by Florida's Governor Crist in July 2007 that, in part, called for a significant reduction in greenhouse gas emissions in Florida and for an increase in the amount of energy provided by renewable, non-emitting sources. The consequence of this factor is to reinforce FPL's on-going efforts to increase the production of electricity from nuclear energy and renewable energy options in the future, and to seek to increase the efficiency of its non-nuclear generating units.

The development of the resource plan presented in this document has taken these three factors, and other concerns, into account. As a result, the current resource plan has changed from the resource plan presented in the 2007 Site Plan in the following ways:

- **Increased Nuclear Generating Capacity:** On January 7, 2008, the Florida Public Service Commission approved FPL's request to uprate, by 414 MW, the generating capacity of FPL's four existing nuclear generating units – Turkey Point Nuclear Units 3 & 4 and St. Lucie Nuclear Units 1 & 2. The capacity of each unit will increase between 103 or 104 MW. The in-service dates for the uprates are: December 2011 for St. Lucie 1, May 2012 for Turkey Point 3, June 2012 for St. Lucie 2, and December 2012 for Turkey Point 4. In addition, although not specifically presented in this document due to the fact that the reporting period ends in 2017, FPL has filed with the FPSC for a Determination of Need for two new nuclear units at its existing Turkey Point power plant site. One of these units is projected to come in-service in 2018 and the other is projected to come in-service in 2020. The FPSC voted to approve the need for these two new nuclear units on March 18, 2008 and the FPSC is expected to issue the final order by mid-April 2008. Increased nuclear capacity is projected to result in economic savings to FPL's customers while making significant contributions to both greater system fuel diversity and lower greenhouse gas emissions.

- **Increased Renewable Energy Contribution:** FPL issued a renewable energy-only Request for Proposals (RFP) in 2007 and will be issuing another one in April 2008. FPL is also directly pursuing renewable energy through several other efforts. FPL's plans include building a wind energy generation facility totaling up to approximately 13.8 MW at FPL's existing St. Lucie nuclear power plant site. The wind energy facility is expected to go in-service starting in 2009. In addition, several FPL solar thermal and/or photovoltaic (PV) facilities are being evaluated that could go in-service in the 2009 – 2012 time frame. FPL is also currently assuming, for planning purposes, that contract extensions and/or new contracts will be reached with several existing renewable energy suppliers whose contracts with FPL are set to expire within this ten-year period. In addition, FPL's resource plan reflects its intent to obtain additional capacity and/or energy from the Renewable RFP solicitations or its own renewable energy development efforts.

For purposes of this planning document, FPL is assuming that 269 MW of firm capacity from renewable facilities will be added to FPL's system in the ten-year reporting period. It is currently assumed that other renewable energy additions will likely be added and that these additions would serve FPL's customers as intermittent, as-available energy resources, not as resources that provide firm capacity. As actual operating data at system peak hours for these renewable energy facilities becomes available, the potential of these renewable facilities to provide firm capacity will be better known. Any cost-effective renewable resources that FPL can add to its system will help FPL increase fuel diversity and reduce greenhouse gas emissions.

- **2011 Addition of WCEC 3:** FPL issued a capacity Request for Proposals (RFP) in December 2007 that solicited firm capacity proposals with in-service dates in the June 2011 to June 2012 time frame. A total of 3 proposals were received in response to the RFP. These proposals have been compared to FPL's next planned generating unit, a three-on-one combined cycle unit at the West County Energy Center (WCEC) site that is identical in technology and size to the WCEC 1 & 2 units. After an evaluation of these options by FPL and an Independent Evaluator, the WCEC 3 unit, proposed to be placed in-service in June 2011, was selected as the best option for FPL and its customers. FPL plans to submit a petition to the FPSC in April 2008 for approval of a Determination of Need for WCEC 3. Not only will the addition of WCEC 3 in 2011 result in significant economic savings to FPL's customers, its addition in June of 2011 also provides an opportunity for FPL to consider repowering one or more of its existing plants.

In fact, adding WCEC 3 in 2011 is necessary for FPL to have the option of repowering one or more of its existing plants by 2013 or 2014 in place of adding new generation at a "greenfield" site in that timeframe. Repowering could effectively transform as much as approximately 1,400 MW of relatively inefficient, existing steam generation into 2,438 MW of new, highly efficient, state-of-the-art, environmentally benign advanced combined cycle units. It is anticipated that such repowerings would result in economic savings to FPL's customers and reduced system emissions, including CO_2 emissions. As a result, repowering these plants by 2013 or 2014 could enable FPL to comply with the 2017 CO_2 emission targets proposed in 2007 by Governor Crist. FPL has initiated a thorough evaluation of this repowering alternative to determine its costs and quantify its benefits relative to those of other alternatives before it can make a decision to proceed with repowering. However, because repowering existing plants would initially require removal of approximately 1,400 MW of existing generating capacity from service in 2011, it is necessary to add WCEC 3 in 2011 to offset the loss of existing capacity and maintain a 20% reserve margin, thereby preserving the repowering option.

Finally, for long-term planning purposes, this document shows unsited combined cycle units similar in technology and design to those being added at the WCEC site being added to meet capacity needs for 2014 through 2017. However, no decision regarding these capacity options needs to be made, or has been made, at this time.[1]

As previously mentioned, the reduction of greenhouse gas emissions, particularly carbon dioxide (CO_2), has become a major factor in FPL's resource planning work. FPL already has a relatively low CO_2 emission rate (CO_2 tons per MWh generated) compared to other utilities due to its four existing nuclear units, the high efficiency of its combined cycle generating units, a number of renewable capacity and energy contracts, and its strong on-going DSM efforts. In addition, changes in FPL's 2008 resource plan, compared to that presented in its 2007 Site Plan, will result in a further lowering of FPL's CO_2 emission rate. Specifically, the nuclear capacity uprates, the addition of new, highly efficient combined cycle units, potential renewable resource additions, and significant on-going DSM efforts are projected to not only lower FPL's CO_2 emission rate, but also temporarily lower FPL's total annual CO_2 emissions.

However, despite this reduction in FPL's system CO_2 emission rate, significant load growth driven primarily by projected increases in population will cause total annual CO_2 emissions to increase at least until the two proposed new nuclear units at Turkey Point come in-service in 2018 and 2020, respectively.

As previously mentioned, FPL's peak load is projected to continue to increase at a still significant pace over the ten-year period. At present, FPL projects that it will need 3,625 MW of additional capacity through 2017 after the proposed addition of WCEC 3. Consequently, FPL's total generation capability is projected to significantly increase during the 2008-2017 time period as shown in Table ES.1. The table reflects FPL's current planned changes to existing generation units (due to scheduled unit overhauls, etc.), projected changes in the delivered amounts of purchased power, assumed capacity increases from certain renewable facilities, the capacity uprates of its existing nuclear units, and the planned additions of new generating units. Note that this table focuses solely on changes in capacity purchases and generating units. As such, it does

[1] Repowering at existing FPL sites remains an alternative to construction at new sites and FPL will continue to examine this option. In addition, both other generating options and DSM options will continue to be evaluated. FPL will be filing for approval of new DSM Goals in 2009 that will address DSM for the time frame of 2010 through 2019.

not directly address FPL's significant DSM efforts, but these DSM contributions have been incorporated prior to making a projection of new generating unit additions. Likewise, because FPL will be projecting the contribution of a number of new renewable resources as non-firm, energy-only resources at least until actual operating data at the facilities' specific sites are available, a number of the new renewable resources currently being considered, as discussed above and in Chapter III, are not included in Table ES.1.

FPL's ongoing resource planning efforts will continue to be influenced by the three driving factors discussed above (i.e., a new load forecast, advanced coal technology no longer being a viable option, and the Governor's Executive Orders)and by several other items FPL refers to as system concerns. These system concerns include: (1) maintaining/enhancing fuel diversity in the FPL system and (2) maintaining a balance between load and generating capacity in Southeastern Florida. In addition, FPL's resource planning work will seek opportunities to further enhance the operating efficiency of its existing generation fleet.

Table ES.1: Projected Capacity Changes and Reserve Margins for FPL

Projected Capacity Changes and Reserve Margins for FPL (1)		Net Capacity Changes (MW)		FPL Reserve Margin (%)	
		Winter (2)	Summer (3)	Winter	Summer
2008	Changes to Existing Units	41	14	28.4%	23.0%
	Changes to Existing Purchases (4)	(836)	---		
2009	West County Unit #1 (5)	---	1,219	25.0%	24.9%
	Changes to Existing Units	28	1		
	Changes to Existing Purchases (4)	(326)	(431)		
2010	West County Unit #1 (5)	1,335	---	25.4%	25.2%
	West County Unit #2 (5)	---	1,219		
	Extension Renewable Capacity Purchases	98	98		
	Changes to Existing Purchases (4)	(559)	(455)		
2011	West County Unit #2 (5)	1,335	---	28.9%	27.9%
	West County Unit # 3 (5)	---	1,219		
	New Renewable Capacity Purchases	---	32		
	Extension Renewable Capacity Purchases	45	45		
	Changes to Existing Purchases (4)	(46)	(45)		
2012	Changes to Existing Purchases (4)	---	(156)	33.3%	26.0%
	West County Unit # 3 (5)	1,335	---		
	New Renewable Capacity Purchases	126	94		
	Changes to Existing Nuclear Units	103	310		
2013	Changes to Existing Nuclear Units	311	104	31.5%	24.0%
	Changes to Existing Purchases (4)	(180)	---		
2014	Unsited 3 x 1 CC #1 (5)	---	1,219	24.7%	23.8%
2015	Unsited 3 x 1 CC #1 (5)	1,335	---	27.1%	21.1%
2016	Unsited 3x1 CC # 2 (5)	---	1,219	20.2%	22.9%
	Unsited 3x1 CC # 3 (5)	---	1,219		
	Changes to Existing Purchases (4)	(930)	(1,311)		
2017	Unsited 3x1 CC # 2 (5)	1,335	---	25.9%	20.1%
	Unsited 3x1 CC # 3 (5)	1,335	---		
	Changes to Existing Purchases (4)	(390)	---		
	TOTALS =	5,495	5,614		

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of year shown.
(3) Summer values are values for August of year shown.
(4) These are firm capacity and energy contracts with QF, Utilities and other purchases. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.7 million people. FPL served an average of 4,496,589 customer accounts in thirty-five counties during 2007. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management (DSM), and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, Florida. The current generating facilities consist of four nuclear units, three coal units, twelve combined cycle units, seventeen fossil steam units, forty eight combustion gas turbines, one simple cycle combustion turbine, and five diesel units. The location of these ninety generating units is shown on Figure I.A.1 and in Table I.A.1.

FPL's bulk transmission system is comprised of 6,640 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 573 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

FPL Generating Resources by Location

I.B Firm Capacity Power Purchases

Purchases from Qualifying Facilities (QF):

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five qualifying facilities; i.e., cogeneration/small power production facilities, to purchase firm capacity and energy.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Purchases from Utilities:

FPL has a Unit Power Sales (UPS) contract to purchase 931 MW, with a minimum of 381 MW, of coal-fired generation from the Southern Company (Southern) through May 2010. An additional contract with Southern will result in FPL receiving 930 MW from June 2010 through the end of December 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 381 MW (Summer) and 390 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. Due to Internal Revenue Service (IRS) regulations, the total amount of energy that FPL may receive from this purchase is limited. FPL currently assumes, for planning purposes, that this limit will be reached at the end of April 2016. (FPL also has ownership interest in these units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.)

Other Purchases:

FPL has other firm capacity purchase contracts with a variety of Non-QF suppliers. These purchases are generally near-term in nature. Table I.B.1 and I.B.2 present the Summer and Winter MW, respectively, resulting from all firm purchased power contracts discussed above through the year 2017. For planning purposes, FPL assumes an additional 269 MW of firm capacity will be supplied from renewable energy sources. This firm capacity is expected to be provided through a variety of sources including: contract extensions and/or new contracts with existing renewable facilities currently under contract with FPL but whose contracts are set to expire in 2009 – 2010, proposals received in response to a new Renewable RFP that FPL plans to issue in April 2008, and/or FPL's own renewable development efforts.

Table I.B.1: FPL's Firm Purchased Power Summer MW

Summary of FPL's Firm Capacity Purchases: Summer MW (for August of Year Shown)

I. Purchases from QF's:

Cogeneration Small Power Production Facilities	Contract Start Date	Contract End Date	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017

I.C Non-Firm (As Available) Energy Purchases

FPL purchases non-firm (as-available) energy from several cogeneration and small power production facilities. Table I.C.1 shows the amount of energy purchased in 2007 from these facilities.

Table I.C.1: As Available Energy Purchases From Non-Utility Generators in 2007

Project	*County*	*Fuel*	*In-Service Date*	*Energy (MWH) Delivered to FPL in 2007*
Tropicana	Manatee	Natural Gas	2/90	19,067
Elliot	Palm Beach	Natural Gas	7/05	297
US Sugar-Bryant	Palm Beach	Bagassee	2/80	1,432
Okeelanta	Palm Beach	Bagassee/Wood	11/95	265,475
Georgia Pacific	Putnam	Paper by-product	2/94	3,415
Tomoka Farms	Volusia	Landfill Gas	7/98	20,500
Rothenbach Park	Sarasota	PV	10/07	48
Customer Owned PV	Various	PV	Various	60

I.D. Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include a number of conservation/energy-efficiency and load management initiatives. FPL's DSM efforts through 2007 have resulted in a cumulative Summer peak reduction of approximately 3,958 MW at the generator and an estimated cumulative energy saving of approximately 42,301 Gigawatt Hour (GWh) at the generator. After accounting for reserve margin requirements, FPL's DSM efforts through 2007 have eliminated the need to construct the equivalent of approximately 12 new 400 MW generating units.

Table I.D.1 presents FPL's DSM projections. This projection captures: FPL's DSM Goals approved by the Florida Public Service Commission through 2014, additional cost-effective DSM identified by FPL after the DSM Goals were established, and a projection of continued DSM implementation for 2015 – 2017 at an implementation rate commensurate with the projected annual rate of implementation for the years immediately preceding 2014.

Table I.D.1. : FPL's DSM Goals and Additional DSM: 2006 – 2017 (Summer MW)

Projected Incremental FPL DSM: 2006 - 2017

Year	DSM Projected by FPL (Summer MW at Generator) (1)
2006	1,491
2007	1,768
2008	1,908
2009	2,034
2010	2,146
2011	2,264
2012	2,388
2013	2,516
2014	2,651
2015	2,790
2016	2,910
2017	3,030
Incremental DSM MW from 2006 through 2017 =	1,539

Notes: (1) The DSM Summer MW shown are from column (8) in Schedule 7.1 and reflect projected DSM signups from 8/2006 through 8/2020. These values reflect FPL's DSM Goals through 2014 plus additional DSM through 2015 identified as cost-effective after the DSM Goals were established. These values also include a projected continuation of DSM signups for 2015 - 2017.

Total System as of December 31, 2007 =												**23,494**	**22,135**

1/ These ratings are peak capability.
2/ These ratings represent Florida Power & Light Company's share of Scherer Unit No. 4, adjusted for transmission losses.
3/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Unit No. 1 and No. 2, excluding Jacksonville Electric Authority (JEA) share of 80%.
4/ Total capability of each unit is 853/839 MW. FPL's ownership share of St. Lucie 1 and 2 is 100%(853/839) and 85% (714/726) respectively as shown above. FPL's share of the deliverable capacity from each unit is approx. 92.5% and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

II. A. Overview of the Load Forecasting Process

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are typically developed on an annual basis for resource planning work at FPL and new forecasts were developed by FPL in February 2008. These forecasts are a key input to the models used to develop FPL's Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

Consistent with past forecasts, the primary drivers to develop these forecasts are demographic trends, weather, economic conditions, and prices of electricity. In addition, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from the National Oceanic and Atmospheric Administration (NOAA), and inputs from FPL's own customer service planning areas. In the area of demographics, population trends, plus housing characteristics such as housing starts, housing sizes, and vintage of homes, are assessed.

The projections for the national and Florida economies are obtained from Global Insight. Population projections are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects FPL's energy sales and peak demand. Two sets of weather variables are developed and used in FPL's forecasting models:

1. Cooling and Heating Degree-Hours are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Hours are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. A composite temperature hourly profile is derived using hourly temperatures across FPL's service territory. Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained. In developing the composite hourly profile these regional temperatures are weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Hours which are based, respectively, on starting point temperatures of 72°F and 66°F degrees. Similarly, composite temperature and hourly profile of temperatures are used for the Summer and Winter peak models.

II. B. Comparison of FPL's Current and Previous Load Forecasts

FPL's current load forecast is significantly changed from the load forecast presented in its 2007 Site Plan. Two significant factors have been the primary factors in this change in the current load forecast compared to the load forecast presented in the 2007 Ten Year Site Plan. First, FPL has utilized the November 2007 population projections issued by BEBR, which are lower than the projections utilized in the load forecasts presented in the 2007 Site Plan. Second, Lee County Electric Co-Operative (Lee County) has contracted with FPL to serve a portion of its load starting in 2010 and to serve its full load beginning in 2014.

The net effects of these two factors is that FPL's load, compared to the load forecast presented in the 2007 Site Plan, is projected to grow at a somewhat slower rate for 2008 through 2013. Then, due in large part to the fact that FPL will begin serving Lee County's full load in 2014, the load is projected to be higher in 2014 through 2017.

Although the projected growth pattern of FPL's load has changed; somewhat less growth in 2008 through 2013, followed by higher growth in 2014 through 2017, the total growth projected by FPL for the ten-year reporting period of this document is still significant.

II.C. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class for the forecasting period of 2008-2026 and are adjusted to match the Net Energy for Load (NEL) forecast. The results of these sales forecasts for the years 2008-2017 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and NEL forecast are outlined below.

1. <u>Residential Sales</u>

Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, Florida Real Personal Income, Cooling and Heating Degree-Hours as explanatory variables, as well as a dummy variable for hurricanes and other outliers. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. To capture economic conditions, the model includes Florida's Real Personal Income. The degree of economic prosperity can, and does, affect residential electricity sales. The impact of weather is captured by the Heating Degree-Hours and Cooling Degree-Hours. Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted.

2. Commercial Sales

The commercial sales forecast is also developed using a regression model. Commercial sales are a function of the following variables: Florida Non-Agricultural Employment, commercial real price of electricity, Cooling Degree-Hours, as well as dummy variable for hurricanes. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree-Hours are used to capture weather-sensitive load in the commercial sector.

3. Industrial Sales

Industrial sales were forecasted using a linear multiple regression model. The linear multiple regression model utilizes the following variables: Florida Housing Starts, Cooling Degree-Hours, and several dummy variables for outliers, hurricanes, and months. The Cooling Degree-Hour term is used to capture the weather-sensitive load in the industrial class.

4. Railroad & Railways Sales and Street and Highway Sales

The forecast for street and highway sales is developed using historical usage patterns and multiplying these usage levels by the number of forecasted customers. The forecast of sales to railroad & railways is developed using an econometric model with the Florida population as the primary driver and several monthly dummy variables to capture seasonality. This class consists solely of the Miami-Dade County's Metrorail system.

5. Other Public Authority Sales

The sales for other public authority sales are developed using historical usage patterns.

6. **Total Sales to Ultimate Customer**

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual NEL.

7. **Sales for Resale**

Sales for resale (wholesale) customers are composed of municipalities and/or electric co-operatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Currently, there are three customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of Key West, Florida (City of Key West), and Miami-Dade County. However, starting in January 2010, Lee County will also be a customer in this class.

Sales to the City of Key West are forecasted using a regression model. Forecasted sales to the Florida Keys are based on assumptions regarding their contract demand and expected load factor. Miami-Dade County sells 60 MW to Progress Energy. Line losses associated with this sale are billed to Miami-Dade under a wholesale contract. Lee County has contracted for FPL to supply a portion of their load beginning in January 2010 and for FPL to supply their total load beginning in January 2014 through December 2033. Forecasted sales to Lee County are based on assumptions regarding their contract demand and expected load factor.

II.D. Net Energy for Load (NEL)

An econometric model is developed to produce an NEL forecast. The key inputs to the model are: the real price of electricity, Heating and Cooling Degree-Hours, and Florida Real Personal Income.

Once the NEL forecast is obtained using the above-mentioned methodology, the results are then compared for reasonableness to the NEL forecast generated using the total sales forecast. The sales by class forecasts previously discussed are then adjusted to match the NEL from the annual NEL model.

The forecasted NEL values for 2008 – 2017 are presented in Schedule 3.3 that appears at the end of this chapter.

II.E. System Peak Forecasts

The rate of absolute growth in FPL system peak load has been a function of a growing customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the peak forecast models to capture these behavioral relationships. In addition, as previously discussed, the introduction of the Lee County load beginning in January 2010 is a new factor in FPL's 2008 load forecast that is addressed in the forecast models.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2008–2017 are presented in Schedules 3.1 and 3.2 as well as in Schedules 7.1 and 7.2.

1. System Summer Peak

The Summer peak forecast is developed using an econometric regression model. This econometric model utilizes the following explanatory variables: total average customers, the real price of electricity, Florida Real Personal Income, average temperature on peak day, and a heat buildup weather factor consisting of the sum of the Cooling Degree -Hours during the peak day and three prior days.

2. System Winter Peak

The Winter peak forecast is developed using the same econometric regression methodology as is used for Summer peak forecasts. The Winter peak model is a per customer model which contains the following explanatory variables: the square of the minimum temperature on the peak day and Heating Degree-Hours for the prior day as well as for the morning of the Winter peak day. The model also includes an economic variable: Florida Real Personal Income.

3. Monthly Peak Forecasts

Monthly peaks are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peaks (Summer = April-October, Winter = November-March.)

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.F. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2008-2026 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

Schedule 2.1
History and Forecast of Energy Consumption
And Number of Customers by Customer Class

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)

2013	25,414	380	25,034	0	1,083	375	822	236	22,898
2014	26,576	1,076	25,500	0	1,110	430	837	274	23,925
2015	27,241	1,106	26,136	0	1,139	486	852	312	24,452
2016	27,932	1,135	26,797	0	1,164	535	867	345	25,021
2017	28,621	1,165	27,456	0	1,189	583	880	378	25,591

Historical Values (1998 - 2007):

Col. (2) - Col. (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 1997 through 2006 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial /Industrial Demand Reduction (CDR). Col.(5) - Col.(9) for year 2004 are "estimated actuals" and are August values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8).

Projected Values (2008 - 2017):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col. (9) represent all incremental conservation and cumulative load control. These values are projected August values and the conservation values are based on projections with a 1/2006 starting point for use with the 2006 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Historical Values (1998 - 2007):

Col. (2) - Col. (4) are actual values for historical winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col.(9) for 1996/97 through 2005/06 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial/Industrial Demand Reduction (CDR).Col.(5) - Col.(9) for year 2004/05 are "estimated actuals" and are January values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col. (2) - Col. (6) - Col. (8).

Projected Values (2008 - 2017):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col.(9) represent all incremental conservation and cumulative load control. These values are projected January values and the conservation values are based on projections with a 1/2004 starting point for use with the 2004 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990s and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of potential new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2007 and early 2008 resource planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Evaluate the competing options and resource plans in regard to system economics and non-economic factors; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

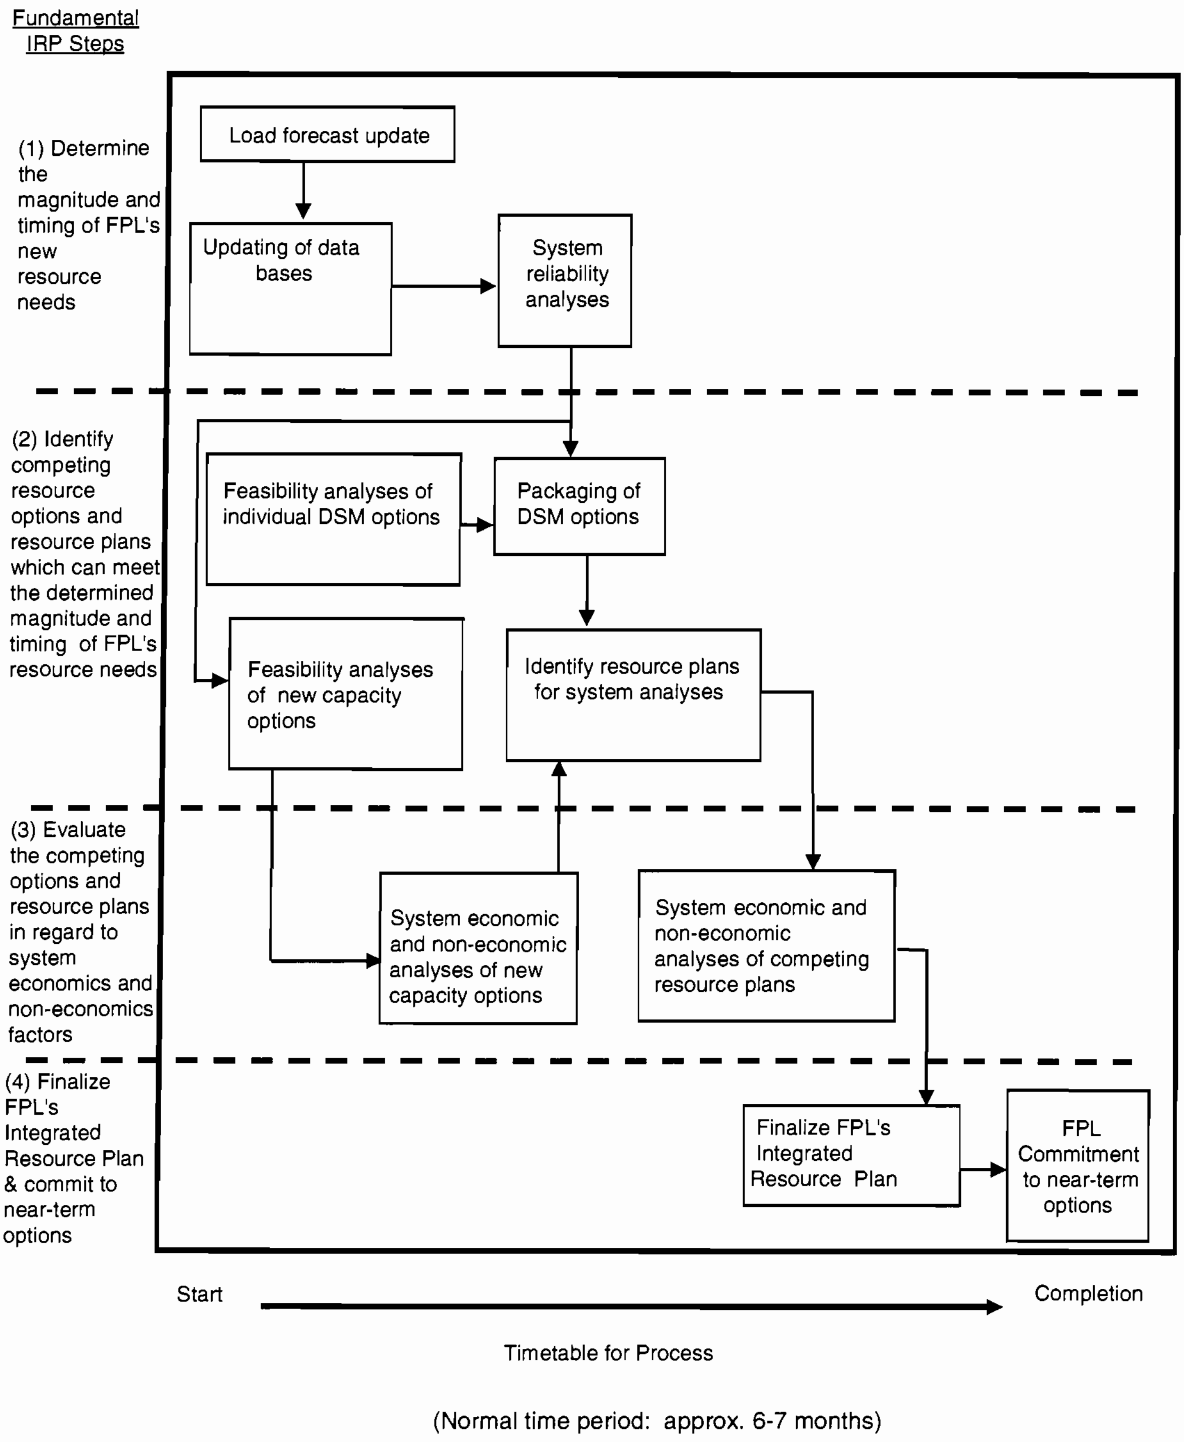

Figure III.A.1: Overview of FPL's IRP Process

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps, determining the magnitude and timing of FPL's resource needs, is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a reliability, or resource adequacy, assessment for the utility system.

Step 1 typically starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information that is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) firm capacity power purchases, and (3) DSM implementation.

The first of these assumptions is based on FPL's ongoing engineering and construction activities to add near-term capacity. These construction activities include two new combined cycle (CC) units at FPL's West County Energy Center (WCEC) site scheduled to come in-service by mid-2009 and mid-2010 respectively. FPL selected these CC units, designated as WCEC 1 & 2, after conducting a Request for Proposals (RFP) solicitations and evaluating the options received in response to the RFP. The need for these additions was approved by the FPSC, and the Governor and Cabinet, acting as the Siting Board, approved FPL's Site Certification Application for the units.

The second of these assumptions involves firm capacity power purchases. These firm capacity purchases are from a combination of utility and independent power producers. Details, including the annual total capacity values for these purchases are presented in Tables I.B.1 and I.B.2. These purchased capacity amounts were incorporated in FPL's recent resource planning work.

The third of these assumptions involves DSM. Since 1994, FPL's resource planning work has assumed that the DSM MW called for in FPL's approved DSM Goals will be achieved per plan as has historically been the case. This was again the case in FPL's most recent planning work as its new DSM Goals that address the years 2005 through 2014, and that were approved by the FPSC in August 2004, are assumed to be achieved per plan. In addition, FPL's resource planning also incorporated a significant amount of additional cost-effective DSM through 2014 that FPL identified after FPL's DSM Goals had been set. In addition, FPL is also assuming continued DSM implementation in 2015 - 2017 at annual implementation rates commensurate with DSM implementation rates projected for the years immediately preceding 2014. In total, these projected DSM efforts will result in FPL implementing approximately 1,539 MW of cost-effective DSM from August 2006 through August 2017 beyond the significant amount of DSM previously achieved by FPL. These additional MWs of DSM were also accounted for prior to making projections of new resource needs.

These key assumptions, plus the other updated information, are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the generation resource adequacy of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss–of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program used by FPL.

The result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. Information regarding the timing and magnitude of these resource needs is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analyses of new capacity options are conducted to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs. In similar analyses, feasibility analyses of new DSM options and/or continued growth in existing DSM options are conducted.

The individual new resource options emerging from these feasibility options are then typically "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using spreadsheet and/or dynamic programming techniques.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs are identified.

Step 3: Evaluate the Competing Options and Resource Plans in Regard to System Economics and Non-Economic Factors:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for evaluating these resource options and resource plans. In 2007, once the resource plans were developed, FPL utilized the P-MArea production cost model and a Fixed Cost Spreadsheet to perform the economic analyses. The P-MArea model is the model used by FPL to develop the Fuel Cost Budget and to conduct other production cost-related analyses.

FPL also utilized several other models in the economic evaluation portion of its resource planning work. For DSM analyses, FPL used its DSM cost-effectiveness model; an FPL spreadsheet model utilizing the FPSC's approved methodology for analyzing the cost-effectiveness of individual DSM measures/programs, and its non-linear programming model for analyzing the potential for lowering system peak loads through additional load management capacity.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases in which the DSM contribution was assumed as a given and the only competing options were new generating units and/or purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans were evaluated on a cumulative present value revenue requirement (CPVRR) basis.

Other factors are also included in FPL's evaluation of resource options and resource plans. While these factors may have an economic component or impact, they are often discussed in quantitative, but non-economic terms, such as percentages, etc. rather than in terms of dollars. These factors are often referred to by FPL as "system concerns" that include maintaining/enhancing fuel diversity in the FPL system, maintaining a regional imbalance between load and generating capacity, particularly in Southeastern Florida, and moving in the direction of lowering system carbon dioxide (CO_2) emissions. In conducting the evaluations needed to determine which resource options and resource plans are best for FPL's system, both the economic and non-economic evaluations are conducted with an eye to whether the system concern is positively or negatively impacted by a given resource option or resource plan.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps were used to develop the future generation plan. This plan is presented in the following section.

III.B Incremental Resource Additions

FPL's projected incremental generation capacity additions/changes for 2008 through 2017 are depicted in Table III.B.1 (the planned DSM additions through 2017 were shown previously in Table I.D.1). These capacity additions/changes result from a variety of actions including: changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, increases in generating capacity at FPL's four existing nuclear units, and by construction of both committed and proposed new generating units.

As shown in Table III.B.1, the capacity additions are largely made up of committed new construction, new purchases, and proposed self-build alternatives. (The additional DSM MW are not presented in this table but have been accounted for prior to making these new capacity option projections.) In 2009, the table shows previously committed generation additions: the new 1,219 MW CC unit at the West County Energy Center (WCEC) that is scheduled to be placed into service in June 2009 (WCEC Unit 1), and a second 1,219 MW CC unit at WCEC (WCEC Unit 2) that is scheduled to be placed into service in June 2010.

FPL is also currently assuming, for planning purposes, that contract extensions and/or new contracts will be reached with several existing renewable energy suppliers whose contracts with FPL are set to expire within this ten-year period. In addition, FPL's resource plan reflects its intent to obtain additional capacity and/or energy from the Renewable RFP solicitations or its own renewable energy development efforts.

For purposes of this planning document, FPL is assuming that 269 MW of firm capacity from renewable facilities will be added to FPL's system in the ten-year reporting period. This is discussed further in Section III.F.

In addition, FPL will be adding approximately 414 MW of proposed capacity uprates to FPL's four existing nuclear units in the 2011 and 2012 time period. Three uprates are projected to come in-service in December 2011, May 2012, and June 2012, respectively. Therefore, the 310 MW of capacity from these three units is accounted for in Summer reserve margin calculations beginning with the Summer of 2012. The fourth uprate is projected to come in-service in December 2012. Therefore, its 104 MW of capacity is accounted for in Summer reserve margin calculations beginning with the Summer of 2013.

Also projected is the proposed addition of a third new 1,219 MW unsited CC unit at the West County Energy Center site (WCEC 3) similar to the WCEC 1 & 2 units. This proposed new unit would have a June 2011 in-service date.

For purposes of this planning document, FPL also projects the construction of one unsited CC in 2014, and two unsited CC in 2016 to meet its remaining capacity needs through 2017. As an alternative to the 2014 unsited CC unit, FPL is currently evaluating the repowering of existing plants that would be completed in 2013 and 2014. The potential repowering projects are not shown in the table because FPL is currently analyzing these potential additions at the time the 2008 Site Plan is being prepared.

Table III.B.1: Projected Capacity Changes for FPL [1]

Projected Capacity Changes and Reserve Margins for FPL [1]			
		Net Capacity Changes (MW)	
		Winter [2]	Summer [3]
2008	Changes to Existing Units	41	14
	Changes to Existing Purchases [4]	(836)	---
2009	West County Unit #1 [5]	---	1,219
	Changes to Existing Units	28	1
	Changes to Existing Purchases [4]	(326)	(431)
2010	West County Unit #1 [5]	1,335	---
	West County Unit #2 [5]	---	1,219
	Extension Renewable Capacity Purchases	98	98
	Changes to Existing Purchases [4]	(559)	(455)
2011	West County Unit #2 [5]	1,335	---
	West County Unit # 3 [5]	---	1,219
	New Renewable Capacity Purchases	---	32
	Extension Renewable Capacity Purchases	45	45
	Changes to Existing Purchases [4]	(46)	(45)
2012	Changes to Existing Purchases [4]	---	(156)
	West County Unit # 3 [5]	1,335	---
	New Renewable Capacity Purchases	126	94
	Changes to Existing Nuclear Units	103	310
2013	Changes to Existing Nuclear Units	311	104
	Changes to Existing Purchases [4]	(180)	---
2014	Unsited 3 x 1 CC #1 [5]	---	1,219
2015	Unsited 3 x 1 CC #1 [5]	1,335	---
2016	Unsited 3x1 CC # 2 [5]	---	1,219
	Unsited 3x1 CC # 3 [5]	---	1,219
	Changes to Existing Purchases [4]	(930)	(1,311)
2017	Unsited 3x1 CC # 2 [5]	1,335	---
	Unsited 3x1 CC # 3 [5]	1,335	---
	Changes to Existing Purchases [4]	(390)	---
	TOTALS =	**5,495**	**5,614**

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of year shown.
(3) Summer values are values for August of year shown.
(4) These are firm capacity and energy contracts with QF, Utilities and other purchases. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

III.C Issues Impacting FPL's Resource Planning Work

FPL's 2007 and early 2008 planning efforts have continued to address two issues, or system concerns, that were identified in previous Site Plans as being items of on-going importance. Those two system concerns are: (1) the need to maintain fuel diversity in the FPL system and (2) the need to address the imbalance between regional load and generating capacity located in Southeastern Florida.

In addition, a third factor affecting resource planning was introduced in 2007: Florida Governor Crist's Executive Orders. These Orders addressed a number of issues including two of particular interest to electric utilities. The first of these was a goal to provide 20% of the energy produced by electric utilities from renewable, non-emitting sources. The second was to move in the direction of significantly reducing greenhouse gas emissions by 2017 and in later years.

1. **System Fuel Diversity**

FPL is working to increase system fuel diversity in variety of ways. In 2007, FPL sought approval from the FPSC to add two new advanced technology coal units to its system. These two new units would have been placed in-service in 2013 and 2014. However, due to concerns over greenhouse gas emissions, FPL was unable to obtain approval for these units. Consequently, FPL does not believe that new advanced technology coal units are viable generation options for the ten-year reporting period of this Site Plan.

FPL also sought approval for increased nuclear generation capacity in 2007 in two filings with the FPSC. The first filing was to increase capacity at each of FPL's four existing nuclear units by 103 or 104 MW. These capacity "uprates", that in total will add 414 MW to the FPL system in the 2011/2012 time period, were approved by the FPSC in January 2008. The second filing was for approval for FPL to proceed with plans and expenditures for two new nuclear units at FPL's existing Turkey Point site. These two new nuclear units are projected to add 2,200 to 3,040 MW to FPL's system, with the MW value dependent upon the technology eventually selected by FPL. The first of these units is projected to come in-service in 2018 (i.e., outside of the ten-year reporting period of this document) and the second unit to come in-service in 2020. The FPSC voted to approve the need for these two new nuclear units on March 18, 2008 and the FPSC is expected to issue the final order approving the units by mid-April 2008.

FPL also has been involved in activities to investigate adding or maintaining renewable resources as a part of its generation supply. One of these activities is a variety of discussions with existing facilities aimed at maintaining or extending current agreements that are scheduled to end during the ten-year reporting period of this document. Another activity is to attempt to solicit cost-effective new renewable projects. FPL issued a Request for Proposals (RFP) for new renewable energy capacity and energy in 2007 and plans to issue another one in April 2008, Other efforts to utilize renewable energy are discussed in Section III.F.

In the future, FPL will continue to identify and evaluate alternatives that may maintain or enhance fuel diversity in its capacity resource mix. FPL also plans to maintain the ability to utilize fuel oil at those existing units that have that capability, although cost factors currently limit the expected use of these facilities.

2. **Southeastern Florida Imbalance**

In recent years an imbalance had developed between regionally installed generation and peak load in Southeastern Florida. A significant amount of energy required in the Southeastern Florida region during peak periods was being provided through the transmission system from plants located outside the region. FPL's prior planning work concluded that either additional installed capacity in this region, or transmission capacity capable of delivering additional electricity from outside the region, would be required to address this imbalance.

Partly because of the lower transmission-related costs resulting from their location, three recent capacity additions: Turkey Point 5, WCEC Units 1 & 2, were evaluated as the most cost-effective options to meet FPL's 2007, 2009, and 2010 capacity needs, respectively. Adding these units will significantly reduce the imbalance between generation and load in Southeastern Florida.

In addition, FPL is proposing to add the WCEC 3 unit in 2011, and will be adding the already approved plans to increase capacity at FPL's existing two nuclear units at Turkey Point in 2011/2012. The result of these committed and proposed generating unit additions in Southeastern Florida are expected to address the imbalance for most, if not all, of the 2008-2017 reporting period addressed in this document. However, the Southeastern Florida imbalance will remain a consideration in FPL's on-going resource planning work.

3. **Governor Crist's Executive Orders**

The Executive Orders, particularly the portions directing significant increases in renewable, non-emitting energy and decreases in greenhouse gas emissions, are being addressed by FPL in a variety of ways. In regard to renewable energy, FPL's efforts to procure capacity from renewable energy sources, and to build its own renewable energy facilities, is discussed in detail in Section III.F.

These renewable energy efforts have the potential to help lower greenhouse gas emissions. In addition, significant reductions (particularly of carbon dioxide, CO_2) will be accomplished by the approved capacity uprates at FPL's existing nuclear units and the proposed two nuclear units at FPL's existing Turkey Point site. Further reductions in greenhouse gas emissions are also expected from increasing the overall fuel efficiency of FPL's system through the addition of the approved new generating units WCEC 1 & 2, and proposed new WCEC 3 unit. FPL will also continue to look for cost-effective ways to further improve the efficiency of its system that will lead to even more greenhouse gas emission reductions.

Another important potential strategy that could help achieve these objectives is "repowering" one or more of FPL's existing generating plants. The repowering plan consists, in part, of replacing an existing steam plant with a heat rate of about 10,000 Btu/kWh, with a new state-of-the-art advanced combined cycle unit that uses natural gas as the primary fuel, with a heat rate of less than 6,600 Btu/kWh. In addition, this new, highly efficient, repowered unit would result in a net increase in generating capacity.

The principal advantage of repowering is that, in addition to providing a net increase in generating capacity to meet growing demand, in a manner that is cost-competitive with adding a new generating unit, the repowering also converts a significant amount of existing, low efficiency, steam generation that utilizes fuel oil as much as, if not more than, natural gas, into an equivalent amount of highly efficient, low emission, gas-fueled, advanced combined cycle generation and thereby reduces fuel use and air emissions, including CO_2 emissions. As a result, such a repowering strategy could enable FPL to economically reduce, by 2017, CO_2 emissions to the level of CO_2 emissions in 2000, consistent with the 2017 CO_2 emissions target proposed in 2007 by Governor Crist, while still meeting FPL customers' electricity needs.

Before FPL can take concrete steps aimed at implementing a repowering strategy, it must complete a detailed evaluation of all aspects of repowering in order to ensure that its implementation would be beneficial to FPL's customers.

FPL's system CO_2 emission rate (amount of CO_2 emitted per MWh of electricity generated) is already relatively low due in large part to the overall efficiency of FPL's system. The efforts described above have the potential not only to continue the trend of steadily lowering FPL's already low CO_2 emission rate, but also to begin to lower total system CO_2 emissions despite increasing population growth.

III.D Demand Side Management (DSM)

FPL offers a wide variety of cost-effective DSM programs and a DSM-based renewable energy option to its customers. In addition, FPL is actively engaged in DSM research and development. These DSM efforts are discussed in the remainder of this section.

RESIDENTIAL DSM PROGRAMS

1. **Residential Building Envelope:** Offers incentives to residential customers to install energy efficient roof and ceiling insulation measures. FPL offers a maximum incentive of $1,676 per summer kW for ceiling insulation, a maximum incentive of $706 per summer kW for reflective roofs, and $1,518 per summer kW for other roofing technologies.

2. **Duct System Testing and Repair:** Provides reduced cost duct system testing to identify leaks in air conditioning duct systems, and encourages the repair of those leaks by qualified contractors. Incentives are offered for duct system repair. The maximum incentive is $466 per summer kW reduction.

3. **Residential Air Conditioning:** Offers incentives to customers to purchase higher efficiency heating, ventilating, and air conditioning equipment with incentive levels at a maximum of $1,429 and $1,643 per summer kW reduction for straight cooling and heat pumps, respectively. The program includes additional incentives for: 1) plenum repair measure, with a maximum incentive level of $412 per summer kW reduction; 2) air handler units with electronically commutated motors with a maximum incentive of $208 per summer kW; and, 3) units properly sized using FPL approved sizing software with a maximum incentive of $272 per summer kW.

4. **Residential Load Management (On Call Program):** Offers load control of major appliances/household equipment to residential customers in exchange for monthly electric bill credits. Direct load control equipment is installed on selected customer end-use equipment, allowing FPL to control these customer loads as needed. Qualifying equipment (and applicable monthly credits) includes central electric air conditioners ($3.00 for cycle units, and $9.00 for shed units), central electric heaters ($2.00 for cycle, and $4.00 for shed), conventional electric water heaters ($1.50), and swimming pool pumps ($3.00).

5. **Residential New Construction (BuildSmart):** Encourages the design and construction of energy efficient homes by offering education to contractors on energy efficiency measures, and providing construction design reviews and home inspections.

6. **Residential Low Income Weatherization:** Combines energy audits and incentives to encourage low income housing administrators to retrofit homes with energy efficiency measures. The housing authorities include: weatherization agency providers (WAPS), non-weatherization agency providers (non-WAPS), and other providers approved by FPL. The incentives are used by these providers to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting. FPL offers incentives for HVAC maintenance ($45), reduced air infiltration measures ($60), and room air conditioning replacement ($25).

7. **Residential Conservation Service:** Offers a walk-through energy audit, a computer generated Class A audit, and a customer-assisted energy audit. For customer-assisted energy audits, a mail-in, phone, and Internet audit option may be offered. FPL does not apply demand and energy savings from this program towards its DSM Goals.

BUSINESS DSM PROGRAMS

1. **Business Heating, Ventilating, and Air Conditioning (HVAC):** Offers business customers financial incentives to upgrade to higher efficiency HVAC equipment that exceed the minimum efficiencies mandated by the U.S. Department of Energy. The current FPL program includes: 1) a maximum thermal storage incentive up to $898 per summer kW reduction; 2) a maximum incentive for chillers up to $99 per summer kW; 3) incentives for energy recovery ventilator units with a maximum incentive up to $417 per summer kW reduction; 4) incentives for direct expansion (DX) units up to $168 per summer kW reduction and up to $498 per summer kW for efficient air conditioning room units; 5) a maximum incentive of $627 per summer kW for demand control ventilation systems including kitchen hood control; and 6) a maximum incentive of $102 per summer kW for electrically commutated motors for air conditioning systems.

2. **Business Efficient Lighting:** Offers business customers financial incentives to install high efficiency lighting measures at the time of replacement. The FPL current program offers an incentive of $0.65 to $2 per lamp on linear fluorescent plus a schedule of incentives for other efficient lighting technologies.

3. **Business Building Envelope:** Offers financial incentives to business customers to install high efficiency building envelope measures such as roof/ceiling insulation and reflective roof coatings. The current incentive structure offers incentives for summer kW reductions with a maximum incentive of $185 for ceiling insulation, $219 for roof insulation, $579 for reflective roofs, and $429 for window treatments.

4. **Business Custom Incentive:** Serves as a "catch-all" program for cost-effective business efficiency measures which are not included in other FPL programs. DSM measures must reduce or shift at least 25 kW during peak hours, have verifiable demand and energy savings, and pass FPL's cost-effectiveness testing.

5. **Business On Call:** Offers load control of central air conditioning units to both small non–demand-billed, and medium demand-billed, business customers in exchange for monthly electric bill credits. FPL offers incentive payments of $2.00 per ton.

6. **Commercial Industrial Demand Reduction (CDR):** Reduces peak demand by allowing the direct control of customer loads of 200 kW or greater during periods of extreme demand or capacity shortages. Participants contract for a firm demand level which may not be exceeded during load control periods. In return, participants receive a monthly credit of $4.68 per kW used during a specified controllable rating period, less their contracted firm demand. Any kW used in excess of the contracted firm demand level is re-billed at $4.68 per kW, plus a $0.99 penalty charge per kW of excess kW for each month of rebilling. Participants must provide a 5-year termination notice to discontinue service under this rider.

7. **Business Energy Evaluation:** Offers free standard level energy evaluations on-site and on-line. More detailed evaluations are available through this audit program with costs shared between FPL and the participating customer. Participation in FPL's other business DSM programs is promoted through this program.

8. **Commercial/Industrial Load Control:** Reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

9. **Business Water Heating:** Encourages the installation of energy-efficient heat recovery units or heat pump water heaters. A maximum incentive of $881 per summer kW reduction is available.

10. **Business Refrigeration:** Encourages the installation of controls and equipment to reduce the usage of electric strip heat for defrosting purposes. FPL offers a maximum incentive of $80 per summer kW reduction.

11. **Cogeneration and Small Power Production:** Facilitates FPL compliance with all regulatory requirements concerning qualifying facilities and small power producers. One role of the program is to assist customers in the evaluation of potential cogeneration

projects, including self-generation. FPL does not project demand and energy savings from this program towards its DSM Goals.

RENEWABLE ENERGY PROGRAM

Green Power Program (marketed as the *Sunshine Energy* ® program): A voluntary program providing interested residential and business customers with the opportunity to support renewable energy development. The program includes a special tariff, under which participating customers voluntarily pay a $9.75 monthly premium. In exchange, FPL purchases a 1,000 kWh block of tradable renewable energy credits. For every 10,000 residential customers participating in the program, FPL will cause to be developed 150 kW of solar capacity in Florida.

RESEARCH AND DEVELOPMENT PROGRAMS

Conservation Research and Development Program (CRD): An umbrella research project under which new DSM technologies are analyzed. Several FPL DSM programs have emerged from the CRD program, including the business Building Envelope, Business On Call, and Residential New Construction programs. The program has also resulted in the addition of cost-effective measures to existing programs, such as the proposed inclusion of Energy Recovery Ventilators to the Business HVAC Program. FPL operates the CRD program based on DSM Plan approval, or for 6 years, whichever occurs first, with a spending cap of $2,500,000 for the period.

Residential Thermostat Load Control Pilot Project: On June 15, 2007 FPL filed a petition with the Commission for the Residential Thermostat Load Control Pilot Project. A typical barrier to customer acceptance of utility load control programs is reluctance to surrender control of heating and air conditioning appliances. Consequently, for an initial 24-month period, FPL is proposing to evaluate whether the benefits of the existing On-Call Program can be expanded through use of a new generation of communication and control technologies that put residential customers in charge of decisions that could lower energy costs, while allowing customers to override FPL control of their heating and air conditioning appliances. The Commission approved FPL's request on August 14, 2007, and issued Consummating Order 07-0719 TRF-EG on September 28, 2007.

DSM SUMMARY:

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include both conservation initiatives and load management. FPL's DSM efforts through 2007 have resulted in a cumulative Summer peak reduction of approximately 3,958 MW at the generator and an estimated cumulative energy saving of approximately 42,301 Gigawatt Hour (GWh) at the generator. Accounting for reserve margin requirements, FPL's DSM efforts through 2007 have eliminated the need to construct the equivalent approximately 12 new 400 MW generating units.

III.E Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV bulk transmission lines that must be certified under the Transmission Line Siting Act.

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (KV)	(7) Capacity (MVA)
FPL	St. Johns [1/]	Pringle	25	Dec-08	230	759
FPL	Manatee	BobWhite	30	Dec-11	230	1190

1/ Final order certifying the corridor was issued on April 21, 2006. This project will be completed in two phases. Phase I consists of 4 miles of new 230kV line (Pringle to Pellicer) and is scheduled to be completed by Dec-2008. Phase II consists of 21 miles of new 230kV line (St. Johns to Pellicer) and is scheduled to be completed by Jun-2011.

Table III.E.1: List of Proposed Power Lines

In addition, there will be transmission facilities needed to connect several of FPL's committed and proposed capacity additions to the system transmission grid. These transmission facilities for the committed capacity additions at the WCEC site; WCEC 1 & 2, and the proposed capacity addition at the WCEC site, WCEC 3, are described on the following pages.

III.E.1 Transmission Facilities for West County Energy Center (WCEC) Unit 1

The work required to connect West County Energy Center (WCEC) Unit 1 in 2009 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 4 breakers to connect the three combustion turbines (CT) and one steam turbine (ST).
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 230 kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1-580 MVA), one for each CT, and one for the ST.
4. Add a new Bay #4 with 3 breakers at the Corbett 230 kV main switchyard. Connect one string buss from the collector yard and relocate the Alva 230 kV terminal from Bay #3 to new Bay #4.
5. Connect second collector string buss to Bay #3.
6. Add relays and other protective equipment.
7. Breaker replacements:
   Corbett Sub – Replace eight (8) 230 kV breakers
   Ranch Sub – Replace five (5) 138 kV breakers
   Midway Sub – Replace one (1) 230 kV breaker
   Levee Sub – Replace one (1) 230 kV breaker
   Dade Sub – Replace two (2) 138 kV breakers

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.E.2 Transmission Facilities for West County Energy Center (WCEC) Unit 2

The work required to connect West County Energy Center (WCEC) Unit 2 in 2010 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 4 breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 500kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. At Corbett Sub, install one breaker and relocate Martin #2 500 kV line from Bay 2S to Bay 2N. Install one West County 500 kv string bus into Bay 2S.
5. At Corbett Sub, install one breaker and second West County 500 kV string bus into Bay 1S.
6. Add relays and other protective equipment.
7. Breaker replacements:
   Dade Sub – Replace one (1) 138 kV breaker
   Levee Sub – Replace four (4) 230 kV breakers
   Midway Sub – Replace three (3) 230 kV breakers
   Ranch Sub – Replace one (1) 230 kV breaker

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.E.3 Transmission Facilities for West County Energy Center (WCEC) Unit 3

The work required to connect the proposed West County Energy Center (WCEC) Unit 3 in 2011 with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 4 breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Build new Sugar 230 kV substation on WCEC site.
3. Construct two string busses to connect the collector busses and main switchyard to Sugar 230kV Substation.
4. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
5. At Corbett Sub relocate Germantown 230 kV line terminal from Corbett to Sugar Sub.
6. At Corbett Sub relocate Broward/Yamato 230 kV line terminal from Corbett to Sugar Sub.
7. At Corbett Sub install new Sugar 230 kV line terminal in Bay 2W
8. At Corbett Sub, install one 5-ohm reactor on the 230 kV side of the 500/230 kV autotransformer.
9. Add relays and other protective equipment Corbett, Sugar, Rainberry, Broward, Yamato, and Marlin Subs

II. Transmission:

1. Relocate Germantown 230 kV line from Corbett to Sugar.
2. Relocate Broward/Yamato 230 kV line from Corbett to Sugar.
3. Construct one (1) mile 230 kV 1190 MVA line from Sugar to Corbett

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various renewable energy technologies. For purposes of discussing FPL's renewable energy efforts in this document, those efforts will be placed into five categories.

1) **Early Research & Development Efforts:**

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970s in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities in Florida on both a daily and annual basis. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-kilowatt (kW) system was placed into operation in 1984. (The system was removed in 1990 to make room for substation expansion after the testing of this PV installation was completed.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed below).

2) **Demand Side & Customer Efforts:**

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was no longer cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980s, FPL introduced another renewable energy program, FPL's Passive Home Program. This program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for 6 passive homes with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test were deemed to be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

FPL then analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach did not require all of its customers to bear PV's high cost, but facilitated the use of renewable energy by customers who were interested. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund that FPL used to make PV purchases in bulk quantities. PV modules were then installed and deliver PV-generated electricity directly into the FPL grid, thus displacing an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach for this program, which has been termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL began the effort in 1998 and received approximately $89,000 in contributions (that significantly exceeded the goal of $70,000). FPL purchased the PV modules and installed them at FPL's Martin Plant site.

FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was FPL's Photovoltaic Research, Development, and Education Project. This demonstration project's objectives were to: increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks (as well as the total annual energy capabilities of roof tile PV systems), and assess the homeowner's financial benefits and costs of PV roof tile systems. This project was completed in 2003.

The second effort initiated in 2000 was the Green Energy Project. The objectives of this Project were to: determine customer interest in an on–going renewable energy program, determine their price responsiveness and views on the different renewable technologies, and identify potential renewable energy supply sources that would meet the forecasted customer demand for this type of product. This Project formed the basis for FPL's Green Power Pricing Research Project, and then led to FPL's Business Green Energy Research Project.

Both the Green Power Pricing Research Project and the Business Green Energy Research Project examined the feasibility of purchasing tradable renewable energy credits generated from renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable sources. Customers who participate are charged a premium for purchasing the tradable renewable energy credits associated with electric energy generated by these sources.

Development of the Green Pricing Research Project was completed and filed with the FPSC in August 2003. As part of this process, a supply contract was put into place that allows FPL to match supply with demand for green energy. Tradable renewable energy credits are used to supply the renewable benefits required of this project. The FPSC approved the program on December 2, 2003 with program implementation during the first quarter of 2004. The project was offered to customers as FPL's Sunshine Energy® program. As part of the project, FPL made a commitment that 150 kW of solar capacity would be put in place for every 10,000 program participants. The Business Green Energy Research Project focused on determining the interest and needs for business customers in this area. In 2006 FPL petitioned the FPSC for approval to make the Green Pricing Research Project a permanent program and expand eligibility to business customers. This approval was granted in the fourth quarter of 2006.

As of the end of 2007, FPL had 36,918 participants in the program. The Rothenbach Park solar array in Sarasota was commissioned as the first large scale PV facility as a direct result of FPL's Sunshine Energy® renewable program. The 250 kilowatt solar array at Rothenbach Park is the largest solar facility in the state of Florida and one of the largest in the Southeastern United States. Construction on the new solar facility was completed in October 2007.

Several additional solar initiatives have also been developed through the Sunshine Energy program including support for schools. The Sunshine Energy program support of installing PV at schools is a continuation of previous FPL renewable activities involving schools. In 2003, as part of the State of Florida's PV for Schools program, FPL worked with three schools to install 4.8 kW PV systems.

FPL has also been investigating fuel cell technologies through monitoring of industry trends, discussions with manufacturers, and direct field trials. From 2002 through the end of 2005, FPL conducted field trials and demonstration projects of Proton Exchange Membrane (PEM) fuel cells with the objectives of serving customer end-uses while evaluating the technical performance, reliability, economics, and relative readiness of the PEM technology. The demonstration projects were conducted in partnership with customers and included 5 locations. The research projects were useful to FPL in identifying specific issues that can occur in field applications and the current commercial viability of this technology. FPL will continue to monitor the progress of these technologies and conduct additional field evaluations as significant developments in the fuel cell technologies occur.

In addition, FPL assists customers who are interested in installing PV equipment at their facilities. In support of Florida Administrative Code Rule 25-6.065, Interconnection of Small Photovoltaic Systems, FPL works with customers to interconnect these customer-owned PV systems. Through February 2008, approximately 110 customer systems (predominantly residential but with a few business systems) have been interconnected.

3) **Supply Side Efforts – Power Purchases:**

FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy and as-available energy have been purchased by FPL from these types of facilities. (Please refer to Tables I.B.1, I.B.2, and Table I.C.1).

FPL is seeking out cost-effective Power Purchase Agreements (PPAs) with any and all potential renewable energy providers. FPL issued a Renewable Request for Proposals (RFP) in 2007 that solicited proposals that offered capacity and/or energy from new renewable energy facilities. FPL plans to issue another Renewable Energy RFP in April 2008.

In regard to certain of the existing contracts that are currently scheduled to end in the near-term, and proposals resulting from the RFP process, FPL has assumed that some of this firm capacity will be available during the ten-year reporting period of this document through extended and/or new contracts. Firm renewable energy capacity from these sources, and from the FPL development activities discussed below, are assumed for planning purposes to provide 269 MW through this reporting period.

4) **Supply Side Efforts – FPL Facilities:**

FPL is in the process of developing a wind generation project on South Hutchinson Island, in St. Lucie County known as the "St. Lucie Wind project" which may consist of up to six (6) wind turbine generators (i.e., that do not use water or emit pollutants of any kind) capable of generating up to approximately 13.8 MW of wind generation. In addition, other wind development efforts are currently underway on Florida's coastline. FPL's goal is to start construction on the St. Lucie Wind project in 2008 with completion in 2009.

FPL is in the process of developing three large scale proposed solar thermal and/or photovoltaic generation facilities, with plans to install up to 350 MW of overall solar capacity by 2012. All of the solar generation facilities will be constructed within FPL's service territory. FPL is in the process of locating sites for these three solar projects. The first solar project is being designed to deliver up to 10 MW of solar generation to FPL's customers. One potential location for this project is at NASA's Kennedy Space Center in Brevard County Florida, where FPL and NASA are actively engaged in studies to determine if the Kennedy Space Center property may be feasible. The second solar project is being designed to deliver up to 20 MW. The third solar project is being designed for up to 50 MW of solar energy to FPL's customers and the existing Martin plant site is being considered as a potential location for the project. FPL is in the process of locating and/or finalizing sites for these three solar projects. FPL's goal is to start construction on all three solar projects mentioned in 2008 with completion in 2009/2010. FPL is also in the process of identifying the feasibility of technologies, locating sites and potential equipment suppliers for the remaining portion of the projected 350 MW of solar generation.

FPL is currently in the process of evaluation to determine each project's costs, impacts to the community and the environment as part of the overall development analysis. For those projects it determines to be both technically and economically viable, FPL plans to seek approval for the projects and recovery of the associated costs from the FPSC.

For planning purposes, FPL expects that the energy delivered from these proposed renewable facilities to be "as available", non-firm energy. This is due to the intermittent nature of these renewable resources. Once site-specific operating data has been gathered for an appropriate amount of time, FPL will then re-evaluate the actual output from each renewable facility to determine what portion, if any, of this output can be projected as firm capacity in its resource planning work.

5) **<u>Ongoing Research & Development Efforts:</u>**

FPL has developed alliances with several Florida Universities to promote development of emerging technologies. For example, an alliance as been established with the newly formed Center of Excellence in Ocean Energy Technology at Florida Atlantic University (FAU), which will focus on the commercialization of ocean current, ocean thermal (i.e., energy conversion as well as cold water air conditioning) and hydrogen technologies. FPL has been taking the lead in assisting FAU with the discussions being held with the U.S. Department of the Interior's Minerals Management Service Department (MMS). MMS is working to establish the permitting process for ocean energy development on the outer continental shelf.

FPL has also developed an alliance with the University of Florida to support their studies of biomass renewable potential and wind studies in the state. In addition, FPL has partnered with Florida Institute of Technology on fuel cell technology.

FPL has also been in discussion with several private companies on several emerging technology initiatives including ocean current, ocean thermal, hydrogen, fuel cell technology, biomass, biofuels and energy storage.

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980s, FPL relied primarily on a combination of fuel oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil–fired generation. In the early 1980s FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit 4 in 1989. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP.

The trend since the early 1990s has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective combined cycle generating units and the ready availability of natural gas. This planning document reflects an evolution in that trend in recognition that, although efficient gas-fired generation continues to provide significant benefits to FPL's customers, adding natural gas-fired additions exclusively would, in the long term, create an unbalanced generation portfolio. FPL has committed to add two new gas-fired CC units at the West County Energy Center (WCEC) site in 2009 and 2010, and is proposing to add a third CC unit at the WCEC site in 2011. These CC units will provide highly efficient generation that will benefit the entire FPL system by reducing transmission-related costs, mitigate the load-to-generation imbalance in Southeastern Florida, and dramatically improve the overall system generation efficiency.

FPL's future resource planning work will remain focused on identifying and evaluating alternatives that would maintain and/or enhance FPL's long-term fuel diversity. These fuel diverse alternatives may include: the purchase of power from renewable energy facilities, addition of FPL-owned renewable energy facilities, obtaining access to diversified sources of natural gas such as liquefied natural gas (LNG), preserving FPL's ability to utilize fuel oil at its existing units, and increased utilization of nuclear energy. (As previously discussed in the Executive Summary of this document, new advanced technology coal generating units are not considered as viable options in Florida in the ten-year reporting period of this document due to concerns over greenhouse gas emissions.) The evaluation of the feasibility and cost-effectiveness of these, and other possible alternatives, will be an ongoing part of future planning cycles.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2017 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

2. Fossil Fuel Price Forecasts

Fossil fuel price forecasts, and the resulting projected price differentials between fuels, are major drivers used in evaluating alternatives for meeting future generating capacity needs. FPL's forecasts are generally consistent with other published contemporary forecasts.

a) Fossil Fuel Price Forecast Methodology

Future oil and natural gas prices, and to a lesser extent, coal and petroleum coke prices, are inherently uncertain due to a significant number of unpredictable and uncontrollable drivers that influence the short- and long-term price of oil, natural gas, coal, and petroleum coke. These drivers include: (1) current and projected worldwide demand for crude oil and petroleum products; (2) current and projected worldwide refinery capacity/production; (3) expected worldwide economic growth, in particular in China and the other Pacific Rim countries; (4) Organization of Petroleum Exporting Countries (OPEC) production and the availability of spare OPEC production capacity and the assumed growth in spare OPEC production capacity; (5) non-OPEC production and expected growth in non-OPEC production; (6) the geopolitics of the Middle East, West Africa, the Former Soviet Union, Venezuela, etc., as well as, the uncertainty and impact upon worldwide energy consumption related to U. S. and worldwide environmental legislation, politics, etc.; (7) current and projected North American natural gas demand; (8) current and projected U.S., Canadian, and Mexican natural gas production; (9) the worldwide supply and demand for LNG; and (10) the growth in solid fuel generation on a U. S. and worldwide basis.

The inherent uncertainty and unpredictability in these factors today and tomorrow clearly underscores the need to develop a set of plausible oil, natural gas, and solid fuel (coal and petroleum coke) price scenarios that will bound a reasonable set of long-term price outcomes. In this light, FPL developed and utilized Low, Medium, and High price forecasts for oil, natural gas, and solid fuel in much of its 2007 and early 2008 resource planning work.

FPL's Medium price forecast methodology is consistent for oil and natural gas. For oil and natural gas commodity prices, FPL's Medium price forecast applies the following methodology: (1) for 2007 through 2009, the methodology used the July 31,2007 forward curve for New York Harbor 1% sulfur heavy oil, U. S. Gulf Coast 1% sulfur heavy oil, and Henry Hub natural gas commodity prices; (2) for the next two years (2010 and 2011), FPL used a 50/50 blend of the July 31, 2007 forward curve and projections from The PIRA Energy Group; (3) for the 2012 through 2020 period, FPL used the annual projections from The PIRA Energy Group, and (4) for the period beyond 2020, FPL used the real rate of escalation provided in the Energy Information Administration (EIA) *Annual Energy Outlook 2007* publication. FPL assumed a 2.5% annual rate of escalation to convert real prices to nominal prices. In addition to the development of oil and natural gas commodity prices, nominal price forecasts also were prepared for oil and natural gas transportation costs. The addition of commodity and transportation forecasts resulted in delivered price forecasts.

FPL's Medium price forecast methodology is also consistent for coal and petroleum coke prices. Coal and petroleum coke prices were based upon the following approach: (1) the price forecasts for Central Appalachian coal (CAPP), South American coal, and petroleum coke were provided by JD Energy; (2) the marine transportation rates from the loading port for coal and petroleum coke to an import terminal were also provided by JD Energy; (3) the Terminal Throughput Fee was based on a range of offers from comparable facilities throughout the Southeast U.S.. The coal price forecast for FPL's existing coal plants at SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements.

The development of FPL's Low and High price forecasts for oil, natural gas, coal, and petroleum coke prices were based upon the historical relationship of prices realized by FPL's customers compared to the average for the 2000 through 2006 time frame. FPL developed these forecasts to account for the uncertainty which exists within each commodity as well as across commodities. These forecasts reflect a range of reasonable forecast outcomes.

3. <u>Nuclear Fuel Cost Forecast</u>

This section reviews the various steps needed to fabricate nuclear fuel for delivery to the nuclear power plants, the method used to forecast the price for each step, and other comments regarding FPL's nuclear fuel costs.

a) Steps Required for Nuclear Fuel to be Delivered to FPL's Plants

Four separate steps are required before nuclear fuel can be used in a commercial nuclear power reactor. These steps are summarized below.

Step (1) - Mining: Uranium is produced in many countries such as Canada, Australia, Khazakhstan, and the United States. During the first step, uranium is mined from the ground using techniques such as open pit mine, underground mining, in-situ leaching operations, or production as a by-product from other mining operations, such as gold, copper or phosphate rocks. The product from this first step is the raw uranium delivered as an oxide, U3O8 (sometimes referred to as yellowcake).

Step (2) - Conversion: During the second step, the U3O8 is chemically converted into UF6 which, when heated, changes into a gaseous state. This second step further removes any chemical impurities and serves as preparation for the third step, which requires uranium to be in a gaseous state.

Step (3) - Enrichment: The third step is called enrichment. Natural uranium contains 0.711% of uranium at an atomic mass of 235 (U-235) and 99.289% of uranium at an atomic mass of 238 (U-238). FPL's nuclear reactors use uranium with a higher percentage of up to five percent (5%) of U-235 atoms. Because natural uranium does not contain a sufficient amount of U-235, the third step increases the percentage amount of U-235 from 0.711% to a level specified when designing the reactor core (typically in a range from approximately 3% to as high as 5%). The output of this enrichment process is enriched uranium in the form of UF6.

Step (4) - Fabrication: During the last step, fuel fabrication, the enriched UF6 is changed to a UO2 powder, pressed into pellets, and fed into tubes, which are sealed and bundled together into fuel assemblies. These fuel assemblies are then delivered to the plant site for insertion in a reactor.

Like other utilities, FPL has purchased raw uranium and the other components of the nuclear fuel cycle separately from numerous suppliers from different countries.

b) Price Forecasts for Each Step

(1) Mining: There is a significant volatility in the current uranium market. Demand is rather stable but inventory sales are a significant source of supply to complement outputs from production facilities. To the extent that source of supply can be restricted and inventories held from the market, price will rise significantly. The following are the current major contributors to this uranium price volatility:

- Hedge funds have been purchasing a significant amount of uranium, reducing availability of uranium.
- The large inventory from DOE is being withheld from the market due to political pressure.
- The Russians have announced that they would not supply down-blended weapons material to the U.S. government after 2013, for sales in the U.S. market.
- The U.S. Department of Commerce (DOC) has imposed restrictions on the import of nuclear fuel from France and Russia.

However, FPL expects these issues to be addressed within the next few years, returning price behavior to be more consistent with market fundamentals. A number of lawsuits have determined that DOC is illegally restricting the import of nuclear fuels. FPL expects the hedge funds to significantly reduce their activities, once supply starts outpacing demand. The high market price has led to significant investment to increase supply of uranium.

FPL's nuclear fuel price forecasts are the result of FPL's analysis based on inputs from various nuclear fuel market expert firms. There is a current shortage of uranium, which has pushed the current spot market price up. On the other hand, these higher market prices have motivated additional production expected to come on line over the next few years, which should bring uranium prices back to a level consistent with market fundamentals.

(2) Conversion: FPL's price forecast considers the construction of new nuclear units. Just like for raw uranium, an increase in demand for conversion services would result from this need. Insufficient planned production is currently forecast after 2013 to meet the higher demand scenario. As with additional raw uranium production, supply will expand beyond current level once more firm commitments are made to building new nuclear units.

(3) Enrichment: With no new production capacity, and if the current restrictions on imports of enrichment services from Russia and France continue, the current tight market supply for economically produced enrichment services will continue. A high projection of new nuclear unit construction shows a shortage of enrichment services, starting in 2010. Fortunately, there are a number of new facilities coming on line in that time frame and the current restrictions will be lifted, at least partially if not totally. In addition, as with supply for the other steps of the nuclear fuel cycle, expansion of future capacity is feasible within the lead time for constructing new nuclear units.

(4) Fabrication: Because the nuclear fuel fabrication process is highly regulated by the Nuclear Regulatory Commission (NRC), not all production facilities can qualify as suppliers to nuclear reactors in the U.S. Although world supply/demand is expected to show significant excess capacity for the foreseeable future, the gap is not as wide for U.S. supply and demand. The supply for the U.S. market is expected to be sufficient to meet U.S. demand for the foreseeable future.

c) Other Comments Regarding FPL's Nuclear Fuel Cost Forecast

The calculations for the nuclear fuel costs are performed consistent with the method currently used for FPL's Fuel Clause filings, including the assumption of a fuel lease and the assumption of refueling outages every 18 months. The costs for each step to fabricate the nuclear fuels are added and capitalized to come up with the total costs of the fresh fuel to be loaded at each refueling (capitalized acquisition costs). The capitalized acquisition cost for each group of fresh fuel assemblies are then amortized over the energy produced by each group of fuel assemblies, and carrying costs are also added on the total un-recovered costs to come up with the total fuel costs to be charged to customers. FPL also adds 1 mill per kilowatt hour net to reflect payment to DOE for spent fuel disposal.

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated. All values are Summer net MW.
2/ Total Capacity Available = Col.(2) + Col.(3) - Col.(4) + Col.(5).
3/ These forecasted values reflect the 2008 load forecast without DSM. This load does include load from Lee County
4/ The DSM MW shown represent cumulative load management capability plus incremental conservation from 1/2006-on for use with the 2008 load forecast. They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based.
5/ Margin (%) Before Maintenance = Col.(10) / Col.(9)
6/ Margin (%) After Maintenance = Col.(13) / Col.(9)

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All MW additions/changes occuring later in the year will be picked up for reporting/planning purposes in the following year.

Note 2: Changes shown include different ratings than shown in Schedule 1 due solely to ambient temperature consistent with those in FPL 's peak load forecast to maintain consistency in Reserve Margin calculations.

Note 3: The nuclear uprates will be performed during the scheduled refueling outages for each unit.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** West County Energy Center Combined Cycle Unit 1

(2) **Capacity**

a. Summer	1,219	MW
b. Winter	1,335	MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**

a. Field construction start-date:	2007
b. Commercial In-service date:	2009

(5) **Fuel**

a. Primary Fuel	Natural Gas
b. Alternate Fuel	Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 220 Acres

(9) **Construction Status:** U (Under construction, less than or equal to 50% complete)

(10) **Certification Status:** U (Under construction, less than or equal to 50% complete)

(11) **Status with Federal Agencies:** U (Under construction, less than or equal to 50% complete)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 90%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582	Btu/kWh (Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	25	years
Total Installed Cost (2009 $/kW):	565	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):		
Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2009 $kW-Yr)	11.65	
Variable O&M ($/MWH): (2009 $/MWH)	0.138	
K Factor:	1.5834	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** West County Energy Center Combined Cycle Unit 2

(2) **Capacity**
a. Summer 1,219 MW
b. Winter 1,335 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2008
b. Commercial In-service date: 2010

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 220 Acres

(9) **Construction Status:** U (Under construction, less than or equal to 50% complete)

(10) **Certification Status:** U (Under construction, less than or equal to 50% complete)

(11) **Status with Federal Agencies:** U (Under construction, less than or equal to 50% complete)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 88%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582	Btu/kWh (Base Operation)
Base Operation 75F,100%

Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2011 $kW-Yr)	11.63	
Variable O&M ($/MWH): (2011 $/MWH)	0.480	
K Factor:	1.4699	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** St. Lucie 1 Nuclear Uprate

(2) **Capacity**
a. Summer 103 MW (Incremental)
b. Winter 103 MW (Incremental)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2010
b. Commercial In-service date: 2011

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel ---

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	No change from existing unit
Forced Outage Factor (FOF):	No change from existing unit
Equivalent Availability Factor (EAF):	No change from existing unit
Resulting Capacity Factor (%):	No change from existing unit
Average Net Operating Heat Rate (ANOHR):	No change from existing unit
Base Operation 75F,100%	No change from existing unit

(13) **Projected Unit Financial Data** *

Book Life (Years):	25	years (Matches the current operating license period.)
Total Installed Cost ($/kW): **	3,054	(See Note (1) for explanation.)
Direct Construction Cost:	3,054	(See Note (1) for explanation.)
AFUDC Amount ($/kW):		(See Note (2) for explanation.)
Escalation ($/kW):		(See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.):	There is no additional O&M impact from this project.	
Variable O&M ($/MWH):	There is no additional O&M impact from this project.	
K Factor:		(See Note (2) for explanation.)

NOTE:
(1) This value does not include a plant-specific portion of the early recovery of approx. $353 million of capital carrying costs in total associated with the uprates at the four existing nuclear units, nor a plant-specific portion of a projected $45 million in total for transmission costs associated with the uprates at the four existing nuclear units.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

* $/kW values are based on incremental Summer capacity.
** $/incremental kW

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

Note:
(1) FPL Existing Units Total matches Total System found on Schedule 1.
(2) Net Energy for Load MWH matches Schedule 6.1

Schedule 11.2

Existing NON-FIRM Self-Service Renewable Generation Facilities
Actuals for the Year 2007

(1)	(2)	(3)	(4)	(5) = (3) - (4)
Type of Facility	**Installed Capacity (MW)**	**Projected Annual Output (MWH)**	**Annual Energy Sold to FPL (MWH)**	**Projected Annual Energy Used by Customer (MWH)**
Customer-Owned PV (less than 10 kw)	0.27	277.19	57.59	219.60

Notes:

(1) There were approximately 110 customer-owned operating PV facilities interconnected with FPL during this year.
(2) The Installed Capacity value is the sum of the nameplate ratings (AC kw) for all of the customer-owned PV facilities.
(3) The Projected Annual Output value is based on NREL's PV Watts program and the Installed Capacity value in column (2), adjusted for the date when each facility was installed and assuming each facility operated as planned.
(4) The Annual Energy Sold to FPL is an actual value from FPL's metered data for this year.
(5) The Projected Annual Energy Used by Customers is a projected value that is the difference between the Projected Annual Output value in column (2) and the actual Annual Energy Sold to FPL in column (4).

(This page is left intentionally blank.)

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in FPL's service area is continuing, which heightens competition for air, land, and water resources that are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among electric utilities for its commitment to the environment. FPL's environmental leadership has been heralded by many outside organizations as demonstrated by a few recent examples. In 2004, FPL Group earned a first place ranking among U.S. power companies and second globally in a report from the World Wildlife Fund for voluntary commitments to limit CO_2 emissions. This commitment was made to support initiatives to better manage utility impacts on climate change through use of greenhouse gas emission reductions and improvements in energy efficiency. The report stated that this was "primarily due to the company's leadership in developing wind energy and their commitment to dramatically improve their efficiency." In January 2007, FPL joined with a diverse group of U.S.-based business market leaders and leading non-governmental organizations to form the U.S. Climate Action Partnership (USCAP) in recognition of the need for a national policy framework on climate change. USCAP has called upon the federal government to formulate mandatory economy-wide policies to reduce CO_2 emissions.

As a further demonstration of FPL's efforts in sustainability, the EPA and the Department of Energy gave an award to FPL for its Sunshine Energy® program which allows customers, who voluntarily choose to participate, to pay a premium for their electricity that is used to purchase renewable energy credits associated with electric energy generated from renewable energy sources. FPL Group, the parent corporation of FPL was also recently awarded its fourth number one rating of major electric utilities surveyed in an environmental assessment conducted by Innovest, an independent advisory group. This rating was in recognition of FPL Group's success in executing a strategy to become a clean energy provider harnessing primarily clean and renewable fuels while also boosting shareholder value. FPL Group was named one of the world's most Sustainable

Corporations in Global 100 and was one of only two utilities to be so named in the United States.

FPL has also been the recipient of earlier environmental awards and recognition. In 2001, FPL was awarded Edison Electric Institute's National Land Management Award for its stewardship of 25,000 acres surrounding its Turkey Point Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. FPL received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" in 2001 for its emission-reducing "repowering" projects at its Fort Myers and Sanford Plants. FPL won the Council for Sustainable Florida's award in 2002 for its sea turtle conservation and education programs at its St. Lucie Plant. Finally, FPL has been recognized by numerous federal and state agencies for its innovative endangered species protection programs which include such species as manatees, crocodiles, and sea turtles.

As mentioned above, FPL Group has taken a leadership role to address climate change and the call for action for a national climate change policy. The decision to step into the forefront of this issue goes hang-in-hand with FPL Group's longtime commitment to managing operations with sensitivity to the environment.

FPL is taking action now in Florida to address climate change with a number of actions. According to the U.S. Department of Energy (DOE), FPL is the nation's leader among electric utilities for its energy efficiency/conservation achievement and is also ranked number three nationally in load management achievement. FPL's nationally recognized leadership in the implementation of demand side management (DSM) within its system has avoided the need to build the equivalent of 12 medium-sized power plants as discussed in Chapter III of this document. Also discussed in Chapter III are FPL's plans for adding a significant amount of renewable energy resources. FPL is also the nation's leader in "repowering," significantly increasing the efficiency of a number of its existing power plants while reducing FPL system emissions. In addition, FPL's future generation plans include nuclear uprates and two new nuclear units that are projected to significantly reduce air emissions in Florida.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define its position. This statement reflects how FPL incorporates environmental values into all aspects of its activities and serves as a framework for new environmental initiatives throughout the company. FPL's Environmental Statement is:

It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:

- Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
- Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
- Encourage the wise use of energy to minimize the impact on the environment.
- Communicate effectively on environmental issues.
- Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, a dedicated environmental corporate governance program, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident and/or emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with corporate policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and FPL policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2006 environmental outreach activities are noted in Table IV.E.1.

Table IV.E.1: 2007 FPL Environmental Outreach Activities

Activity	***# of Participants***
Visitors to Energy Encounter	20,000
Visitors to Manatee Park	150,000
Number of visits to FPL's Environmental Website	300,000
Number of pieces of Environmental literature distributed	>120,000

(All numbers are approximations.)

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified three Preferred Sites and eight Potential Sites for future generation additions. Preferred Sites are those locations where FPL has conducted significant reviews and has either taken action, or is planning to take action, to site new generation capacity. Potential Sites are those sites that have attributes that support the siting of generation and are under consideration as a location for future generation. Some of these sites are currently in use as existing generation sites and some are not. The identification of a Potential Site does not indicate that FPL has made a definitive decision to pursue generation (or generation expansion in the case of an existing generation site) at that location, nor does this designation indicate that the size or technology of a generator has been determined. The Preferred Sites and Potential Sites are discussed in separate sections below.

IV.F.1 Preferred Sites

FPL identifies three Preferred Sites in this Site Plan: the West County Energy Center (WCEC) adjacent to the existing Corbett FPL substation, the existing St. Lucie plant site, and the existing Turkey Point plant site. The West County Energy Center site is the location for combined cycle capacity additions FPL will make in 2009 and 2010, and is proposing to make in 2011. The St. Lucie site is the location for nuclear capacity additions that FPL will make in 2011 and 2012, and the plant site is also the location for a proposed wind generation addition that is proposed for 2009. The Turkey Point site is the location for nuclear capacity additions that FPL will make in 2012.

In regard to the WCEC site, combined cycle (CC) capacity additions, WCEC units 1 & 2, have been approved by the FPSC and by the Governor and Cabinet acting as the Siting Board. FPL is planning to file a need petition for the WCEC unit 3 combined cycle unit in April 2008.

In regard to the St. Lucie and Turkey Point sites, FPL petitioned the FPSC for approval of capacity uprates for the two existing nuclear units at each of these sites in September 2007. The FPSC approved the need and issued a Need Order for both Uprates in January 2008.

The existing Turkey Point plant site is also the proposed site for two new nuclear units, Turkey Point units 6 & 7. These two new nuclear units are proposed for 2018 and 2020, respectively. FPL filed for approval of a determination of need for these two new nuclear units with the FPSC in the second half of 2007. The FPSC voted to approve this request on March 18, 2008, and is expected to issue a final order approving the units in April 2008. These new nuclear units are not discussed in detail in this Site Plan because the units' projected in-service dates, fall outside of the 2008-2017 time period covered in this document.

The three Preferred Sites are discussed below.

Preferred Site # 1: West County Energy Center , Palm Beach County

FPL has identified the property adjacent to the existing Corbett Substation property in unincorporated western Palm Beach County as a Preferred Site for the addition of new generating capacity. The site was selected for the addition of two new combined cycle natural gas power plants with ultra-low sulfur light fuel oil (distillate) as a backup fuel. These units, WCEC 1 & 2, have been approved by both the FPSC and the Governor and Cabinet acting as the Siting Board. The units are scheduled to come in-service in 2009 and 2010, respectively. In addition, the site has also been selected as the location for a proposed third combined cycle unit, WCEC 3, projected to come in-service in 2011 if approved. FPL plans to file for FPSC approval of a determination of need for this unit in April 2008. If approved, all three combined cycle units will be identical in regard to technology and capacity.

The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections. The approved and proposed facilities would use natural gas as the primary fuel and state-of-the-art combustion controls.

a. U.S. Geological Survey (USGS) Map

A USGS map of the West County Energy Center (WCEC) plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the WCEC generating facilities at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The site was inactive until February 2007 when construction of WCEC 1 & 2 was initiated. The site was previously dedicated to industrial and agricultural use. The site had been excavated, back-filled, and totally re-graded to an elevation approximately 10 feet. above the surrounding land surface. Prior to initiation of power plant construction, no structures were present on the site and vegetation was virtually non-existent. Structures are now being built on the site for work associated with WCEC 1 & 2.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The plant site had been significantly altered by the construction and operation of a limestone mine where vegetation had been cleared and removed. The surrounding land use is predominantly sugar cane agriculture and limestone mining. FPL's existing Corbett substation is located north of the site. The Arthur R. Marshall Loxahatchee National Wildlife Refuge is located to the south of the site.

2. Listed Species

Construction and operation of new units at the site is not expected to affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the prior mining activities. Common wading birds can be observed on areas adjacent to, and occasionally within, the property. The property is adjacent to areas that have been identified as potential habitat for wood stork.

3. Natural Resources of Regional Significance Status

The construction and operation of gas-fired combined cycle generating facilities at this location are not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands including the Arthur R. Marshall Loxahatchee National Wildlife Refuge. Construction will not result in any onsite wetland impacts under federal, state, or local agency permitting criteria.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design of both the two approved units and the one proposed unit is a new 1,219 MW (Summer capacity) unit with each unit consisting of three new combustion turbines (CT) and three new heat recovery steam generators (HRSG) and a new steam turbine. Natural gas delivered via pipeline is the primary fuel type for this facility with ultra-low sulfur light fuel oil (distillate) serving as a backup fuel.

g. Local Government Future Land Use Designations

Local government future land use designation for the project site is "Rural Residential" according to the Palm Beach County Future Land Use Map. Designations for the area under the Palm Beach County Unified Land Development Code classified the project site and surrounding area as Special Agricultural District. The site has been granted conditional use for electrical power facilities under a General Industrial zoning district.

h. Site Selection Criteria Process

The site has been selected as a Preferred Site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues.

i. Water Resources

In regard to the two approved units, water from the Floridan Aquifer and surface water from the L10/L12 canal will be used for cooling, service, and process water. Water from the surficial aquifer will be treated and used for potable water unless water is available for purchase from Palm Beach County water municipality.

In regard to the proposed third unit, the primary water source for the project will be reclaimed (reuse) water that will come from Palm Beach County Water Utilities Department. FPL will obtain the necessary approvals to also supply Units 1 & 2 using reclaimed water after obtaining the necessary approvals for Unit 3. The Floridan and L10/L12 will remain as back up water supplies for the site. Reclaimed water will be used for cooling, service, and process water. Back-up water sources include utilizing the Floridan Aquifer allocation permitted for WCEC 1 & 2, potable water from Palm Beach County, and the L10/L12 canal when made available by the SFWMD. Water from the surficial aquifer will be treated and used for potable water unless water is available for purchase from Palm Beach County.

j. Geological Features of Site and Adjacent Areas

The site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, clay, and phosphate grains. The deepest formation in Palm Beach County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Oldsmar formation. The published information on the sediments comprising the formations below the Avon Park Limestone is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach Counties.

Testing during construction of Exploratory Well 2 (EW-2) demonstrated the presence of a highly permeable zone (Boulder Zone) below a depth of 2,790 feet below pad level (bpl) overlain by a thick confining interval from approximately 2,000 to 2,790 feet bpl. The base of the Underground Source of Drinking Water (USDW) was identified between the depths of 1,932 and 1,959 feet bpl through interpretation of packer tests water quality data and geophysical logs. These conditions suggest that the hydrogeology of the EW-2 site is favorable for disposal of fluids via a deep injection well system.

k. Projected Water Quantities for Various Uses

In regard to the two approved units, the estimated quantity of water required for industrial processing for both units is approximately 450 gallons per minute (gpm) for uses such as process water and service water. Approximately 15 million gallons per day (mgd) in total of cooling water for the two generating units would be cycled through the addition of cooling towers.

In regard to the proposed third unit, the estimated quantity of water required for industrial processing is approximately 225 gallons per minute (gpm) for uses such as process water and service water. Approximately 7.5 million gallons per day (mgd) in total of cooling water for the one generating unit would be cycled through the addition of a cooling tower. Water quantities needed for other uses such as potable water are estimated to be approximately 35,000 gallons per day (gpd) for the entire WCEC site.

l. Water Supply Sources by Type

The two approved generating units will use available surface or ground water as the source of cooling water for the cooling towers. The cooling towers will also act as a heat sink for the facility process water. Such needs for cooling and process water will comply with the existing South Florida Water Management District (SFWMD) regulations for consumptive water use.

In regard to the proposed third unit, it will use reclaimed water as the primary source of cooling water for the cooling tower. The cooling tower will also act as a heat sink for the facility process water. Such needs for cooling and process water will comply with the existing SFWMD regulations for consumptive water use. In addition, reclaimed water used by WCEC 3 must meet all relevant requirements of Chapter 62-610, F.A.C., Part III, for use in the cooling tower.

m. **Water Conservation Strategies Under Consideration**

The use of reclaimed water is a water conservation strategy because it is a beneficial use of wastewater. Impacts on the surficial aquifer would be minimized and used only for potable water. Water from the Floridan Aquifer or the L10/L12 canal will be used for cooling purposes as a backup water source and cooling towers will be utilized. In addition, captured stormwater will be reused in the cooling tower whenever feasible. Stormwater captured in the stormwater ponds will also recharge the surficial aquifer.

n. **Water Discharges and Pollution Control**

Heat will be dissipated in the cooling towers. Blowdown water from the cooling towers, along with other wastestreams, will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. In addition, captured stormwater will be reused in the cooling towers whenever feasible The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. **Fuel Delivery, Storage, Waste Disposal, and Pollution Control**

The site is not located near an existing natural gas transmission pipeline that is capable of providing a sufficient quantity of gas. Upgrades of existing pipelines and/or lateral connections to other pipelines will be made for supply of natural gas. Ultra-low sulfur light fuel oil (distillate) would be received by truck and stored in above-ground storage tanks to serve as backup fuel for the new units.

p. **Air Emissions and Control Systems**

The use of natural gas and ultra-low sulfur light fuel oil (distillate) and combustion controls will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil (distillate) as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the West County Energy Center units will incorporate features that will make them among the most efficient and cleanest power plants in the State of Florida.

q. **Noise Emissions and Control Systems**

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site. Noise from the operation of the new units will be within allowable levels.

r. **Status of Applications**

In regard to the two approved units, a Site Certification Application (SCA) for the construction and operation of the West County Energy Center project under the Florida Electrical Power Plant Siting Act was filed on April 14, 2005 and received Site Certification by the Governor and Cabinet, acting as the Siting Board, on December 26, 2006. Palm Beach County Planning Zoning and Building department issued approval for the project on June 28, 2006. FDEP issued an Underground Injection Control Exploratory Well permit on January 11, 2006 and another Exploratory Well Permit on December 6, 2006. FDEP issued a Prevention of Significant Deterioration (PSD) air permit on January 10, 2007. After acquiring these permits and authorizations, FPL initiated construction in February 2007 and anticipates an in-service date for the first unit of mid-2009. FDEP is in the process of issuing the Final UIC permit.

In regard to the proposed third unit, a Site Certification Application (SCA) for the construction and operation of WCEC 3 under the Florida Electrical Power Plant Siting Act was filed on December 6, 2007 and is currently undergoing review. Palm Beach County Planning Zoning and Building department issued initial approval on November 29, 2007, and final approval on December 5, 2007, for an increase in total generating capacity for the project. A Prevention of Significant Deterioration (PSD) air permit was filed on December 6, 2007. After acquiring these permits and authorizations, FPL proposes to initiate construction in June 2009 and anticipates an in-service date of mid-2011. WCEC 3 plans to utilize the UIC system being permitted for the entire site.

Preferred Site # 2: St. Lucie Plant, St. Lucie County

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The plant site is bordered by the Atlantic Ocean to the east and the Indian River Lagoon to the west. Located on the site are two nuclear powered generating units, St. Lucie Units 1 & 2, that have been in operation since 1976 and 1983, respectively. The St. Lucie site has been selected as a Preferred Site for the addition of two types of new generating capacity.

The first type of generating capacity addition is an increase in the capacity of the two existing nuclear generating units by approximately 103 to 104 MW each. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new or expanded facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing Turkey Point nuclear units, was approved by the FPSC in January 2008. The capacity uprates at St. Lucie for the two nuclear units sited there are projected to be in-service in late 2011 and 2012, respectively.

The second type of generating capacity addition is the proposed installation of FPL wind generation turbines at the plant site by 2009. Six wind turbines are being proposed that, in total, would have a maximum output of approximately 13.8 MW.

a. U.S. Geological Survey (USGS) Map

A USGS map of the FPL St. Lucie Nuclear site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the proposed generating facilities at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

St. Lucie Units 1 & 2 are pressurized water reactors, each having two steam generators. The prominent structures, enclosed facilities, and equipment associated with St. Lucie Units 1 & 2 include the containment building, the turbine generator building, the auxiliary building, and the fuel handling building.

Prominent features beyond the power block area include the intake and discharge canals, switchyard, spent-fuel storage facilities, technical and administrative support facilities, and public education facilities (Energy Encounter Exhibit and the Marine Education Facility). Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay and Indian River Lagoon.

In regard to the nuclear capacity uprates, the only changes will be modifications to the existing power generation facilities within the power block area. None of the other existing facilities at the plant will change as a result of the uprates. No changes to the nuclear power generation facilities are currently projected as a result of the proposed wind turbine additions.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The St. Lucie Plant includes the reactor buildings, turbine buildings, access/security building, auxiliary building, maintenance facilities, and miscellaneous warehouses and other buildings associated with the operation of Units 1 & 2. The site includes adjacent undeveloped mangrove areas. As a result of the approved capacity uprates, the site characteristics will not change.

The proposed wind turbines are also located on the FPL-owned site. Impacts to the site characteristics are projected to be minimal from the proposed wind turbines.

2. **Listed Species**

Some listed species known to occur in the area of the plant location are atlantic sturgeon, smalltooth sawfish, loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas)*, leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtle (*Eretmochelys imbriccata*), gopher tortoise (*Gopherus polyphemus*), kemp's ridley (*Lepidochelys kempi*) sea turtle, wood stork (*Mycteria americana*), black skimmer (*Rynchops niger*), and least tern (*Sterna antillarum*).

In regard to the capacity uprates, neither the development work, nor the continued operation of the two nuclear units after the uprate work has been completed, are expected to adversely affect any rare, endangered, or threatened species. No changes in wildlife populations at the adjacent undeveloped areas are anticipated, including listed species. Noise and lighting impacts will not change and it is expected that wildlife will continue to use the undeveloped areas within the St. Lucie Plant boundary.

In regard to the wind turbines, some changes to the adjacent undeveloped areas are anticipated, excluding listed species. Noise and lighting impacts will not change and the wind turbines are not anticipated to deter the continued use by wildlife of the undeveloped areas within the St. Lucie Plant boundary or any adjacent areas.

3. **Natural Resources of Regional Significance Status**

Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay and Indian River Lagoon.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. It is a once-through system. The effects of the discharge of cooling water via these discharge structures were evaluated and mixing zones were established to allow compliance with thermal water quality standards as a part of the Plant's NPDES (Permit No. FL0002208). These mixing zones include the volume of water beyond the discharge structures, at the edge of which, the water temperature is no greater than 17°F above the ambient temperature of the intake water.

In regard to the nuclear capacity uprates, the once-through system will continue to be used for the nuclear units. In regard to the wind turbines, no water will be used.

g. <u>Local Government Future Land Use Designations</u>

St. Lucie Units 1 & 2 are located in unincorporated St. Lucie County, Florida. The County has adopted a comprehensive plan, which is updated on a periodic basis. The County Comprehensive Plan incorporates a map that depicts the future land use categories of all property falling within the unincorporated portions of the County. The St. Lucie Plant has a Future Land Use category of Transportation/Utilities (T/U) according to the St. Lucie County Future Land Use Map. The T/U category is described in the St. Lucie County Comprehensive Plan Future Land Use Element Future Land Use.

h. <u>Site Selection Criteria Process</u>

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity. The site has been selected as a Preferred Site for the wind turbines because of the available wind resource at that location.

i. <u>Water Resources</u>

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. The once-through system flow will not change as a result of the nuclear capacity uprates. There will be no water used to operate the wind turbines. Due to the existing nature of the St. Lucie Plant, surrounding surface waters will not be adversely affected by either of the generation capacity additions. Stormwater will be handled by the existing facilities and no new areas will be impacted. Wetlands, groundwater, and nearby surface waters will not be impacted.

j. <u>Geological Features of Site and Adjacent Areas</u>

Beneath the land surface, there is a peat layer 4 to 6 feet thick. Below this layer is the Anastasia Formation, a sedimentary rock formation composed of clay lenses, sandy limestone, and silty fine to medium sand with fragmented shells. This highly permeable stratum extends 35 to 90 feet below mean sea level (msl). Underlying this stratum there is a semi-permeable zone, The Hawthorn Formation, consisting of slightly clayey and very fine silt which extends 600 feet below msl.

The original surficial deposits at the St. Lucie Plant were excavated to a depth of 60 feet and backfilled with Category I or II fill. The fill is underlain by the Anastasia formation, a sequence of partially cemented sand and sandy limestone, which extend to an average depth of about 145 feet. The Anastasia is underlain to an depth of about 600 to 700 feet by the partially cemented and indurated sands, clays, and sandy limestones of The Hawthorn Formation. Underlying these surface strata are about 13,000 feet of Jurassic through Tertiary Formations, primarily carbonate rocks. These formations have a relatively gentle slope to the southeast.

k. Projected Water Quantities for Various Uses

In regard to the nuclear capacity uprates, no change is expected in the quantity or characteristics of industrial wastewaters generated by the facility. Therefore, no change in that compliance achievement status is expected. The capacity uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The St. Lucie Plant does not directly withdraw groundwater under its current operations and it will not withdraw groundwater after the uprates work is completed. The use of water supplied by the City of Fort Pierce, which does withdraw groundwater, will remain unchanged and there will be no changes to the groundwater discharges. There will be no quality, quantity, or hydrological changes, either by withdrawal or discharge to a drinking water source. Therefore, there will be no impacts on drinking water.

The wind turbines will not require water for operations and will not cause any changes in the hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow.

l. Water Supply Sources by Type

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. General plant service water, fire protection water, process water, and potable water are obtained from City of Fort Pierce. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns.

The existing St. Lucie Plant water use is projected to be unchanged from that for the existing facility as a result of the nuclear capacity uprates. The wind turbines will not require water for operations.

m. Water Conservation Strategies Under Consideration

The existing water resources will not change as a result of the nuclear capacity uprates. The wind turbines will not require water for operations.

n. Water Discharges and Pollution Control

St. Lucie Units 1 & 2 use once-through cooling water from the Atlantic Ocean to remove heat from the main (turbine) condensers via the Circulating Water System (CWS), and to remove heat from other auxiliary equipment via the Auxiliary Equipment Cooling Water System (AECWS). The great majority of this cooling water is used for the CWS.

Under emergency conditions, water can be withdrawn from Big Mud Creek via the Emergency Intake Canal through two 54-inch pipe assemblies in the barrier wall that separates the Creek from the Canal. FPL does not use this intake during normal operations, but does test this system semi-annually.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

The wind turbines will not require water for operations. Consequently, there will be no water discharge as a result of these turbines.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

St. Lucie Units 1 & 2 are licensed for uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core. Each reactor core includes 217 fuel assemblies.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 47,000 megawatt-days per metric ton uranium. In regard to the nuclear capacity uprates, more nuclear fuel will be used due to the increased capacity of each unit. No changes in the fuel-handling facilities are required. The addition of the wind turbines will have no fuel-related impact; i.e., no impacts from fuel delivery, storage, waste, or pollution control.

Diesel fuel is used in a number of emergency generators that include four main plant generators, two building generators, and various general purpose diesel engines. The main plant emergency generators will not be changed as a result of either of the two types of generation capacity additions. These emergency generators are for standby use only and only tested to assure reliability and for maintenance. Diesel fuel is delivered to the St. Lucie Plant by truck as needed, and stored in tanks with secondary containment.

p. Air Emissions and Control Systems

The St. Lucie Plant is classified as a minor source of air pollution, since FDEP has issued a Federally Enforceable State Operating Permit (FESOP) to keep emissions less than 100 tons per year for any air pollutant regulated under the Clean Air Act.

The applicable units at the St. Lucie Plant in regard to air emissions consist of eight large main plant diesel engines, two smaller diesel engines, and various general-purpose diesel engines. The air emissions from these engines are limited by the use of 0.05-percent sulfur diesel fuel and good combustion practices. Best Available Control Technology (BACT) is not applicable to these existing emission units.

Nitrogen oxide (NOx) emissions from the operation of the diesel engines comprise the limiting pollutant for these diesel units at the St Lucie Plant. The FDEP FESOP limits NOx emissions to 99.4 tons, which includes fuel use limits on the large main plant emergency diesel engines of 97,000 gallons in any 12-month consecutive period and the smaller building and general purpose diesel engines of 190,000 gallons in any 12-month consecutive period. Also, the Plant may choose to combine the diesel units' fuel-tracking, which then limits the NOx totals for a 12-month consecutive period to a maximum of 80 tons. There will be no change in the operation or emissions of the diesel engines resulting from either the nuclear capacity uprates or the wind turbines. In addition, neither of these types of generation capacity additions will result in an increase of carbon dioxide (CO_2) or other greenhouse gas emissions. In fact, both of these increases in generation capacity are projected to result in decreased FPL system emissions of CO_2 and other greenhouse gases.

q. Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by construction activities at the site was conducted in regard to both types of generation capacity additions. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site during construction or operation of either generating capacity additions.

r. Status of Applications

In regard to the nuclear capacity uprates, a Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed on December 13, 2007. The FPSC voted to approve the need for the St. Lucie (and Turkey Point) uprates and the final order approving the need for these units was issued on January 7, 2008. In regard to the wind turbines, a Site Certification Application is not required.

Preferred Site # 3: Turkey Point Plant, Miami-Dade County

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear units (Units 3 & 4) and two natural gas/oil conventional boiler units (Units 1 & 2), one combined cycle natural gas unit (Unit 5), the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the Everglades Mitigation Bank (EMB).

Turkey Point Units 3 & 4 have been in operation since 1972 and 1973, respectively. The Turkey Point site has been selected as a Preferred Site for the increase in the capacity of its two existing nuclear generating units by approximately 103 to 104 MW each. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new or expanded facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing St. Lucie nuclear units, was approved by the FPSC in January 2008. The capacity uprates at Turkey Point are projected to be in-service in 2012.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Turkey Point plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the Turkey Point Units 3 & 4 generating facility at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The five existing power generation units and support facilities occupy approximately 150 acres of the 11,000-acre Turkey Point Plant. Support facilities include service buildings, an administration building, fuel oil tanks, water treatment facilities, circulating water intake and outfall structures, wastewater treatment basins, and a system substation. The cooling canal system occupies approximately 5,900 acres. The two 400-megawatt (MW) (nominal) fossil fuel-fired steam electric generation units at the Turkey Point Plant have been in service since 1967 (Unit 1) and 1968 (Unit 2). These units currently burn residual fuel oil and/or natural gas with a maximum equivalent sulfur content of 1 percent. The two 700-MW (nominal) nuclear units have been in service since 1972 (Unit 3) and 1973 (Unit 4). Turkey Point Units 3 & 4 are pressurized water reactor (PWR) units. Turkey Point Unit 5 is a nominal 1,150-MW combined cycle unit that began operation in 2007. Significant features in the vicinity of the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The prominent structures and enclosed facilities and equipment associated with Units 3 & 4 include: the containment building, which contains the nuclear steam supply system, including the reactor, steam generators, reactor coolant pumps, and related equipment; the turbine generator building, where the turbine generator and associated main condensers are located; the auxiliary building, which contains waste management facilities, engineered safety components, and other facilities; and the fuel handling building, where the spent fuel storage pool and storage facilities for new fuel are located. Prominent features beyond the power block area include the intake system, cooling canal system, switchyard, spent fuel storage facilities, and technical and administrative support facilities.

2. **Listed Species**

The construction during the uprating of the units, and operation of the units after the capacity uprating is completed, are not expected to adversely affect any rare, endangered, or threatened species. Listed species known to occur in the nearby Biscayne National Park that could potentially utilize the site include the peregrine falcon *(Falco peregrinus)*, wood stork *(Mycteria americana)*, American crocodile *(Crocodylus acutus)*, mangrove rivulus *(Rivulus marmoratus)*, roseate spoonbill *(Ajaja ajaja)*, limpkin *(Aramus guarauna),* little blue heron *(Egretta caerulea),* snowy egret *(Egretta thula),* American oystercatcher *(Haematopus palliates),* least tern *(Sterna antillarum)*, the white ibis *(Eudocimus albus)*, and bald eagle *(Haliaeetus leucocephalus)*. No bald eagle nests are known to exist in the vicinity of the site. The federally listed, endangered American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American crocodile.

3. **Natural Resources of Regional Significance Status**

Significant features in the vicinity on the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park. Biscayne National Park contains 180,000 acres, approximately 95% of which is open water interspersed with over 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant and is adjacent to the Miami-Dade County Homestead Bayfront Park which contains a marina and day use recreational facilities.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

Turkey Point Units 3 & 4 uses cooling water from a closed-cycle cooling canal system to remove heat from the main (turbine) condensers, and to remove heat from other auxiliary equipment. The existing cooling canals will accommodate the increase in heat load that is associated with the increased capacity from the uprates. The maximum predicted increase in water temperature entering the cooling canal system from the units resulting from the uprates is predicted to be about 2.5°F, from 106.1 to 108.6°F. The associated maximum increase in water temperature returning to the units is about 0.9°F, from 91.9 to 92.8°F.

g. <u>Local Government future Land Use Designations</u>

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. <u>Site Selection Criteria Process</u>

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity.

i. <u>Water Resources</u>

Unique to Turkey Point plant site is the self-contained cooling canal system that supplies water to condense steam used by the plant's turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide, and approximately four feet deep. The system performs the same function as a giant radiator. The water is circulated through the canals in a two-day journey, ending at the plant's intake pumps.

j. <u>Geological Features of Site and Adjacent Areas</u>

The Turkey Point Plant lies upon the Floridian Plateau, a partly-submerged peninsula of the continental shelf. The peninsula is underlain by approximately 4,000 to 15,000 feet of sedimentary rocks consisting of limestone and associated formations that range in age from Paleozoic to Recent. Little is known about the basement complex of Paleozoic igneous and metamorphic rocks due to their great depth.

Generally in Miami-Dade County, the surficial aquifer (Biscayne Aquifer) consists of a wedge-shaped system of porous clastic and carbonate sedimentary materials, primarily limestone and sand deposits of the Miocene to late Quaternary age. The Biscayne Aquifer is thickest along the eastern coast and varies in thickness from 80 to 200 feet thick. The surficial aquifer is typically composed of Pamlico Sand, Miami Limestone (Oolite), the Fort Thompson and Anastasia Formations (lateral equivalents), Caloosahatchee Marl, and the Tamiami formation. The lower confining layers below the surficial aquifer range in thickness from 350 to 600 feet and are composed of the Hawthorn Group. Beneath the Hawthorn Group, the Floridan Aquifer System (FAS) ranges from 2,800 to 3,400 feet thick and consists of Suwannee Limestone, Avon Park Limestone, and the Oldsmar Formations.

k. Projected Water Quantities for Various

The addition of nuclear generating capacity as a result of the uprates will not cause any changes in the quantity or characteristics of industrial wastewaters generated by the facility; therefore, no change in that compliance achievement status is expected. The uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The Turkey Point Plant does not directly withdraw groundwater under its current operations and it will not do so after the capacity uprates. Locally, groundwater is present beneath the Site in the surficial or Biscayne Aquifer and in deeper aquifer zones that are part of the Floridan Aquifer System. There will be no effects on those deeper aquifer zones from the capacity uprates.

l. Water Supply Sources and Type

The source of cooling water for Turkey Point Units 3 & 4 is the cooling canal system. There will be no increase in the amount of water withdrawn as a result of the capacity uprates. General plant service water, fire protection water, process water, and potable water are obtained from Miami-Dade County. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns. The water use for the facility will not change as a result of the capacity uprates.

m. Water Conservation Strategies

The existing water resources will not change as a result of the uprates.

n. Water Discharges and Pollution Control

Heated water discharges are dissipated using the existing closed cooling water system and the cooling canal system.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Turkey Point Units 3 & 4 utilize uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 45,000 megawatt-days per metric ton of uranium. Following completion of the uprates, more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel handling facilities are required.

Diesel fuel is used in a number of emergency generators that include four main emergency generators, five smaller emergency generators and various general purpose diesel engines. The emergency generators will not be changed as a result of the capacity uprates. These emergency generators are for stand-by use only and only operated for testing purposes to assure reliability and for maintenance. Diesel fuel for the emergency generators is delivered to the Turkey Point Plant by truck as needed, and stored in tanks with secondary containment.

p. Air Emissions and Control Systems

The normal operation of Turkey Point Units 3 & 4 does not create fossil fuel-related air emissions. However, there are nine emergency generators associated with Units 3 & 4. Four main plant emergency generators are rated at 2.5 MW. Five smaller emergency generators are associated with the security system. In addition, various general purpose diesel are used as needed for Units 3 & 4.

Turkey Point Plant Units 3 & 4's associated emergency generators and diesel engines, together with Units 1, 2, and 5, are classified as a major source of air pollution. FDEP has issued a separate Title V Air Operating Permit for the Turkey Point Nuclear Plant (Permit Number 0250003-004-AV). There are no operating limits for the emergency generators or diesel engines. NOx emissions are regulated under Reasonably Available Control Technology (RACT) requirements in Rule 62-296.570(4)(b)7 F.A.C., which limit NOx emissions to 4.75 lb/MMBtu. The use of 0.5 percent sulfur diesel fuel and good combustion practices serve to keep NOx emissions under this limit.

q. Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by activities associated with the uprates was conducted. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site..

r. Status of Applications

A Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed on January 18, 2008. The FPSC voted to approve the need for the Turkey Point (and St. Lucie) uprates and the final order approving the need for these units was issued on January 7, 2008.

IV.F.2 Potential Sites for Generating Options

Eight (8) sites are currently identified as Potential Sites for near-term future generation additions to meet FPL's capacity and energy needs[2]. These sites have been identified as Potential Sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these Potential Sites offer a range of considerations relative to engineering and/or costs associated with the construction and operation of feasible technologies. In addition, each Potential Site has different characteristics that will require further definition and attention. Solely for the purpose of estimating water requirements for each site, it was assumed that either one dual-fuel (natural gas and light oil) simple cycle combustion turbine (CT) or a natural gas-fired combined cycle unit (CC) would be constructed at the Potential Sites. A simple cycle CT would require approximately 50 gallons per minute (gpm) for both process and cooling water (assuming air cooling). A CC unit would require approximately 150 gpm for service and process water and approximately 14 million gallons per day (mgd) for cooling water depending upon the water source and associated water quality. If an existing power plant site is ultimately selected for repowering of an existing unit(s), the water requirements discussed above for a CC unit would be approximately correct for the repowered unit. If a renewable energy generating

[2] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites and other greenfield sites.

technology, such as photovoltaic and solar thermal, is ultimately selected for one of these sites, the water requirements would be less than those for CT or CC facilities.

Permits are presently considered to be obtainable for each of these sites. No significant environmental constraints are currently known for any of these sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time FPL considers each site to be equally viable.

Potential Site # 1: West Broward, Broward County

FPL has identified the Andytown Substation property in western unincorporated Broward County as a potential site for the addition of new generating capacity and FPL refers to this potential site as the West Broward site. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site has been included at the end of this chapter.

b. **Land Uses**

The land uses for the potential site were designated as agricultural use.

c. **Environmental Features**

Extensive low-quality wetlands are present on the site. Construction and operation of a new facility on this site would not be expected to adversely affect any rare, endangered, or threatened species.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Groundwater from the shallow aquifer or a local source of reclaimed (reuse) water has been identified as potential water sources. The Floridan Aquifer has also been identified as a potential cooling water source.

Potential Site # 2: Cape Canaveral Plant, Brevard County

The FPL Cape Canaveral Plant property is located in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway (U.S. 1). A rail line is located near the plant. The existing facility consists of two 400 MW (approximate) steam boiler type generating units.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site is found at the end of this chapter.

b. Land Uses

The land is primarily dedicated to industrial use; i.e., FPL's existing Cape Canaveral power plant Units 1 & 2. It is surrounded by grassy areas and a few acres of remnant pine forest. The land adjacent to the site is dedicated to light commercial and residential use.

c. Environmental Features

The site is located on the Intra-coastal waterway which provides warm water refugia for manatees during cold winter days.

d. Water Quantities

As previously discussed, if additional water is needed beyond the currently permitted amount, then the water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Existing on-site wells, reclaimed (reuse) water, public supply water, and the existing once-through cooling water system are potential water supply sources.

Potential Site # 3: Desoto County Greenfield Site

This site is a "Greenfield" undeveloped site located on a 13,515 acre property in unincorporated Desoto County. The site is adjacent to portions of the Peace River and lies on both the east and west sides of U.S. Highway 17 approximately 3 to 5 miles north of the City of Arcadia. There are currently no utility facilities on the site.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site is found at the end of this chapter.

b. Land Uses

A portion of the land on the site is currently dedicated to agricultural use (sod farming, cattle grazing, and truck crops). The remaining land is undeveloped.

c. Environmental Features

Developed portions of the adjacent properties are primarily agricultural (sod farms, citrus groves, and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and a few small isolated wetlands.

d. Water Quantities

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Groundwater from the upper and lower Floridan Aquifer, or if available and practicable, a local source of reclaim (reuse) water are potential water sources.

Potential Site # 4: Fort Myers Plant Site, Lee County

FPL's existing 460-acre Fort Myers property is located just east of Interstate 75 in Lee County and is adjacent to the Caloosahatchee River. The existing facilities on the site include one 1,440 MW (approximate) combined cycle unit, 12 gas turbines, each with an approximate capacity of 54 MW, and 2 combustion turbines, each with an approximate capacity of 160 MW.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Fort Myers plant site is found at the end of this chapter.

b. Land Uses

The land on the site is currently dedicated to industrial use with surrounding grassy and landscaped areas. Much of the site has been used in recent years for direct plant construction activities. The adjacent land uses include light commercial and retail to the east of the property, plus some residential areas located toward the west.

c. **Environmental Features**

Mixed scrub with some hardwoods can be found to the east and further south.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

The available water source is the Caloosahatchee River and the available groundwater source is the sandstone aquifer.

Potential Site # 5: Lauderdale Plant, Broward County

The Lauderdale site is located in Eastern Broward County approximately 5 miles inland from Dania Beach and less than 2 miles west of Ft. Lauderdale International Airport. The site is bounded on the south by Dania Cutoff Canal, the east by S.W. 30th Avenue, and the North by I-595.

The existing approximately 1,700 MW of generating capacity at FPL's Lauderdale site occupies a portion of the approximately 210 acres that are wholly owned by FPL. The generating capacity is made up of two combined cycle units (Units 4 & 5), and 24 simple cycle gas turbine (GT) units.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. **Land Uses**

The existing power plant facilities are located on approximately 130 acres. The existing site has been in use since the 1920s and is adjacent to a county resource recovery project.

c. **Environmental Features**

To the north of the power plant is an area of mixed uplands with a scattering of small wetlands.

d. Water Quantities

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Existing groundwater or the municipal water supply are potential water sources.

Potential Site # 6: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District (SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad.

The existing approximately 3,700 MW of generating capacity at FPL's Martin site occupies a portion of the approximately 11,300 acres that are wholly owned by FPL. The generating capacity is made up of two steam units (Units 1 & 2), plus three combined cycle units (Units 3, 4, & 8). In addition, a 10 kilowatt (kw) photovoltaic (PV) facility also in operation at the south end of the site. The site includes a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

a. U.S. Geological Survey (USGS) Map

A USGS map for the site is found at the end of this chapter.

b. Land Uses

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres.

c. Environmental Features

To the east of the power plant there is an area of mixed pine flat wood with a scattering of small wetlands. To the north of the cooling pond there is a 1,200-acre area which has been set aside as a mitigation area. There is a peninsula of wetland forest on the West Side of the reservoir that is named the Barley Barber Swamp. The Barley Barber Swap encompasses 400 acres and is preserved as a natural area. There is also a 10-kilowatt (kW) photovoltaic energy facility at the south end of this site.

d. Water Quantities

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Surface water resources currently used at the Martin facility include the cooling pond which takes its water from the St. Lucie canal. The available ground water resource is the surficial aquifer system which is used as a source of potable and service water.

Potential Site # 7: Port Everglades Plant, Broward County

The 94-acre FPL Port Everglades plant site is located at Port Everglades in Broward County. The site has convenient access to State Road (S.R.) 84 and I-595. Rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (approximate) and two 400 MW (approximate) sized units. The four steam boilers are capable of firing residual fuel oil, natural gas, or a combination of both. The site also is home to 12 simple cycle gas turbine (GT) peaking units of 30 MW (approximate) each. The GT units are part of the Gas Turbine Power Park that is made up of 24 GTs at the Lauderdale Plant site and the 12 GTs at the Port Everglades site. The GTs are capable of firing either natural gas or liquid fuel.

a. U.S. Geological Survey (USGS) Map

A map of the site is found at the end of this chapter.

b. Land Uses

The land on this site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

c. **Environmental Features**

The shoreline of the intake and discharge canal banks are vegetated with fringing mangrove, with some open, maintained grass areas on the side.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Existing groundwater or the municipal water supply could be used for industrial process and makeup water. Industrial cooling water needs could be met using the existing once-through cooling water system.

Potential Site # 8: Riviera Plant, Palm Beach County

The FPL Riviera Plant property is located in Riviera Beach in Palm Beach County. The site has direct access to a four-lane highway, U.S. 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (approximate) steam boiler generating units and one retired 50 MW generating unit.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. **Land Uses**

The land on the site is primarily covered by the existing generation facilities. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development. The plant property contains some open, maintained grass area.

c. **Environmental Features**

The site is located on the Intra-coastal waterway near the Lake Worth Inlet which provides warm water refugia for manatees during cold winter days.

d. **Water Quantities**

As previously discussed, if additional water is needed beyond the currently permitted amount, then water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

The existing municipal water supply could be used for industrial processing water. Industrial cooling water needs could be met using the existing once-through cooling water system from Lake Worth.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance which is available to the FPL system and the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new units that may not adversely impact such limitations. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations and by evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system. Both site- and system-related transmission costs are developed for each different unit/unit location option or groups of options. In addition, transfer limits for capacity and energy that can be imported into the Southeastern region of FPL's system are also developed for use in FPL's production costing analyses. (A further discussion of the Southeastern Florida region and transmission imports is found in Section III.C.)

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's planned transmission facilities to interconnect and integrate FPL's resource plans and those that must be certified under the Transmission Line Siting Act are presented in Section III.E.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.[3]

In its resource planning work in 2007, FPL utilized the load forecast that was presented in FPL's Determination of Need filings to the FPSC for advanced technology coal units, capacity uprates to FPL's existing nuclear units, and for two new nuclear units. In its resource planning work in early 2008, FPL utilized an updated load forecast. Both forecasts were considered the base forecast at those times and no sensitivity tests to either of those load forecasts were developed or utilized.

[3] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its fuel price forecasts are discussed in Chapter III of this document. FPL's 2007 and early 2008 resource planning work utilized up to four different fuel cost forecasts (and four different environmental compliance cost forecasts). Detailed discussions of those fuel cost forecasts, and the results of utilizing them on the resource plans being analyzed in each filing, were presented to the FPSC in FPL's filings for Determination of Need for advanced technology coal units, capacity uprates to FPL's existing nuclear units, and for two new nuclear units.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item #3, FPL used up to four fuel forecasts in the filings for Determination of Need for advanced technology coal units, capacity uprates to FPL's existing nuclear units, and for two new nuclear units. While these forecasts did not represent a constant cost differential between oil/gas and coal, a variety of fuel cost differentials were represented in these forecasts.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 and Schedule 8 present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add, for planning purposes, over the planning horizon is presented on the Schedule 9 forms.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

In its 2007 and early 2008 resource planning work, FPL used a variety of key financial assumptions as forecasts changed. A 44.2% debt and 55.8% equity FPL capital structure was used throughout. In analysis for the advanced coal technology units, FPL used a 7.2% projected debt, an equity return of 12.3%, and after-tax discount rate of 8.93% for generation costs and 8.82% for all other costs. In analysis for the combined cycle units, FPL used a 6.43% projected debt, an equity return of 11.75%, and after-tax discount rate of 8.4% for generation costs and 8.3% for all other costs. FPL did not test the sensitivity of a specific resource plan to varying financial assumptions.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). As discussed in response to Discussion Item #2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective are identical when DSM levels are unchanged between competing plans. Therefore, in planning work in which DSM levels were unchanged, the equivalent cumulative present value of revenue requirements perspective was utilized.

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two system reliability criteria in its resource planning work. One of these is a minimum 20% Summer and Winter reserve margin. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the reliability standards established by the North American Electric Reliability Corporation (NERC) in its *Reliability Standards*. FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Reliability Standards* are available on the internet (http://www.nerc.com/.)

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Transmission Facility Rating Methodology* document that are also available on FPL's Open Access Same Time Information System (OASIS) at https://www.oatioasis.com/FPL/index.html.

The normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95/0.95	1.05/1.07
230	0.95/0.95	1.06/1.07
500	0.95/0.95	1.07/1.09

There may be isolated cases for which FPL may determine it prudent to deviate from the general criteria stated above. The overall potential impact on customers and the probability of an outage actually occurring, as well as other factors, would influence the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption is revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

The Executive Summary provides a discussion of two system concerns that are typically addressed in FPL's resource planning work: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida. In addition, the Executive Summary also presented a discussion of a new factor introduced in 2007 that impacts FPL's resource planning work, the Executive

Order issued by Florida's Governor Crist in July 2007 that, in part, called for a significant reduction in greenhouse gas emissions in Florida and for an increase in the amount of energy provided by renewable, non-emitting sources.

In addition to these system concerns/issues, there are other strategic factors FPL typically considers when choosing between resource options. These include the following: (1) technology risk; (2) environmental risk, and (3) site feasibility. The consideration of these factors may include both economic and non-economic aspects.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts on the FPL system, including environmental compliance costs. Technologies regarded as more acceptable from an environmental perspective for a plan are those which minimize environmental impacts for the FPL system as a whole through highly efficient fuel use and state of the art controls.

Site feasibility assesses a wide range of economic, regulatory, and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed, elements of FPL's capacity additions include the construction of new generating capacity at the West County Energy Center (WCEC) site, WCEC Units 1 & 2. This generation construction projects was selected after evaluating competing bids received in response to Requests for Proposals (RFP) issued by FPL. The FPSC subsequently approved FPL's decision to construct these new combined cycle units in

Determination of Need dockets. FPL has followed a virtually identical RFP process in reaching its WCEC 3 decision.

The construction capacity addition decisions projected in this document for 2014 and beyond are expected to be conducted in a manner consistent with the Commission's Bid Rule.

Identification of self-build options beyond those units already approved by the FPSC and Governor and Siting Board, or units for which FPL is currently seeking approval, in FPL's Site Plan is not an indication that FPL has pre-judged any capacity solicitation it may conduct. The identification of future capacity units is required of FPL and represents those alternatives that appear to be FPL's best, most cost-effective self-build options at this time. FPL reserves the right to refine its planning analyses and to identify other self-build options. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an RFP is issued for supply-side resources, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

(1) FPL identified the need for a new 230kV transmission line (by December 2008) that required certification under the Transmission Line Siting Act which was issued on April 21, 2006. The new line, when completed, will connect FPL's St. Johns Substation to FPL's proposed Pringle Substation (also shown on Table III.E.1). The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

(2) FPL has identified the need for a new 230kV transmission line (by December 2011) that requires certification under the Transmission Line Siting Act. The new line will connect FPL's Manatee Substation to FPL's proposed BobWhite Substation (also shown on Table III.E.1). The construction of this line is necessary to serve existing and future customers in the Manatee and Sarasota areas in a reliable and effective manner.

RE: 2009-2018 Ten-Year Power Plan Site Plan 090000-OT

Dear Ms. Cole:

In accordance with Rule 25-22.071, F.A.C., please find enclosed for filing the original and twenty-five (25) copies of Florida Power & Light Company's 2009-2018 Ten-Year Power Plant Site Plan.

Please acknowledge your receipt of the above filing on the enclosed copy of this letter and return to the undersigned. Thank you for your assistance on this matter.

Sincerely,

Monica L. Padron

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (F.A.C.).

This Ten Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2008 and that were on-going in the first Quarter of 2009. The forecasted information presented in this plan addresses the 2009–2018 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten-year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings, at the appropriate time.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, based on FPL's IRP work in 2008 and

early 2009.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as Preferred and Potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional information that is to be included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2009 Ten Year Power Plant Site Plan (Site Plan) presents FPL's current plans to augment and enhance its electric generation capability (owned or purchased) as part of its efforts to meet its projected incremental resource needs for the 2009 - 2018 time period. By design, the primary focus of this document is on supply side additions; i.e., electric generation capability. The supply side additions discussed in this document are resources projected to be needed after accounting for FPL's extensive demand side management (DSM) contributions and the significant energy efficiency contributions from the latest, enhanced federal appliance and lighting efficiency standards. The projected impacts of the federal appliance and lighting efficiency standards are included in FPL's load forecast presented in this document. The projected impacts of FPL's DSM contributions are addressed as reductions to the forecasted load.

The resource plan that is presented in FPL's 2009 Site Plan contains two key similarities to the resource plan presented in FPL's 2008 Site Plan, especially for the early years of the ten-year period. However, there are also three significant changes in the current resource plan compared to the resource plan presented in the 2008 Site Plan. These similarities to, and changes from, the 2008 Site Plan, plus the factors driving these changes are discussed below.

I. Similarities to the Resource Plan Presented in the 2008 Site Plan:

There are two key similarities in the current resource plan presented in this document compared to the resource plan presented in the 2008 Site Plan.

Similarity # 1: Three highly efficient combined cycle (CC) generating units and increases in generating capacity at FPL's existing nuclear units will be added to FPL's system in 2009 - 2012.

One similarity is the addition of new highly efficient natural gas-fired CC generating units and increased generating capacity from FPL's existing nuclear units in the 2009 through 2012 time period. FPL will be adding three 1,219 MW (Summer) CC units in western Palm Beach County during 2009 through 2011. The site for these units is named the West County Energy Center (WCEC) and these units are identified as WCEC Units 1, 2, and 3. The WCEC Unit 1 and WCEC Unit 2 were approved by the Florida Public Service Commission (FPSC) in June 2006. Site certification for these units under the Florida Electric Power Plant Siting Act was approved by the Governor and the Cabinet serving as the Siting Board in December 2006. The WCEC Unit 3 was approved by the FPSC in September 2008 and FPL's site certification for this unit was approved in November 2008.

In addition, FPL will be adding approximately 400 MW of increased generating capacity at its existing nuclear power plants at its Turkey Point and St. Lucie sites. This increased capacity is scheduled to come in-service in 2011 and 2012. The need for these capacity "uprates" was approved by the FPSC in January 2008. The Final Order for the Site Certification was issued in September 2008 for the St. Lucie uprates and October 2008 for the Turkey Point uprates.

Similarity # 2: The amount of projected DSM additions remains unchanged in this Site Plan. These projections are subject to change in late 2009 based on the outcome of the 2009 DSM Goals proceeding before the FPSC.

The other key similarity to the resource plan presented in the 2008 Site Plan is the amount of additional DSM that is projected to be implemented annually over the ten-year period. There is essentially no change in the amount of projected annual DSM additions between the 2008 Site Plan and the 2009 Site Plan.

The DSM values presented in the 2009 Site Plan are based on meeting FPL's currently approved DSM Goals through 2014, plus implementing additional cost-effective DSM through 2014 that was identified by FPL after the current DSM Goals were established, and a projection of continued DSM additions in 2015 through 2017 at an annual implementation rate commensurate with that in the years leading up to 2014. Because the 2009 Site Plan addresses one more year (2018) than did the 2008 Site Plan, FPL has extended its DSM projection out one more year to 2018 using a similar annual implementation rate.

However, FPL is scheduled to present its new projections of cost-effective DSM to the FPSC in June 2009. These new projections will be used to determine FPL's new DSM Goals for the years 2010 through 2019. The analyses to develop these new projections of cost-effective DSM for the new DSM Goals are currently a work in progress at the time the 2009 Site Plan is being filed. The final order from the FPSC establishing FPL's new DSM Goals is expected in the 4th Quarter of 2009. The subsequent development and approval of FPL's DSM Plan (with which FPL will meet the new Goals) will likely be made in early 2010. Therefore, the impact of FPL's new DSM Goals and DSM Plan will be reflected next year in FPL's 2010 Site Plan.

II. Factors That Are Driving Changes in FPL's Resource Plan:

There are two primary "change factors" that are largely driving the changes in FPL's 2009 resource plan compared to the resource plan presented in FPL's 2008 Site Plan. These two change factors, and their impacts on the resource plan, are summarized below and are addressed in more detail in Chapters II and III of this document.

Change Factor # 1: The load forecast is significantly lower than in previous years.

The first factor that is driving changes in the current resource plan is FPL's new long-term load forecast that was prepared in January 2009. With this new forecast, FPL now projects lower growth in electrical demand over the ten-year period addressed in this document. The projection of lower load growth is primarily driven by several factors including: a forecasted lower rate of population growth, an economic downturn lasting several years, and increased energy efficiency impact from the latest enhanced federal appliance and lighting efficiency standards. The combined effect of these three drivers results in projected lower growth in electrical demand for the entire ten-year period (2009 – 2018) addressed in this document, compared to the projected load growth discussed in FPL's 2008 Site Plan.

Change Factor # 2: Highly Efficient New Generation Capacity has been approved by the FPSC and is now reflected in FPL's Resource Plan in 2010-2018.

The second change factor is the inclusion of highly efficient new generating capacity that was approved by the FPSC during 2008. This new generating capacity was shown to be cost-effective, to enhance system fuel diversity, and to reduce FPL's system emission rates. This new generating capacity consists of new generating units that are nuclear, solar, or highly efficient new natural gas-fired CC units.

These new generating unit additions include the following:

- Two new nuclear units (Turkey Point Units 6 & 7) are projected to be brought into service in 2018 and 2020, respectively. Each unit is projected to add approximately 1,100 MW of firm capacity. The FPSC approved the need for these new nuclear units in April 2008. As part of this approval, FPL will be providing an annual feasibility analysis as part of the annual nuclear cost recovery process. A multi-year licensing and permitting review process for these units is currently underway. Because this Site Plan addresses the time period through 2018, the first of these two units, Turkey Point Unit 6, is now included in the 2009 Site Plan.

- Two new photovoltaic (PV) solar facilities are projected to be brought into service by 2010. One of these PV facilities will be placed in DeSoto County and will be named the DeSoto Next Generation Solar Energy Center. This facility is projected to have a nameplate rating of 25 MW. The second PV facility will be placed in Brevard County and will be named the Space Coast Next Generation Solar Energy Center. This PV facility is projected to have a nameplate rating of 10 MW. The FPSC approved the eligibility of expenditures for these PV facilities to be recovered through the environmental cost recovery clause in August 2008. The DeSoto Next Generation Solar Energy Center obtained an Environmental Resource Permit and an Army Corps of Engineers permit in October 2008. The Space Coast Next Generation Solar Energy Center received the Army Corps of Engineers permit in December 2008 and the Environmental Resource Permit is expected to be received in mid-2009.
- A new solar thermal facility at FPL's existing Martin plant site is also projected to be brought into service in 2010. This solar thermal facility, named the Martin Next Generation Solar Energy Center, is projected to be able to produce up to 75 MW of steam capability, thus allowing reduced use of fossil fuels by FPL when the solar thermal facility is producing steam. The FPSC approved the eligibility of expenditures for this solar thermal facility to be recovered through the environmental cost recovery clause in August 2008. FPL also received the site certification modification approval in August 2008.
- Two existing generating plants, each consisting of two older fossil fired steam generating units, are projected to be converted into new, highly efficient CC units. The existing two-unit plant at FPL's Cape Canaveral site will be replaced by a new CC unit with a projected output of 1,219 MW (Summer) in 2013. This new unit will be called the Cape Canaveral Next Generation Clean Energy Center. The existing two-unit plant at FPL's Riviera site will also be replaced by a new CC unit with a projected output of 1,207 MW (Summer) in 2014. This new unit will be called the Riviera Beach Next Generation Clean Energy Center. These conversions were approved by the FPSC in September 2008. The site certification application for Cape Canaveral was filed in December 2008 and the site certification application for Riviera Beach was filed in February 2009. A decision is expected to be reached regarding these applications by early 2010.

These new generating units were selected and incorporated into FPL's resource plan for a variety of reasons including cost-effectiveness, significant system fuel savings, and significant system emission reductions, including greenhouse gas emission reductions. In addition, the solar projects will increase the contribution of renewable energy sources towards meeting the electricity needs of FPL's customers.

III. Resulting Changes in FPL's Resource Plan Compared to the 2008 Site Plan:

The impact of the two change factors discussed above, plus other concerns discussed later in this chapter and in Chapter III, have resulted in three significant changes in FPL's resource plan presented in this document compared to the resource plan presented in FPL's 2008 Site Plan. These resulting changes are summarized below.

Resulting Change # 1: FPL's resource plan now reflects greater contributions from nuclear energy and renewable energy.

The first of FPL's two planned 1,100 MW nuclear units that is scheduled to come in-service in 2018 (the second unit is scheduled to come in-service in 2020 but is not addressed in this document due to the later in-service date), plus the addition of 35 MW of PV and 75 MW of solar thermal in 2010, are new to FPL's resource plan this year. These new units will increase the contribution from both nuclear and renewable energy. In turn, this reduces fossil fuel use by FPL's system from what it otherwise would have been.

This decrease in fossil fuel usage will also contribute to lowering FPL system emission rates, including greenhouse gas emission rates, thus lowering system emissions from what they would otherwise have been if these generating units were not added. In regards to carbon dioxide (CO_2), FPL already has a relatively low CO_2 emission rate (CO_2 tons per MWh generated) compared to other utilities. The planned additions of new nuclear capacity, highly efficient CC capacity including the conversions of two existing plants, and the PV and solar thermal contributions will result in a further lowering of FPL's system CO_2 emission rate, thus working to offset the upward pressure on emissions that will be caused by continuing population and electrical load growth in FPL's service territory.

Resulting Change # 2: Other than the new generating units that have recently been approved, FPL projects that it will add no additional new generating units to meet capacity needs through 2018.

FPL's lower load forecast in January 2009 results in a significantly lower resource need projection for the next ten years than was the case with the 2008 Site Plan. The lower resource need can be effectively met by the new generating units that have recently been approved. As shown by the table ES.1 below, FPL projects no additional FPL generation unit additions through 2018 beyond the above-mentioned units that were approved in 2008. (However, this resource plan is subject to change for a variety of reasons including the need to address potential new laws and/or regulations related to renewable energy.)

Resulting Change # 3: FPL will also place on Inactive Reserve some of its existing generating units starting in 2009.

The lower resource need projection discussed above has also led FPL to reflect in its resource plan the temporary removal of a number of its existing, older, less efficient generating units from active service starting in 2009. These units will continue to be maintained and will be returned to active service as needed.

FPL's existing Cape Canaveral and Riviera plants will be placed in Inactive Reserve as early as the Summer of 2009. The Cape Canaveral plant is scheduled to be permanently removed in 2010, and the Riviera plant will be permanently removed in 2011, as part of the conversion projects. In addition, the following older, less efficient units will also be placed on Inactive Reserve status in 2009 and 2010: Cutler Units 5 & 6, Port Everglades Units 1 & 2, Sanford Unit 3, Martin Unit 2, and Manatee Unit 2[1]. FPL will continue to maintain these units and will again utilize these units (other than those at Riviera and Cape Canaveral where new units will be constructed) as resource needs dictate. For purposes of this planning document, FPL projects that these units will begin to be returned to operation starting in 2016. A further discussion of these units is presented in Chapter III.

Table ES.1 presents a current projection of the changes in the generating resources portion of FPL's resource plan based on the factors and changes discussed above. As such, this table does not directly address FPL's significant DSM contributions, but FPL's significant projected DSM contributions were fully accounted for by FPL and the FPSC in the process of approving the need for the new generating units presented in the table.

FPL's ongoing resource planning efforts will continue to be influenced by the two change factors discussed above (i.e., a new lower load forecast and the addition of highly efficient nuclear, solar, and CC generation already approved by the FPSC). In addition, other items will also influence FPL's resource planning work. Among these items are two that FPL refers to as on-going system concerns that FPL has considered in its resource planning work for a number of years. These on-going system concerns include: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida.

In addition, two other relatively recent developments will also influence FPL's continuing resource planning efforts. One of these is the Executive Orders directive issued in 2007 by Governor Crist calling for reduction in greenhouse gas emissions and greater contribution from renewable

[1] The two 800 MW units, Martin Unit 2 and Manatee Unit 2, on this list may be replaced at some time in the future by two similar size units, Martin Unit 1 and Manatee Unit 1. If this were to occur, Martin Unit 1 and Manatee Unit 1 would be temporarily placed on Inactive Reserve status and Martin Unit 2 and Manatee Unit 2 would be returned to active service.

energy sources. As previously discussed, FPL's resource planning has already taken positive steps in regard to both of these issues.

The other development is the ongoing effort to establish a Florida standard for renewable energy contributions to a utility system. A Renewable Portfolio Standard (RPS) proposal prepared by the FPSC has been sent to the Florida Legislature for consideration during the legislative session that began in March 2009. Because the eventual RPS outcome is not known at the time the 2009 Site Plan is being prepared, the resource plan presented in FPL's 2009 Site Plan does not directly address any RPS decision. Assuming that an RPS decision is reached later in 2009, FPL will then determine what steps need to be taken to address the standard. These steps will be discussed next year in FPL's 2010 Site Plan.

Table ES.1: Projected Capacity Changes and Reserve Margins for FPL

Year	Projected Capacity Changes	Net Capacity Changes (MW) Winter (2)	Summer (3)	Reserve Margin (%) Winter	Summer

	TOTALS =	4,226	3,119		

Table heading: Projected Capacity Changes and Reserve Margins for FPL (1)

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of the year shown.
(3) Summer values are values for August of the year shown.
(4) These are firm capacity and energy contracts with QF, utilities, and other entities. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown except for WCEC 1 and WCEC 2 that are projected to be in-service in August 2009 and December 2009, respectively. WCEC 1 is included in the Summer reserve margin calculation starting in 2009 and in the Winter reserve margin calculation starting in 2010. WCEC 2 is included in both the Summer and Winter starting in 2010. All additions assumed to start in June are included in the Summer reserve margin calculation starting in that year and in the Winter reserve margin calculation starting with the next year.
(6) Because of the intermittent nature of the photovoltaics (PV) resource, FPL is currently assigning no firm capacity benefit to these generating additions. FPL will reassess this once actual operating data from the PV facilities at these locations is available. This location-specific information is needed in order to gauge consistent output during the peak hours which are accounted for in FPL's reserve margin calculations.
(7) The Martin solar thermal facility is designed to provide steam for FPL's existing Martin Unit 8 combined cycle unit, thus reducing FPL's use of natural gas. No additional capacity (MW) will result from the operation of the solar thermal facility.
(8) A number of existing FPL power plants are being temporarily removed from service and placed on Inactive Reserve status. FPL plans to return these units to active service in the future as needed. The timing of the return of these units to full-time active status is uncertain at this time primarily due to the uncertainty regarding FPL's future load. However, for planning purposes, FPL is showing in this document that these units begin to return to active service starting in 2016.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.7 million people. FPL served an average of 4,509,729 customer accounts in thirty-five counties during 2008. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management (DSM), and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, Florida. The current generating facilities consist of four nuclear units, three coal units, twelve combined cycle (CC) units, seventeen fossil steam units, forty-eight combustion gas turbines, one simple cycle combustion turbine, and five diesel units. The location of these ninety generating units is shown on Figure I.A.1 and in Table I.A.1. The second page of Table I.A.1 provides a "break down" of the capacity provided by the combustion turbine (CT) and steam turbine (ST) components of FPL's existing CC units.

FPL's bulk transmission system is comprised of 6,727 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 580 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

FPL Generating Resources by Location

Location/ Map Key	Plant Name	Number of Units	Summer MW
A	Turkey Point	5	3,322
B	St. Lucie *	2	1,553
C	Manatee	3	2,735

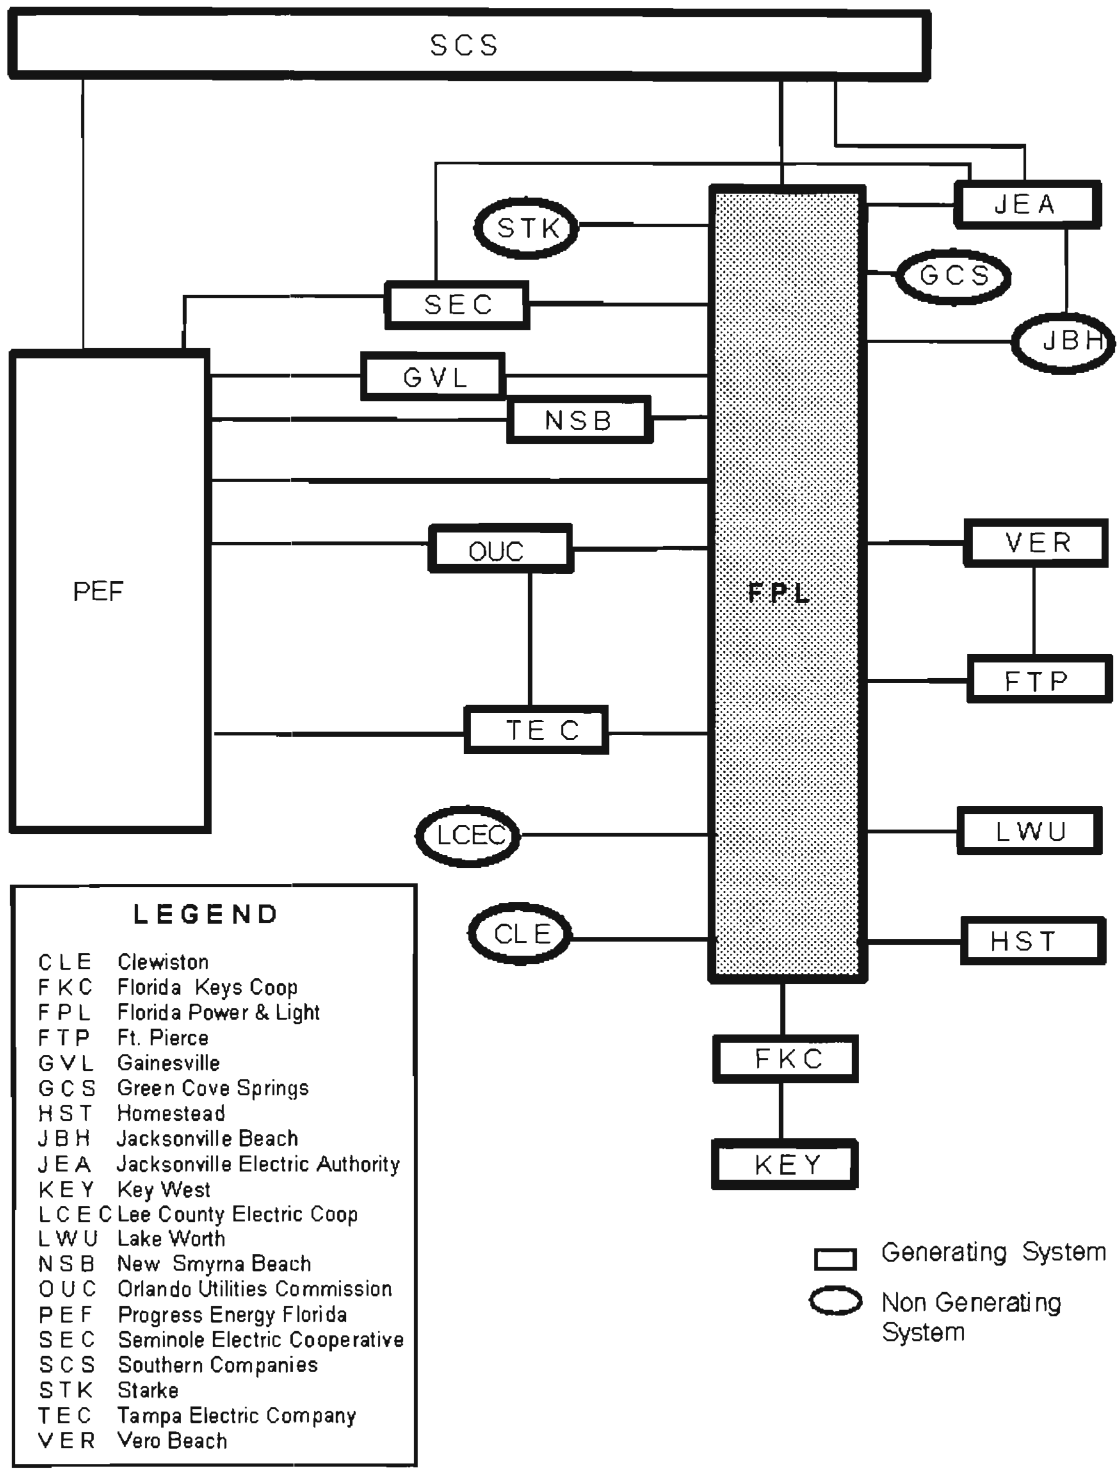

Figure I.A.3: FPL Interconnection Diagram

I.B Firm Capacity Power Purchases

Purchases from Qualifying Facilities (QF):

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five qualifying facilities; i.e., cogeneration/small power production facilities, to purchase firm capacity and energy as shown in Table I.A.2, Table I.B.1, and I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Purchases from Utilities:

FPL has a Unit Power Sales (UPS) contract to purchase 931 MW, with a minimum of 380 MW, of coal-fired generation from the Southern Company (Southern) through May 2010. An additional contract with Southern will result in FPL receiving 930 MW from June 2010 through the end of December 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 381 MW (Summer) and 390 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. However, due to Internal Revenue Service (IRS) regulations, the total amount of energy that FPL may receive from this purchase is limited. FPL currently assumes, for planning purposes, that this limit will be reached in the first half of 2016. Once this limit is reached, FPL will be unable to receive firm capacity and energy from these purchases.

These purchases are shown in Table I.A.2, Table I.B.1, and Table I.B.2. FPL also has ownership interest in the SJRPP units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.

Other Purchases:

FPL has other firm capacity purchase contracts with a variety of Non-QF suppliers. These purchases are generally near-term in nature. Table I.B.1 and I.B.2 present the Summer and Winter MW, respectively, resulting from all firm purchased power contracts discussed above through the year 2018. For planning purposes, FPL assumes an additional 105 MW of firm capacity will be supplied from renewable energy sources. This firm capacity is expected to be provided from two sources including: 55 MW through contract extension with an existing renewable facility currently under contract with FPL but whose contract is set to expire in 2010, and 50 MW through one or more proposals received in response to a Renewable RFP, such as the RFP that FPL issued in April 2008.

I.D. Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include a number of conservation/energy efficiency and load management initiatives. FPL's DSM efforts through 2008 have resulted in a cumulative Summer peak reduction of approximately 4,109 MW at the generator and an estimated cumulative energy saving of approximately 46,646 Gigawatt Hour (GWh) at the generator. After accounting for reserve margin requirements, FPL's DSM efforts through 2008 have eliminated the need to construct the equivalent of approximately 12 new 400 MW generating units.

For purposes of the projections presented in this document, FPL is utilizing essentially the same projection of DSM that was utilized in FPL's 2008 Site Plan. This amount of DSM is based on: FPL's current DSM Goals that were approved by the Florida Public Service Commission through 2014, additional cost-effective DSM identified by FPL after these DSM Goals were established, and a projection of continued DSM implementation for 2015 – 2018 at an implementation rate commensurate with the projected annual rate of implementation for the years immediately preceding 2014.

FPL will be submitting proposed new DSM Goals for 2010 – 2019 to the FPSC in a June 2009 filing and the analysis work that will lead to FPL's proposed new DSM Goals is in its early stages as this document is prepared. A final order from the FPSC regarding the proposed DSM amounts is expected in the 4th Quarter of 2009. FPL will formally incorporate the approved new DSM Goals amounts into its resource planning work at that time. The new DSM Goals amounts, the approved DSM Plan with which FPL will achieve those Goals, and the resource planning work that incorporates this DSM will be presented in FPL's 2010 Site Plan.

										Total System as of December 31, 2008 =		**23,358**	**22,087**

1/ These ratings are peak capability.
2/ These ratings represent Florida Power & Light Company's share of Scherer Unit No. 4, adjusted for transmission losses.
3/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Unit No. 1 and No. 2, excluding Jacksonville Electric Authority (JEA) share of 80%.
4/ Total capability of each unit is 853/839 MW. FPL's ownership share of St. Lucie 1 and 2 is 100%(853/839) and 85% (714/726) respectively as shown above. FPL's share of the deliverable capacity from each unit is approx. 92.5% and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

II. A. Overview of the Load Forecasting Process

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are typically developed on an annual basis for resource planning work at FPL. New long-term forecasts were developed by FPL in January 2009 that replaced the previous long-term load forecasts that were used by FPL during 2008 in much of its resource planning work and which were presented in FPL's 2008 Site Plan. These new load forecasts are utilized throughout FPL's 2009 Site Plan. These forecasts are a key input to the models used to develop FPL's integrated resource plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

Consistent with past forecasts, the primary drivers to develop these forecasts include economic conditions and weather.

The projections for the national and Florida economies are obtained from the consulting firm Global Insight. Population projections are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects FPL's energy sales and peak demand. Two sets of weather variables are developed and used in FPL's forecasting models:

1. Cooling and Heating Degree-Hours are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Hours are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. A composite temperature hourly profile is derived using hourly temperatures across FPL's service territory. Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained. In developing the composite hourly profile, these regional temperatures are weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Hours which are based on starting point temperatures of 72°F and 66°F degrees, respectively. Similarly, composite temperature and hourly profile of temperatures are used for the Summer and Winter peak models.

II. B. Comparison of FPL's Current and Previous Load Forecasts

FPL's current load forecast is significantly different from the load forecast presented in its 2008 Site Plan. The current load forecast projects lower load growth. There are three factors that are the primary drivers behind the lower load forecast: projected lower population growth, higher energy efficiency impacts from new enhanced federal standards for appliance and lighting efficiency, and the effects of a lingering recession.

The customer forecast is based on a review of recent population projections from the University of Florida and Global Insight, as well as an analysis of historical population trends. Population projections through 2011 are derived from the University of Florida's October 2008 population projections which are significantly lower than prior projections. According to the University of Florida, net migration has fallen to a record low as a result of the economic slowdown and is expected to remain at historically low levels until 2010. Consequently, FPL's projects that customer growth in 2009 and 2010 will be significantly below the historical average. As population growth recovers, a modest rebound in customer growth is projected in 2011. Population growth after 2011 is based on the average levels experienced historically. As a result of lower growth in the initial years of the forecast, the total number of customers in the current load forecast remains below the levels projected in FPL's 2008 Site Plan in all years.

The impact of higher energy efficiency resulting from new federal standards for appliances and lighting is based on estimates developed by ITRON, an energy industry consulting firm. ITRON developed estimates for the impact of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the naturally occurring energy reductions resulting from the adoption of compact florescent light bulbs. As a result of these appliance and lighting standards, FPL now projects that by 2018, FPL's Summer peak demand will be approximately 2,095 MW lower than it otherwise would have been. This projected impact from higher appliance and lighting standards is 839 MW more than the 1,256 MW reduction assumed in the 2008 Site Plan. In the 2008 Site Plan, only the impact of the 2005 National Energy Policy Act was considered.

Economic conditions in the state are also projected to have a significant impact on the forecast. Economic conditions in the state have deteriorated significantly since the 2008 Site Plan was published. After leading the nation in job creation, Florida is now leading the nation in job losses. Likewise, Florida now ranks second in the nation in terms of foreclosures and personal bankruptcies. The severity of current economic conditions suggests that Florida will likely experience a longer recession than that projected by Global Insight. Based on the examination of past recessions and review of forecasts from a number of outside experts, FPL developed an economic outlook reflecting a lingering recession through 2010 and below average growth in 2011. A resumption of cyclical growth, as forecasted by Global Insight, is forecasted by 2012.

Although the projected load growth for FPL is below that presented in FPL's 2008 Site Plan, the total growth projected by FPL for the ten-year reporting period of this document is still substantial. The Summer peak is projected to increase to 26,143 MW by 2018, an increase of 5,066 MW over the 2008 actual summer peak. Likewise, NEL is projected to reach 132,136 GWH in 2018, an increase of 21,092 GWH from the actual 2008 value. This compares to projected increases of 6,659 MW and 41,352 GWH over the ten-year reporting period presented in FPL's 2008 Site Plan compared to the 2007 actual values.

II.C. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class for the forecasting period of 2009-2027 and are adjusted to match the NEL forecast. The results of these sales forecasts for the years 2009-2018 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and NEL forecast are outlined below.

1. <u>Residential Sales</u>

Residential electric usage per customer is estimated by using an econometric model. Residential sales are a function of: Cooling Degree-Hours and Heating Degree-Hours, real price of electricity (a 12-month moving average), Florida real household disposable income, dummy variables for the month of January and the specific month of November 2005, and an intercept term. A dummy variable for the calendar month of January was included to improve the predictability of the model by accounting for the otherwise higher than predicted usage in that model. A dummy variable for November 2005 was included because an analysis of residuals identified that data point as an outlier. The price of electricity plays a role in explaining electric usage, because electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. To capture economic conditions, the model includes Florida's real household disposable income. The degree of economic prosperity can, and does, affect residential electricity sales. The impact of weather is captured by the Cooling Degree-Hours and Heating Degree-Hours. Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted.

2. **Commercial Sales**

The commercial sales forecast is also developed using an econometric model. Commercial sales are a function of the following variables: Florida non-agricultural employment, commercial real price of electricity (a 12-month moving average), Cooling Degree-Hours, as well as an autoregressive term. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree-Hours are used to capture weather-sensitive load in the commercial sector. The model also includes an intercept and two binary variables to account for statistical outliers in November 2005 and January 2007.

3. **Industrial Sales**

Industrial sales were forecasted using an econometric model. The model utilizes the following variables: Florida Housing Starts, Cooling Degree-Hours, industrial real price of electricity (a 24-month moving average), and several dummy variables for outliers. The Cooling Degree-Hour is used to capture the weather-sensitive load in the industrial class.

4. **Railroad & Railways Sales and Street and Highway Sales**

The forecast for street and highway sales is developed using historical usage patterns and multiplying these usage levels by the number of forecasted customers. The projections for railroad & railways sales are based on historical average use per customer because the number of customers is projected to remain the same. This class consists solely of the Miami-Dade County's Metrorail system.

5. **Other Public Authority Sales**

This revenue class is a closed class with no new customers being added. This class consists of sports fields and a government account. The forecast for this class is based on historical knowledge of its usage characteristics.

6. **Total Sales to Ultimate Customer**

Sales forecasts by revenue class are summed to produce a total sales forecast.

7. Sales for Resale

Sales for resale (wholesale) customers are composed of municipalities and/or electric co-operatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers. Currently there are four customers in this class: the Florida Keys Electric Cooperative; City of Key West; Metro-Dade County; and Seminole Electric Cooperative. In addition, FPL will begin serving the Lee County load in 2010.

FPL provides service to the Florida Keys under a long-term partial requirements contract. The sales for Florida Keys are forecasted using a regression model.

FPL's sales to the City of Key West are expected to terminate in 2013. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor.

Metro-Dade County sells 60 MW to Florida Progress. Line losses are billed to Metro-Dade under a wholesale contract.

Seminole Electric Cooperative has contracted for delivery of 75 MW for the period of December 2008 through December 2009. Also included in the forecast is a 200 MW sale to Seminole Electric beginning in June 2014 to December 2040.

Lee County has contracted for FPL to supply a portion of their load beginning in January 2010 and for FPL to supply their total load beginning in January 2014 through December 2033. Forecasted sales to Lee County are based on assumptions regarding their contract demand and expected load factor.

II.D. Net Energy for Load (NEL)

An econometric model is developed to produce an NEL forecast. The key inputs to the model are: the real price of electricity (a 12-month moving average), Cooling and Heating Degree-Hours, and Florida real household disposable income. In addition, the model also includes an autoregressive term as well as a dummy variable for the calendar month of February. A dummy variable for the calendar month of February was added to account for the lower than otherwise predicted usage associated with that month.

The forecast is further adjusted for the impacts of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and compact florescent light bulbs. The forecast was also adjusted for additional load estimated from hybrid cars beginning in 2012 which resulted in an increase of approximately 244 GWH by the end of the ten-year reporting period. An adjustment was also made to the forecast to account for the increase in the number of empty homes which has resulted from the current housing slump. Because the increase in empty homes is viewed as a cyclical phenomenon, only the initial years of the forecast were impacted by this adjustment.

Once the NEL forecast is obtained using the above-mentioned model, total billed sales are computed using a historical ratio of sales to NEL. The sales by class forecasts previously discussed are then adjusted to match the NEL from the annual NEL model. The forecasted NEL values for 2009 – 2018 are presented in Schedule 3.3 that appears at the end of this chapter.

II.E. System Peak Forecasts

The rate of absolute growth in FPL system peak load has been a function of a growing customer base, varying weather conditions, projected economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient appliances and lighting. FPL developed the peak forecast models to capture these behavioral relationships. Similar to the NEL forecast, the peak forecasts are also adjusted for the empty homes in the first three years of the forecast horizon as well as for the impacts of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the impact of compact fluorescent light bulbs. The forecast was also adjusted for additional load estimated from hybrid cars which resulted in an increase of approximately 49 MW by the end of the ten-year reporting period.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2009–2018 are presented in Schedules 3.1 and 3.2 as well as in Schedules 7.1 and 7.2.

1. <u>System Summer Peak</u>

The Summer peak forecast is developed using an econometric model. The variables included in the model are the price of electricity, Florida real household disposable income, Cooling Degree-Hours in the day prior to the peak, and the average temperature on the day of the peak. The model below is based on the Summer peak contribution per customer and is, therefore, multiplied by total customers to derive FPL's system Summer peak.

2. System Winter Peak

Like the system Summer peak model, this model is also an econometric model. The model consists of two weather-related variables: the average temperature on the peak day and Heating Degree-Hours for the prior day as well as for the morning of the Winter peak day. In addition, Florida real household disposable income is a variable used in the model. The model below is based on the Winter peak contribution per customer and is, therefore, multiplied by total customers to derive FPL's system Winter peak.

3. Monthly Peak Forecasts

The forecasting process for monthly peaks is basically the same as for the monthly NEL forecast and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peaks.

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.F. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2009-2027 are produced using a System Load Forecasting "shaper" program. This model uses years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

II.G. Uncertainty

In order to address uncertainty in the forecasts of aggregate peak demand and NEL, FPL first evaluates the assumptions underlying the forecasts. FPL takes a series of steps in evaluating the input variables, including comparing projections from different sources, identifying outliers in the series, and assessing the series' consistency with past forecasts. In addition, FPL reviews factors which may affect the input variables. This may require reviewing data from local economic development boards or from FPL's own Customer Service Business Unit. Other factors which may be considered include demographic trends and housing characteristics such as starts, size, and vintage of homes.

Uncertainty is also addressed in the modeling process. Generally, econometric models are used to forecast the aggregate peak demand and NEL. During the modeling process, the relevant statistics (goodness of fit, F-statistic, P-values, mean absolute deviation (MAD), mean absolute percentage error (MAPE), etc.) are scrutinized to ensure that the models adequately explain historical variation. Once a forecast is developed, it is compared with past forecasts. Deviations from past forecasts are examined in light of changes in input assumption to ensure that the drivers underlying the forecast are well understood. Finally, forecasts of aggregate peak demand and NEL are compared with their actual values as they become available. An ongoing process of variance analyses is performed. To the extent that the variance analysis identifies large unexplained deviations between the forecast and actual values, revisions to the econometric model may be considered.

The inherent uncertainty in load forecasting is addressed in different ways in regard to FPL's overall resource planning and operational planning work. In regard to FPL's resource planning work, FPL's utilization of a 20% reserve margin criterion (approved by the FPSC) is designed, in part, to maintain reliable electric service for FPL's customers in light of forecasting uncertainty. In regard to operational planning, a extreme weather load forecast for the projected Summer peak day is produced. The maximum average temperature on the day of the Summer peak over the last twenty years is used to produce this extreme weather forecast. Likewise, the minimum average temperature on the day of the Winter peak is used to estimate the extreme weather Winter peak forecast. The extreme weather scenarios are typically estimated for a two-to- five year period.

II.H. DSM

The effects of FPL's DSM implementation to-date are assumed to be imbedded in the actual usage data for forecasting purposes. Any change in usage pattern, be it the impact of FPL's DSM efforts, price impact, or weather impact, is reflected in the actual observed load data. Therefore, energy efficiency impacts, whether market-driven or as a result of FPL's DSM programs, are assumed to be included in the historical usage data for peaks and NEL.

The load forecasts provided in the schedules at the end of this chapter are not adjusted for incremental energy efficiency that FPL plans to implement in future years. The impacts of this incremental energy efficiency, plus the impacts of FPL's cumulative and incremental load management programs, are accounted for as "line item reductions" to the forecasts as part of the IRP process as shown in Schedules 7.1 and 7.2. After making these adjustments to the load forecasts, the resulting "firm" load forecast is then used in FPL's IRP work.

Schedule 2.1
History and Forecast of Energy Consumption And Number of Customers by Customer Class

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
			Rural & Residential			Commercial		
Year	Population 1/	Members per Household	GWH 2/	Average 3/ No. of Customers	Average KWH Consumption Per Customer	GWH 2/	Average 3/ No. of Customers	Average KWH Consumption Per Customer

Historical Values (1999 - 2008):

1/ Population represents only the area served by FPL.

2/ Actual energy sales include the impacts of existing conservation. These values are at the meter.

3/ Average No. of Customers is the annual average of the twelve month values.

Projected Values (2009 - 2018):

1/ Population represents only the area served by FPL.

2/ Forecasted energy sales do not include the impact of incremental conservation. These values are at the meter.

3/ Average No. of Customers is the annual average of the twelve month values.

2008	993	7,092	111,004	3,347	4,509,729
2009	1,149	7,213	109,440	3,405	4,519,986
2010	2,137	7,042	110,207	3,435	4,548,763
2011	2,252	7,161	111,926	3,470	4,607,594
2012	2,280	7,358	114,815	3,519	4,707,005
2013	2,172	7,394	116,027	3,580	4,806,155
2014	5,122	7,631	121,128	3,649	4,904,959
2015	5,844	7,768	123,800	3,722	5,003,480
2016	5,952	7,925	126,278	3,796	5,101,804
2017	6,070	8,087	128,908	3,871	5,199,999
2018	6,202	8,289	132,136	3,946	5,298,111

Historical Values (1999 - 2008):

3/ Average No.of Customers is the annual average of the twelve month values.

5/ GWH Col. (19) = Col. (16) + Col. (17) + Col. (18). Actual NEL include the impacts of existing conservation and agrees to Col. (8) on Schedule 3.3.

6/ Actual energy sales include the impacts of existing conservation. These values are at the generator.

7/ Total Col. (21) = Col. (5) + Col. (8) + Col. (11) + Col. (20).

Projected Values (2009 - 2018):

2/ Forecasted energy sales do not include the impact of incremental conservation and agrees to Col. (2) on Schedule 3.3.

3/ Average No.of Customers is the annual average of the twelve month values.

5/ GWH Col. (19) = Col. (16) + Col. (17) + Col. (18). Matches to Col (2) on Schedule 3.3 for Forecasted \

6/ Total Col. (21) = Col. (5) + Col. (8) + Col. (11) + Col. (20).

2014	23,533	1,184	22,349	0	1,120	329	804	121	240	20,919
2015	24,142	1,205	22,937	0	1,146	385	812	128	278	21,393
2018	24,772	1,229	23,543	0	1,172	440	820	136	316	21,888
2017	25,401	1,256	24,145	0	1,198	496	828	143	353	22,383
2018	26,143	1,284	24,860	0	1,207	514	831	145	366	23,080

Historical Values (1999 - 2008):

Col. (2) - Col. (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 10), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (10) for 1999 through 2008 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial /Industrial Demand Reduction (CDR).

Col (9) represents FPL's Business On Call program.

Col. (11) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (11) is derived by the formula:Col. (11) = Col.(2) - Col.(6) - Col.(8)- Col. (9).

Projected Values (2009 - 2018):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col. (10) represent all incremental conservation,current load management and incremental load management. These values are projected August values and the conservation values are based on projections with a 1/2008 starting point designed for use with the 2008 load forecast.

Col (9) represents FPL's Business On Call program.

Col. (11) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (11) is derived by using the formula: Col. (11) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9)-Col (10).

Schedule 3.2
History and Forecast of Winter Peak Demand:Base Case

2008	18,055	163	17,892	0	879	644	635	0	279	16,541
2009	20,031	216	19,815	0	922	48	729	0	31	18,380
2010	18,790	329	18,461	0	938	73	767	0	41	18,971
2011	19,120	334	18,786	0	955	105	775	0	53	17,232
2012	19,710	340	19,370	0	973	138	763	0	67	17,749
2013	20,098	346	19,752	0	992	171	791	0	81	18,063
2014	21,154	878	20,278	0	1,012	205	799	0	97	19,041
2015	21,882	1,100	20,783	0	1,036	239	807	0	113	19,687
2016	22,396	1,123	21,273	0	1,060	273	815	0	130	20,118
2017	22,912	1,148	21,764	0	1,084	307	823	0	146	20,552
2018	23,466	1,173	22,293	0	1,106	338	631	0	181	21,030

Historical Values (1999 - 2008):

Col. (2) - Col. (4) are actual values for historical winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 10), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col.(10) for 2000 through 2008 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial/Industrial Demand Reduction (CDR).

Col (9) represents FPL's Business On Call program.

Col. (11) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (11) is derived by the formula: Col. (11) = Col. (2) - Col. (6) - Col. (8).

Projected Values (2009 - 2018):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col.(10) represent all incremental conservation and cumulative load control. These values are projected January values and the conservation values are based on projections with a 1/2008 starting point designed for use with the 2008 load forecast.

Col (9) represents FPL's Business On Call program.

Col. (11) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (11) is derived by using the formula: Col. (11) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9)- Col.(10).

Schedule 3.3
History of Annual Net Energy for Load - GWH: Base Case
(All values are "at the generator"value except for Col (8))

(1)	(2) = (3) + (3) + (5)	(3)	(4)	(5)	(6)	(7)	(8) = (5) - (6) - (7)	(9)
Year	Total Net Energy For Load without DSM	Residential Conservation	C/I Conservation	**Actual** Net Energy For Load	Sales for Resale GWH	Utility Use & Losses	**Actual** Total Billed Retail Energy Sales (GWH)	Load Factor(%)
1999	94,365	1,542	1,365	91,458	953	5,829	84,676	59.3%
2000	99,097	1,674	1,434	95,989	970	7,059	87,960	61.4%
2001	101,739	1,789	1,545	98,404	970	7,222	90,212	59.9%
2002	107,755	1,917	1,639	104,199	1,233	7,443	95,523	61.9%
2003	112,160	2,008	1,759	108,393	1,511	7,386	99,496	62.9%
2004	112,031	2,106	1,834	108,091	1,531	7,464	99,095	59.9%
2005	115,440	2,205	1,934	111,301	1,506	7,498	102,298	56.6%
2006	117,490	2,312	2,041	113,137	1,569	7,909	103,659	59.2%
2007	118,894	2,373	2,206	114,315	1,499	7,401	105,415	59.4%
2008	115,755	2,485	2,267	111,004	993	7,092	102,919	60.0%

Historical Values (1999 - 2008):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: Col. (2) = Col. (3) + Col. (4) + Col. (5).

Col.(3) & Col.(4) for 1999 through 2008 are DSM values starting in January 1988 and are annual (12-month) values.Col. (3) and Col. (4) for 2008 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWH reductions actually experienced each year .

Col. (5) is the actual Net Energy for Load (NEL) for years 1999 - 2008.

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (5) - Col. (6) - Col. (7).

Col. (9) is calculated using Col. (5) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (5)*1000) / ((Col.(2) * 8760)
Adjustments are made for leap years.

Forecast of Annual Net Energy for Load - GWH: Base Case
(All values are "at the generator"value except for Col (8))

(1)	(2)	(3)	(4)	(5) = (2) - (3) - (4)	(6)	(7)	(8) = (2) - (6) - (7)	(9)
Year	**Forecasted** Net Energy For Load without DSM	Residential Conservation	C/I Conservation	Net Energy For Load Adjusted for DSM	Sales for Resale GWH	Utility Use & Losses	**Forecasted** Total Billed Retail Energy Sales (GWH) without DSM	Load Factor(%)
2009	109,440	142	106	109,192	1,149	7,213	101,078	59.1%
2010	110,207	236	155	109,816	2,137	7,042	101,029	59.5%
2011	111,926	334	207	111,386	2,252	7,161	102,514	59.6%

NOV	16,538	7,886	16,788	8,265	16,835	8,384
DEC	14,849	7,502	15,786	7,936	15,791	8,070
TOTALS		111,004		109,440		110,207

* Forecasted Peaks & NEL do not include the impacts of cumulative load management and incremental conservation and are consistent with values shown in Col. (19) of Schedule 2.3 and Col (2) of Schedule 3.3.

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990s and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2008 and early 2009 resource planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental steps to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Evaluate the competing options and resource plans in regard to system economics and non-economic factors; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

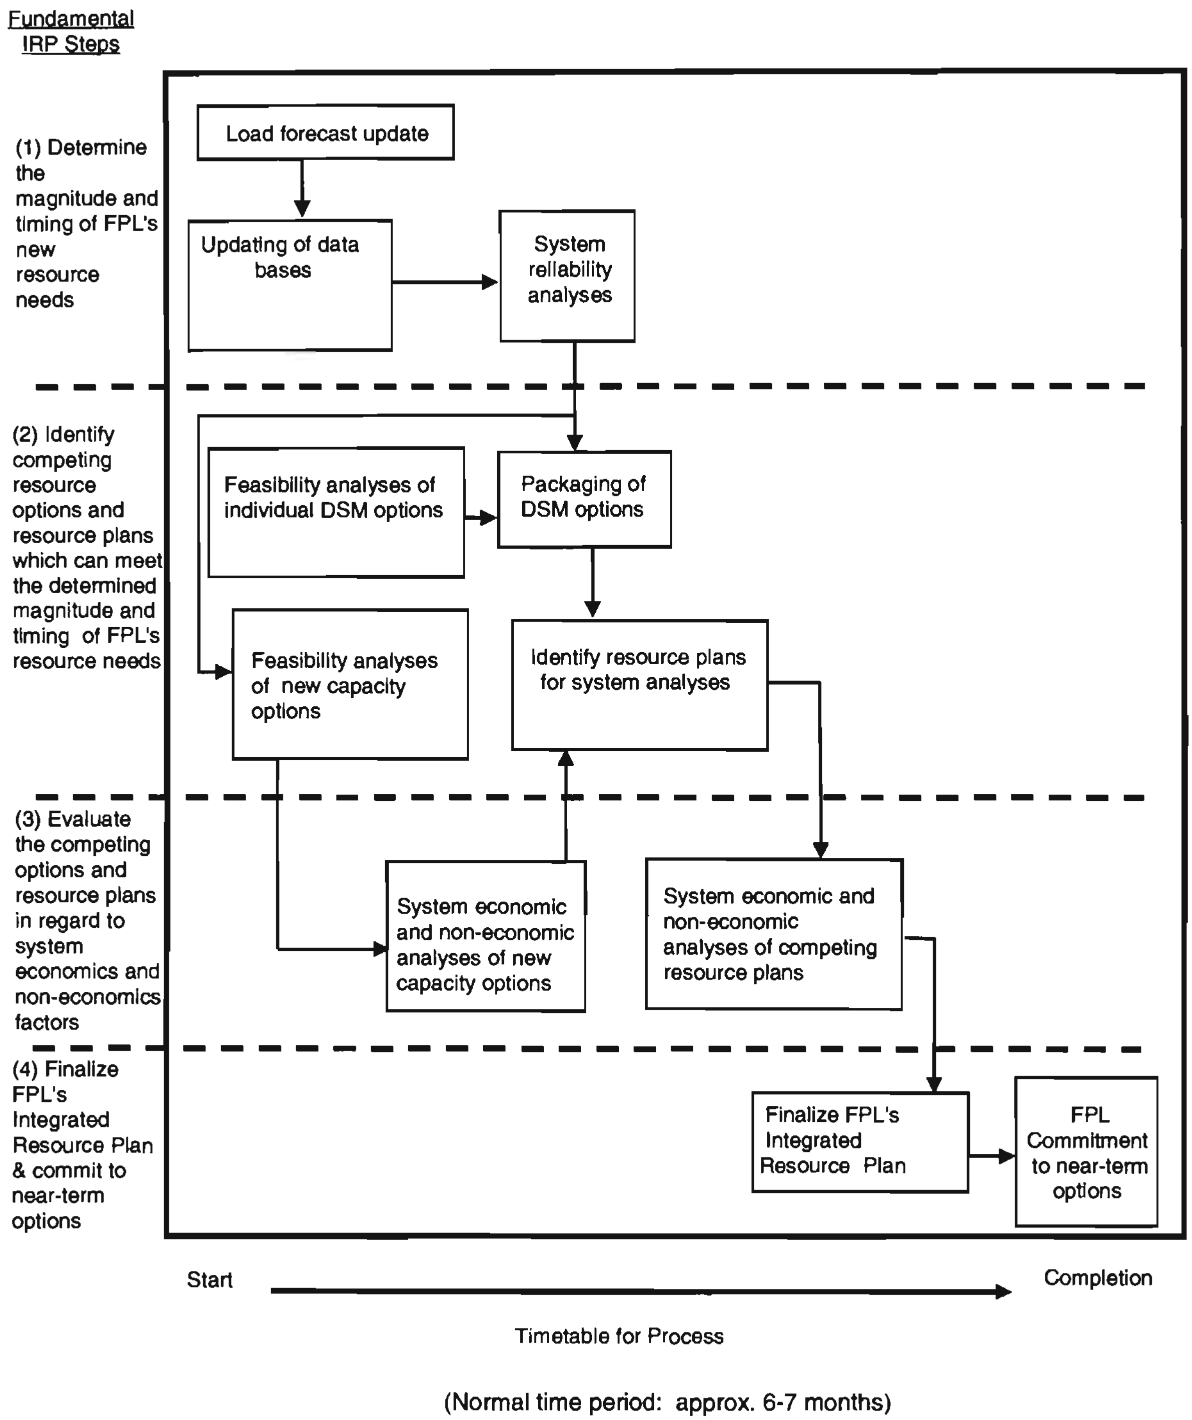

Figure III.A.1: Overview of FPL's IRP Process

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of the four resource planning steps, determining the magnitude and timing of FPL's resource needs, is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed to maintain system reliability. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a reliability assessment, or resource adequacy, analysis for the utility system.

Step 1 typically starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information that is used in many of the fundamental steps in resource planning. Examples of this new information include, but not limited to: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) firm capacity power purchases, and (3) DSM implementation.

The first of these assumptions is based on new generating capacity additions that have been approved by the Florida Public Service Commission (FPSC) through Determination of Need hearings that evaluated both the need for, and the cost-effectiveness of, each of the new capacity additions. These generating capacity additions have also either received the necessary Site Certification approvals from either the Secretary of the Florida Department of Environmental Protection (FDEP) or the Governor and Cabinet (acting as the Siting Board) or, as in the case of the new nuclear units, are in the process of receiving the necessary state and federal approvals. A number of new generating unit additions will occur in the 2009 – 2018 time frame that is addressed in this document.

These generating unit additions include:

- Three new natural gas-fired CC units at FPL's West County Energy Center (WCEC) site that are scheduled to come in-service during 2009 through 2011. These new units will each add approximately 1,219 MW (Summer) of generation capacity. FPL selected these CC units, designated as WCEC Units 1, 2, & 3, after conducting two Request for Proposals (RFP) solicitations and evaluating the options received in response to the RFPs.

- Two new photovoltaic (PV) solar energy facilities are projected to be brought into service by 2010. One of these PV facilities will be placed in DeSoto County and will be named the DeSoto Next Generation Solar Energy Center. This facility is projected to have a nameplate rating of 25 MW. The second PV facility will be named the Space Coast Next Generation Solar Energy Center and is projected to have a nameplate rating of 10 MW. The FPSC approved the eligibility of expenditures for these PV facilities to be recovered through the environmental cost recovery clause in August 2008. The DeSoto Next Generation Solar Energy Center obtained an Environmental Resource Permit and an Army Corps of Engineers permit in October 2008. The Space Coast Next Generation Solar Energy Center received the Army Corps of Engineers permit in December 2008 and expects to receive the Environmental Resource Permit in mid-2009.
- A new solar thermal facility at FPL's existing Martin plant site is also projected to be brought into service in 2010. This solar thermal facility, named the Martin Next Generation Solar Energy Center, is projected to be able to produce up to 75 MW of steam capability, thus allowing reduced use of fossil fuels by FPL when the solar thermal facility is producing steam. The FPSC approved the eligibility of expenditures for this solar thermal facility to be recovered through the environmental cost recovery clause in August 2008. FPL received the site certification modification approval in August 2008.
- Two existing generating plants, each consisting of two older fossil fuel-fired generating units, are projected to be converted into new, highly efficient CC units. The existing plant at FPL's Cape Canaveral site will be replaced in 2013 by a new CC unit with a projected output of 1,219 MW. This new plant will be called the Cape Canaveral Next Generation Clean Energy Center. The existing plant at FPL's Riviera site will be replaced in 2014 by a new CC unit with a projected output of 1,207 MW. This new plant will be called the Riviera Beach Next Generation Clean Energy Center. These conversions were approved by the FPSC in September 2008. The site certification application for Cape Canaveral was filed in December 2008 and the site certification application for Riviera Beach was filed in February 2009. A decision is expected to be reached regarding these applications in early 2010.
- Two new nuclear units (Turkey Point Units 6 & 7) are projected to be brought into service in 2018 and 2020, respectively. Each unit is projected to produce approximately 1,100 MW. The FPSC approved the need for these new nuclear units in April 2008. As part of this approval, FPL will be providing a annual feasibility analysis as part of the annual nuclear cost recovery process. A multi-year permitting review process for these units is currently underway. Because this Site Plan

addresses the time period through 2018, the first of these two units, Turkey Point Unit 6, is now included in the 2009 Site Plan.

- In addition, FPL will be adding approximately 400 MW of increased generating capacity at its existing nuclear power plants at its Turkey Point and St. Lucie sites. This increased capacity is scheduled to come in-service in 2011 and 2012. These capacity "uprates" were approved by the FPSC in January 2008. The Final Order for the Site Certification was issued in September 2008 for the St. Lucie uprates and October 2008 for the Turkey Point uprates.

These new generating units were added for a variety of reasons including cost-effectiveness, significant system fuel savings, and significant system emission reductions, including greenhouse gas emission reductions. In addition, the solar projects will increase the contribution of renewable energy sources towards meeting the electricity needs of FPL's customers.

The second of these assumptions involves firm capacity power purchases. FPL's current projection of firm capacity purchases is very similar to the projection shown in FPL's 2008 Site Plan. These firm capacity purchases are from a combination of utility and independent power producers. Details, including the annual total capacity values for these purchases, are presented in Chapter I in Tables I.B.1 and I.B.2. These purchased capacity amounts were incorporated in FPL's resource planning work.

The third of these assumptions involves a projection of the amount of additional demand side management (DSM) that is projected to be implemented annually over the ten-year period. Since 1994, FPL's resource planning work has assumed that at least the DSM MW called for in FPL's approved DSM Goals will be achieved as planned. This is again the case with the resource plan FPL discusses in its 2009 Site Plan.

There is essentially no change in the amount of DSM shown between the 2008 Site Plan and the 2009 Site Plan. The DSM values that are presented in this 2009 Site Plan, are based on meeting FPL's currently approved DSM Goals through 2014, plus implementing additional cost-effective DSM through 2014 that was identified by FPL after the current DSM Goals were established, and a projection of continued DSM additions in 2015 through 2017 at an annual implementation rate commensurate with that in the years leading up to 2014. Because the 2009 Site Plan addresses one more year (2018) than did the 2008 Site Plan, FPL has extended its DSM projection out one more year to 2018 using a similar annual implementation rate.

However, FPL is scheduled to present its new projections of cost-effective DSM to the FPSC in June 2009. These new projections will be used to determine FPL's new DSM Goals for the years 2010 through 2019. The analyses to develop these new projections of cost-effective DSM for the new DSM Goals are currently a work in progress at the time the 2009 Site Plan is being filed. The final order from the FPSC establishing FPL's new DSM Goals is expected in the 4th Quarter of 2009. The subsequent development and approval of FPL's DSM Plan (with which FPL will meet the new Goals) will likely be made in early 2010. Therefore, the impact of FPL's new DSM Goals and DSM Plan will be reflected next year in FPL's 2010 Site Plan.

These key assumptions, plus the other updated information, are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the reliability of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss-of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of

LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program used by FPL.

The result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. Information regarding the timing and magnitude of these resource needs is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analyses of new capacity options are conducted to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs. In similar analyses, feasibility analyses of new DSM options and/or continued growth in existing DSM options are conducted.

The individual new resource options emerging from these feasibility options are then typically "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using spreadsheet, dynamic programming, and/or linear and non-linear programming techniques.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs are identified.

Step 3: Evaluate the Competing Options and Resource Plans in Regard to System Economics and Non-Economic Factors:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for evaluating these resource options and resource plans. In 2008, once the resource plans were developed, FPL utilized the P-MArea production cost model and a Fixed Cost Spreadsheet to perform the economic analyses. The P-MArea model is the model used by FPL to develop the Fuel Cost Budget and to conduct other production cost-related analyses.

FPL also utilized several other models in the economic evaluation portion of its resource planning work. For analyses of individual DSM options, FPL typically uses its DSM cost-effectiveness model which is an FPL spreadsheet model utilizing the FPSC's approved methodology for analyzing the cost-effectiveness of individual DSM measures/programs, and its non-linear programming model for analyzing the potential for lowering system peak loads through additional load management capacity.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases in which the DSM contribution was assumed as a given and the only competing options were new generating units and/or purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans in such cases were evaluated on a cumulative present value revenue requirement (CPVRR) basis.

Other factors are also included in FPL's evaluation of resource options and resource plans. While these factors may have an economic component or impact, they are often discussed in quantitative, but non-economic terms, such as percentages, etc. rather than in terms of dollars. These factors are often referred to by FPL as "system concerns" that include (but are not necessarily limited to) maintaining/enhancing fuel diversity in the FPL system and maintaining a regional balance between load and generating capacity, particularly in Southeastern Florida. In conducting the evaluations needed to determine which resource options and resource plans are best for FPL's system, both the economic and non-economic evaluations are conducted with an eye to whether the system concern is positively or negatively impacted by a given resource option or resource plan.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps were used to develop the future generation plan. This plan is presented in the following section.

III.B Incremental Resource Additions/Changes

FPL's projected incremental generation capacity additions/changes for 2009 through 2018 are depicted in Table III.B.1. These capacity additions/changes result from a variety of actions including: changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls), temporarily removing older, less efficient generating units from active service and placing them into Inactive Reserve status, changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, increases in generating capacity at FPL's four existing nuclear units, the conversion of FPL's existing steam generating units at its existing Cape Canaveral and Riviera sites into new, very fuel-efficient CC generating units, and by construction of approved new generating units.

As shown in Table III.B.1, the capacity additions are largely made up of construction of new CC and nuclear generating units, the conversion of existing steam units into new CC units, and capacity increases at FPL's existing nuclear generating units. (The DSM MW that FPL is adding each year are not presented in this table but have been accounted for by FPL and the FPSC in the process of obtaining approval for these new capacity additions.)

This table also shows the addition of the previously discussed 110 MW of new solar facilities (35 MW of PV and 75 MW of solar thermal). However, as indicated in the table and its footnotes, these new solar facilities are not projected to contribute new firm capacity. There are two reasons for this. First, one of these facilities – the 75 MW solar thermal facility at the Martin site – is designed not to add new capacity, but to serve as a "fuel substitute" facility. When sufficient sunlight is available, the solar thermal facility will produce steam that would otherwise have been produced by burning fossil fuels. Second, in regard to the two new PV facilities that together have a 35 MW nameplate rating, it is unclear at this time what the output of these PV facilities will consistently be during FPL's late afternoon Summer and early morning Winter peak hours. Consequently, FPL is not assigning a firm capacity value (i.e., those values reflected in Table III.B.1) to these PV facilities at this time. Once FPL has actual operating experience with these PV facilities in these specific locations, it will evaluate what an appropriate firm capacity value for each of the facilities should be. However, FPL's economic and non-economic analyses fully capture the system fuel and emission savings from these three new solar facilities.

FPL is also currently assuming, for planning purposes, that it is likely to obtain additional capacity and/or energy from Renewable RFP solicitations, other proposed purchases, or its own renewable energy development efforts. For purposes of this planning document, FPL is assuming that 50 MW of firm capacity purchases from new renewable facilities will be added to FPL's system in the ten-year reporting period. In addition, one of FPL's existing renewable purchase power contracts is set to expire in 2010. For purposes of this planning document, FPL is assuming that a new contract for 55 MW of firm capacity and energy will be entered into. This is discussed further in Section III.F.

The significantly lower new load forecast, coupled with the approved additions of highly efficient new nuclear, solar, and natural gas-fired generating capacity, allow the opportunity for FPL to temporarily remove some older, less efficient generating capacity from active service, resulting in savings in operational and maintenance costs. A number of such units will be placed on Inactive Reserve status starting in 2009. The existing units that will be placed on Inactive Reserve include: Cutler Units 5 & 6, Sanford Unit 3, Port Everglades Units 1 & 2, Martin Unit 2, and Manatee Unit 2. These units will continue to be maintained and will be returned to active service when needed. The timing of the return of these units is uncertain at this time primarily due to the uncertainty regarding FPL's future load. However, for planning purposes, FPL is showing in this document that these units begin to return to active service starting in 2016.

In addition, the existing units at the Cape Canaveral and Riviera sites that will be converted to CC generation as part of the Conversions, will first be placed on Inactive Reserve status, then will be completely removed from service in preparation for the construction of the new units at those sites.

In regard to FPL's projected reserve margin values, these values are higher than the values projected in the 2008 Site Plan. As a consequence, no new uncommitted generation is projected to be needed in the 2009 – 2018 time frame, subject to changes in laws and regulations regarding renewable energy.[2]

[2] For purposes of establishing a Standard Offer Contract, and using the same forecasts and other assumptions presented in this document, FPL projects that it's next fossil-fueled new generating unit would be a Greenfield 3x1 G CC with a 2021 in-service date. Details of that unit are not provided in this Site Plan because its projected in-service date is beyond the 2009-2018 time period addressed in this document.

Table III.B.1: Projected Capacity Changes for FPL

Projected Capacity Changes and Reserve Margins for FPL (1)			
		Net Capacity Changes (MW)	
Year	Projected Capacity Changes	Winter (2)	Summer (3)
2009	Changes to Existing Purchases (4)	---	(479)

2018	Turkey Point Nuclear Unit 6 (5)	---	1,100
	Inactive Reserve of Existing Units - online (8)	834	---
	TOTALS =	4,226	3,119

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are values for January of the year shown.
(3) Summer values are values for August of the year shown.
(4) These are firm capacity and energy contracts with QF, utilities, and other entities. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown except for WCEC 1 and WCEC 2 that are projected to be in-service in August 2009 and December 2009, respectively. WCEC 1 is included in the Summer reserve margin calculation starting in 2009 and in the Winter reserve margin calculation starting in 2010. WCEC 2 is included in both the Summer and Winter starting in 2010. All additions assumed to start in June are included in the Summer reserve margin calculation starting in that year and in the Winter reserve margin calculation starting with the next year.
(6) Because of the intermittent nature of the photovoltaics (PV) resource, FPL is currently assigning no firm capacity benefit to these generating additions. FPL will reassess this once actual operating data from the PV facilities at these locations is available. This location-specific information is needed in order to gauge consistent output during the peak hours which are accounted for in FPL's reserve margin calculations.
(7) The Martin solar thermal facility is designed to provide steam for FPL's existing Martin Unit 8 combined cycle unit, thus reducing FPL's use of natural gas. No additional capacity (MW) will result from the operation of the solar thermal facility.
(8) A number of existing FPL power plants are being temporarily removed from service and placed on Inactive Reserve status. FPL plans to return these units to active service in the future as needed. The timing of the return of these units to full-time active status is uncertain at this time primarily due to the uncertainty regarding FPL's future load. However, for planning purposes, FPL is showing in this document that these units begin to return to active service starting in 2016.

III.C Issues Impacting FPL's Resource Planning Work

FPL's ongoing resource planning efforts will continue to be influenced by the two driving factors previously discussed: a new lower load forecast and the addition of a significant amount of new highly efficient nuclear, solar, and CC generating capacity that has been approved by the FPSC. In addition, there are at least four other issues that will impact FPL's resource planning work. FPL refers to two of these issues as on-going system concerns that FPL has considered in its resource planning work for a number of years. These on-going system concerns include: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida.

In addition, two other relatively recent issues have emerged that will also influence FPL's resource planning efforts. These include: (3) the Executive Orders directive issued in 2007 by Governor Crist calling for reduction in greenhouse gas emissions and greater contribution from renewable energy sources, and (4) a Florida standard for renewable energy contributions to a utility system.

These four (4) issues that impact FPL's on-going resource planning work are briefly discussed below.

1. **<u>System Fuel Diversity</u>**

FPL is currently dependent upon using natural gas to generate approximately half of the electricity it delivers to its customers. Therefore, FPL is continually seeking to maintain and enhance the fuel diversity of its system.

In 2007, FPL sought approval from the FPSC to add two new advanced technology coal units to its system. These two new units would have been placed in-service in 2013 and 2014. However, due to concerns over greenhouse gas emissions, FPL was unable to obtain approval for these units. Consequently, FPL does not believe that new advanced technology coal units are viable fuel diversity enhancement options in Florida for the foreseeable future.

Therefore, FPL has turned its attention to nuclear energy, renewable energy, and more efficient ways in which to generate electricity using natural gas in order to enhance its fuel diversity. In regard to nuclear energy, FPL obtained approval to increase capacity at each of FPL's four existing nuclear units by up to 104 MW. In total, these capacity "uprates" will add a total of approximately 400 MW to the FPL system in the 2011/2012 time period. In 2008, the FPSC approved the need for these uprates and the ability to recover expenditures related to these uprates. In 2008, FPL also obtained FPSC approval for the need to add two new nuclear units at FPL's existing Turkey Point site and the ability to recover expenditures related to these new units. These two new nuclear units are projected to add approximately 2,200 MW to FPL's system. The first of these units is projected to come in-service in 2018 and the second unit to come in-service in 2020 (i.e., outside of the ten-year reporting period of this document).

FPL also has been involved in activities to investigate adding or maintaining renewable resources as a part of its generation supply. One of these activities is a variety of discussions with existing facilities aimed at maintaining or extending current agreements that are scheduled to end during the ten-year reporting period of this document. Another activity is to attempt to solicit cost-effective new renewable projects from outside parties. With respect to the latter, FPL issued a second Request for Proposals (RFP) for new renewable energy capacity and energy in April 2008 and FPL is analyzing those responses. Also, as previously discussed, FPL sought and received approval from the FPSC to add 110 MW of new FPL-owned solar facilities, both solar thermal and PV, in 2008. These FPL facilities are all scheduled to be in-service by 2010. FPL's efforts to utilize renewable energy are discussed further in Section III.F.

In regard to using natural gas more efficiently, FPL received approvals in 2008 from the FPSC to build a third highly efficient CC unit at its West County Energy Center site (WCEC Unit 3) and to convert the older steam generating units at its existing Cape Canaveral and Riviera plant sites to new, highly efficient CC units. These new CC units will go in service in 2011, 2013, and 2014, respectively.

In the future, FPL will continue to identify and evaluate alternatives that may maintain or enhance system fuel diversity. FPL also plans to maintain the ability to utilize fuel oil at those existing units that have that capability, although cost factors currently limit the expected use of these facilities. Furthermore, FPL has traditionally purchased the gas transportation capacity required for new natural gas generating units from an existing natural gas pipeline company. As an alternative, FPL is developing plans with the goal of filing for a Need Determination by the FPSC for construction of a new natural gas pipeline in Florida capable of serving future generation needs. Such a pipeline would benefit FPL and its customers by increasing the diversity of FPL's fuel supply sources, the physical reliability of the pipeline delivery system, and competition among pipelines.

2. Southeastern Florida Imbalance

In recent years an imbalance had developed between regionally installed generation and peak load in Southeastern Florida. A significant amount of energy required in the Southeastern Florida region during peak periods was being provided through the transmission system from plants located outside the region. FPL's prior planning work concluded that either additional installed generating capacity in this region, or transmission capacity capable of delivering additional electricity from outside the region, would be required to address this imbalance.

Partly because of the lower transmission-related costs resulting from their location, four recent capacity additions: Turkey Point Unit 5, and WCEC Units 1, 2, & 3, were evaluated as the most cost-effective options to meet FPL's capacity needs in the near-term. Adding these units will significantly reduce the imbalance between generation and load in Southeastern Florida.

In addition, FPL will be adding increased capacity at FPL's existing two nuclear units at Turkey Point in 2011/2012 and will be increasing the generating capacity at its Riviera site through the conversion of the existing plants at that site in 2014. The result of these approved generating unit additions in Southeastern Florida are expected to address the imbalance for most, if not all, of the 2009-2018 reporting period addressed in this document even after accounting for temporarily placing some of the existing generating units in the region on Inactive Reserve status. However, the Southeastern Florida imbalance will remain a concern in FPL's on-going resource planning work.

3. Governor Crist's Executive Orders

The Executive Orders issued in 2007, particularly the portions of those Orders directing significant increases in renewable, non-emitting energy and decreases in greenhouse gas emissions, are being addressed by FPL in a variety of ways. With respect to renewable energy, FPL's efforts to procure capacity from renewable energy sources, and to build its own renewable energy facilities, were mentioned above in regard to fuel diversity and are also discussed in more detail in Section III.F.

These renewable energy efforts have the potential to help lower greenhouse gas emissions. In addition, significant reductions, particularly of carbon dioxide (CO_2), will be accomplished by the approved capacity uprates at FPL's existing nuclear units and the planned additions of two new nuclear units at FPL's existing Turkey Point site in 2018 and 2020. Further reductions in greenhouse gas emissions are also expected from increasing the overall fuel efficiency of FPL's system through the addition of the approved new generating units WCEC Units 1, 2, & 3 and the approved conversions of FPL's existing Cape Canaveral and Riviera plants. FPL will also continue to look for cost-effective ways to further improve the efficiency of its system that will lead to even more greenhouse gas emission reductions.

FPL's system CO_2 emission rate (amount of CO_2 emitted per MWh of electricity generated) is already relatively low due in large part to the overall efficiency of FPL's system. The efforts described above have the potential not only to continue the trend of steadily lowering FPL's already low CO_2 emission rate, but also to begin to lower total system CO_2 emissions despite continued growth in population.

4. **Renewable Portfolio Standards**

The ongoing effort to establish a Florida standard for renewable energy contributions to a utility system is still underway at the time this document is being prepared. A Renewable Portfolio Standard (RPS) proposal prepared by the FPSC has been sent to the Florida Legislature for consideration during the legislative session that began in March 2009. Because the eventual RPS outcome is not known at the time the 2009 Site Plan is being prepared, the resource plan presented in FPL's 2009 Site Plan does not directly address an RPS decision. Assuming that an RPS decision is reached later in 2009, FPL will determine what steps need to be taken to address the standard. These steps will be discussed next year in FPL's 2010 Site Plan.

III.D Demand Side Management (DSM)

FPL offers a wide variety of cost-effective DSM programs to its customers. In addition, FPL is actively engaged in DSM research and development. These DSM efforts are discussed in the remainder of this section.

Residential DSM Programs

1. **Residential Building Envelope:** Offers incentives to residential customers to install energy efficient reflective roof and ceiling insulation measures.

2. **Duct System Testing and Repair:** Provides reduced cost duct system testing to identify leaks in air conditioning duct systems, and encourages the repair of those leaks by qualified contractors. Incentives are offered for duct system repair.

3. **Residential Air Conditioning:** Offers incentives to customers to purchase higher efficiency heating, ventilating, and air conditioning equipment. The program includes additional incentives for: 1) plenum repair measure; 2) air handler units with electronically commutated motors; and, 3) units properly sized using FPL approved sizing software.

4. **Residential Load Management (On Call Program):** Offers load control of major appliances/household equipment to residential customers in exchange for monthly electric bill credits. Direct load control equipment is installed on selected customer end-use equipment, allowing FPL to control these customer loads as needed. Qualifying equipment (and applicable monthly credits) includes central electric air conditioners, central electric heaters, conventional electric water heaters, and swimming pool pumps.

5. **Residential New Construction (BuildSmart):** Encourages the design and construction of energy efficient homes by offering education to contractors on energy efficiency measures, and providing construction design reviews and home inspections.

6. **Residential Low Income Weatherization:** Combines energy audits and incentives to encourage low income housing administrators to retrofit homes with energy efficiency measures. The housing authorities include: weatherization agency providers (WAPS), non-weatherization agency providers (non-WAPS), and other providers approved by FPL. The incentives are used by these providers to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting. FPL offers incentives for HVAC maintenance, reduced air infiltration measures, and room air conditioning replacement.

7. **Residential Conservation Service:** Offers a walk-through energy audit, a computer-generated Class A audit, and a customer-assisted energy audit. For customer-assisted energy audits, a mail-in, phone, and Internet audit option may be offered. FPL does not apply demand and energy savings from this program towards its DSM Goals.

Business DSM Programs

1. **Business Heating, Ventilating, and Air Conditioning (HVAC):** Offers business customers financial incentives to upgrade to higher efficiency HVAC equipment that exceed the minimum efficiencies mandated by the Florida Energy Efficiency Code for Building Construction or ASHRAE Standard 90.1. The current FPL program includes

incentives for: 1) thermal storage; 2) chillers; 3) energy recovery ventilator units; 4) direct expansion (DX) units and efficient air conditioning room units; 5) demand control ventilation systems including kitchen hood control; and 6) electrically commutated motors for air conditioning systems.

2. **Business Efficient Lighting:** Offers business customers financial incentives to install high efficiency lighting measures at the time of replacement. The FPL current program offers incentives for linear fluorescent, plus other efficient, lighting technologies.

3. **Business Building Envelope:** Offers financial incentives to business customers to install high efficiency building envelope measures such as roof/ceiling insulation, reflective roof coatings, and window treatments.

4. **Business Custom Incentive:** Serves as a "catch-all" program for cost-effective business efficiency measures which are not included in other FPL programs. DSM measures must reduce or shift at least 25 kW during peak hours, have verifiable demand and energy savings, and pass FPL's cost-effectiveness testing.

5. **Business On Call:** Offers load control of central air conditioning units to both small non–demand-billed, and medium demand-billed, business customers in exchange for monthly electric bill credits.

6. **Commercial Industrial Demand Reduction (CDR):** Reduces peak demand by allowing the direct control of customer loads of 200 kW or greater. Participants contract for a firm demand level which may not be exceeded during load control periods. In return, participants receive a monthly credit. Participants must provide a 5-year termination notice to discontinue service under this rider.

7. **Business Energy Evaluation:** Offers free standard level energy evaluations on-site and on-line. More detailed evaluations are available through this audit program with costs shared between FPL and the participating customer. Participation in FPL's other business DSM programs is promoted through this program.

8. **Commercial/Industrial Load Control:** Reduces peak demand by controlling customer loads of 200 kW or greater in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

9. **Business Water Heating:** Provides financial incentives to encourage the installation of energy-efficient heat recovery units or heat pump water heaters.

10. **Business Refrigeration:** Provides financial incentives to encourage the installation of controls and equipment to reduce the usage of electric strip heat for defrosting purposes.

11. **Cogeneration and Small Power Production**: Facilitates FPL compliance with all regulatory requirements concerning qualifying facilities and small power producers. One role of the program is to assist customers in the evaluation of potential cogeneration projects, including self-generation. FPL does not project demand and energy savings from this program towards its DSM Goals.

Research And Development Programs

1. **Conservation Research and Development Program (CRD):** An umbrella research project under which new DSM technologies are analyzed. Several FPL DSM programs have emerged from the CRD program, including the business Building Envelope, Business On Call, and Residential New Construction programs. The program has also resulted in the addition of cost-effective measures to existing programs, such as the inclusion of Energy Recovery Ventilators in the Business HVAC Program. FPL operates the CRD program based on DSM Plan approval, or for 6 years, whichever occurs first, with a spending cap as approved in the most current DSM Plan.

2. **Residential Thermostat Load Control Pilot Project:** On June 15, 2007 FPL filed a petition with the FPSC for the Residential Thermostat Load Control Pilot Project. A typical barrier to customer acceptance of utility load control programs is reluctance to surrender control of heating and air conditioning appliances. Consequently, for an initial 24-month period, FPL proposed to evaluate whether the benefits of the existing On-Call Program can be expanded through use of a new generation of communication and control technologies that put residential customers in charge of decisions that could lower energy costs, while allowing customers to override FPL control of their heating and air conditioning appliances. The Commission approved FPL's request on August 14, 2007, and issued Consummating Order 07-0719 TRF-EG on September 28, 2007. The pilot project is underway and upon conclusion of the pilot, FPL will provide a final report on the results to the FPSC.

DSM Summary:

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include both conservation initiatives and load management. FPL's DSM efforts through 2008 have resulted in a cumulative Summer peak reduction of approximately 4,109 MW at the generator and an estimated cumulative energy saving of approximately 46,646 Gigawatt Hour (GWh) at the generator. Accounting for reserve margin requirements, FPL's DSM efforts through 2008 have eliminated the need to construct more than 12 new 400 MW generating units.

FPL has consistently been among the leading utilities nationally in DSM achievement. For example, according to the U.S. Department of Energy's 2006 data (the last year for which the DOE data was available at the time this Site Plan was being developed), FPL ranked # 1 nationally in energy efficiency demand reduction and # 3 nationally in load management demand reduction.

In June 2009, FPL will be submitting its proposed DSM Goals for the 2010 – 2019 time period to the FPSC for its approval. At the time the 2009 Site Plan is being finalized, FPL's analyses to determine what its proposed DSM Goals for 2010 – 2019 are a work in progress. Consequently, FPL's 2009 Site Plan is retaining essentially the same level of projected DSM additions as was presented in its 2008 Site Plan. However, this level of projected DSM additions is likely to change due to the DSM Goals work.

Once FPL's DSM Goals are established, FPL will then send its proposed DSM Plan, with which it plans to meet these DSM Goals, to the FPSC for approval. FPL currently anticipates that both its DSM Goals and DSM Plan for the 2010 – 2019 time period will be approved by the first Quarter of 2010. Therefore, FPL expects that both its new DSM Goals and DSM Plan will be addressed in FPL's 2010 Site Plan.

III.E Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV bulk transmission lines that must be certified under the Transmission Line Siting Act.

Table III.E.1: List of Proposed Power Lines

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (KV)	(7) Capacity (MVA)
FPL	St. Johns [1/]	Pringle	25	Jun-09	230	759
FPL	Manatee [2/]	BobWhite	30	Dec-12	230	1190

1/ Final order certifying the corridor was issued on April 21, 2006. This project will be completed in two phases. Phase I consists of 4 miles of new 230kV line (Pringle to Pellicer) and is scheduled to be completed by Dec-2009. Phase II consists of 21 miles of new 230kV line (St. Johns to Pellicer) and is scheduled to be completed by Dec-2013.

2/ Final order certifying the corridor was issued on November 6, 2008. This project consists of 30 miles of new 230kV line (Manatee to Bobwhite) and is scheduled to be completed by Dec-2012

In addition, there will be transmission facilities needed to connect several of FPL's committed capacity increases and additions to the system transmission grid. These transmission facilities for the committed capacity additions at the DeSoto solar photo-voltaic (PV) site, the West County Energy Center site Units 1, 2, and 3, the capacity increases (uprates) at the existing St. Lucie and Turkey Point nuclear sites, the Cape Canaveral and Riviera Beach conversions, and the new nuclear unit addition Turkey Point Unit 6, are described on the following pages.

Certain new generation additions will not need new transmission facilities. These generation additions include the Martin Next Generation Solar Energy Center and the Space Coast Next Generation Solar Energy Center. The Martin facility does not add any new generation capacity at the site and, therefore, no new transmission facilities are required. The Space Coast facility is an addition of 10 MW of PV generation that will be connected at distribution voltage at the Grissom substation. No new transmission facilities are needed.

In regard to the existing generating units that are projected to be placed on Inactive Reserve status beginning in 2009, there are no projected impacts to FPL's transmission system from these units because these units can be returned to active service with adequate notice.

III.E.1 Transmission Facilities for West County Energy Center (WCEC) Unit 1

The work required to connect West County Energy Center (WCEC) Unit 1 in 2009 to the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT) and one steam turbine (ST).
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 230 kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1-580 MVA), one for each CT, and one for the ST.
4. Add a new Bay #4 with three breakers at the Corbett 230 kV main switchyard. Connect one string buss from the collector yard and relocate the Alva 230 kV terminal from Bay #3 to new Bay #4.
5. Connect second collector string buss to Bay #3.
6. Add relays and other protective equipment.
7. Breaker replacements:
   Corbett Substation – Replace eight 230 kV breakers
   Ranch Substation – Replace five 138 kV breakers
   Levee Substation – Replace one 230 kV breaker
   Dade Substation – Replace two 138 kV breakers

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.E.2 Transmission Facilities for West County Energy Center (WCEC) Unit 2

The work required to connect West County Energy Center (WCEC) Unit 2 in 2009 to the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Construct two string busses to connect the collector busses and main switchyard to Corbett 500kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. At Corbett Substation, install one breaker and relocate Martin #2 500 kV line from Bay 2S to Bay 2N. Install one West County 500 kv string bus into Bay 2S.
5. At Corbett Substation, install one breaker and second West County 500 kV string bus into Bay 1S.
6. Add relays and other protective equipment.
7. Breaker replacements:
   Dade Substation – Replace one 138 kV breaker
   Levee Substation – Replace two 230 kV breakers
   Ranch Substation – Replace one 230 kV breaker

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.E.3 Transmission Facilities for DeSoto Next Generation Solar Energy Center

The work required to connect the Desoto Next Generation Solar Energy Center project in 2009 to the FPL grid is projected to be as follows:

I. Substation:

1. Build a new Sunshine 230/23 kV Substation on FPL's Keentown-Whidden 230 kV line to connect the solar PV arrays.
2. Add relays and other protective equipment.
3. Breaker replacements: None

II. Transmission:

1. Loop Keentown-Whidden 230 kV line approximately 0.5 miles to Sunshine Substation.

III.E.4 Transmission Facilities for West County Energy Center (WCEC) Unit 3

The work required to connect West County Energy Center (WCEC) Unit 3 in 2011 to the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Build new Sugar 230 kV Substation on WCEC site.
3. Construct two string busses to connect the collector busses and main switchyard to Sugar 230kV Substation.
4. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
5. At Corbett Substation relocate Germantown 230 kV line terminal from Corbett to Sugar Sub.
6. At Corbett Substation relocate Broward/Yamato 230 kV line terminal from Corbett to Sugar Sub.
7. At Corbett Substation install new Sugar 230 kV line terminal in Bay 2W.
8. At Corbett Substation, install one 5-ohm inductor on the 230 kV side of the 500/230 kV autotransformer.
9. Add relays and other protective equipment.

II. Transmission:

1. Relocate Germantown 230 kV line from Corbett to Sugar.
2. Relocate Broward/Yamato 230 kV line from Corbett to Sugar.
3. Construct one mile 230 kV 1190 MVA line from Sugar to Corbett.

III.E.5 Transmission Facilities for St. Lucie Units 1 & 2 Capacity Uprates

The work required to accommodate the St. Lucie Units 1 & 2 uprates in 2011 for Unit 1 and in 2012 for Unit 2 to the FPL grid is projected to be as follows:

I. Substation:

1. At Midway Substation replace two 230 kV breaker and eleven 230 kV disconnect switches, and six wave traps. Also upgrade associated jumpers, bus work and equipment connections.
2. At St. Lucie Switchyard replace twenty-six 230 kV disconnect switches and six wave traps.
3. Uprate the Unit 1A and 1B main step-up transformers to 635 MVA.
4. Uprate the spare main step-up transformer to 635 MVA to replace Unit 2A main step-up transformer.
5. Replace the Unit 2B main step-up transformer with a new one rated at 635 MVA.

II. Transmission:

1. Upgrade the existing string busses for both units 1 & 2 between the main step-up transformers and the switchyard with spacers between the conductors.
2. Upgrade the three existing St. Lucie-Midway 230 kV lines with spacers between the conductors to achieve a normal (continuous) rating of 2790 Amperes.
3. Overhead ground wire and grounding improvements.

III.E.6 Transmission Facilities for Turkey Point Units 3 & 4 Capacity Uprates

The work required to accommodate the Turkey Point Units 3 & 4 uprates in 2012 for Unit 3 and in 2012 for Unit 4 to the FPL grid is projected to be as follows:

I. Substation:

1. At Turkey Point Switchyard install two 5-Ohm series phase inductors combined with external shunt capacitors on the southeast and southwest 230 kV operating busses.
2. At Turkey Point Switchyard replace twelve 230 kV disconnect switches. Also upgrade associated jumpers, bus work and equipment connections.
3. Uprate the Unit 3 and Unit 4 main step-up transformers to 970 MVA.
4. Replace spare main step-up transformer with 970-1050 MVA transformer.
5. Add relays and other protective equipment.

II. Transmission:

1. Upgrade the existing string busses for both Units 3 & 4 between the main step-up transformers and the switchyard with spacers between the conductors.

III.E.7 Transmission Facilities for Cape Canaveral Next Generation Clean Energy Center (Conversion)

The work required to connect the Cape Canaveral Next Generation Clean Energy Center in 2013 to the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Construct two string busses to connect the collector busses to Cape Canaveral 230kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. At Cape Canaveral Switchyard replace eight 230 kV disconnect switches. Also upgrade associated jumpers, bus work and equipment connections.
5. Expand switchyard relay vault and add relays and other protective equipment.
6. Breaker replacements:
   Cape Canaveral Switchyard – Replace four 230 kV breakers.

II. Transmission:

1. Relocate the Cape Canaveral-Grissom 115 kV line.

III.E.8 Transmission Facilities for Riviera Beach Next Generation Clean Energy Center (Conversion)

The work required to connect the Riviera Beach Next Generation Clean Energy Center in 2014 to the FPL grid is projected to be as follows:

I. Substation:

1. Expand the Riviera 230 kV Switchyard five breakers to accommodate terminals for one combustion turbine (CT), and one steam turbine (ST).
2. Construct a new 138 kV Riviera Switchyard - five bays, fourteen breakers with terminals to connect two CT units and seven 138 kV lines.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. Add relays and other protective equipment.
5. At Ranch Substation add a new 230 kV bay 5 and upgrade bay 4 to 3000 Amperes.
6. Breaker replacements:
   Ranch Substation – Replace one 230 kV breaker
   Broward Substation – Replace one 230 kV breaker

II. Transmission:

1. Break the Indiantown-Riviera 230kV and extend each of the line segments south (approx 4 miles) to connect to the Ranch 230 kV Substation forming Indiantown-Ranch and a Ranch-Riviera 230 kV circuits.
2. Remove Corbett-Ranch #2 230 kV line at Ranch and:
   a. extend to meet the Cedar-Lauderdale 230 kV line N/S corridor (approx 10 miles).
3. Break Cedar -Corbett 230 kV (near Ranch Sub in Corbett-Jog section) and:
   a. extend Cedar side to Riviera, (Approx 15 miles) creating new Cedar-Riviera 230 kV.
   b. extend Corbett side to meet the Cedar-Lauderdale 230 kV N/S corridor (approx 10 miles).
4. Break Cedar-Lauderdale 230 kV (near 230 corridor running N/S)
   a. connect Cedar side to meet 3.b. to create a Cedar to Corbett 230 kV.
   b. connect Lauderdale side to meet 2.a. to create a Corbett to Lauderdale 230 kV.
5. Upgrade the existing IBM-Yamato 138 kV line to 1200 Amperes.
6. New underground 138 kV tie line between new Riviera 138 kV Switchyard and 560 MVA, 230/138 kV autotransformer in the expanded Riviera 230 kV Substation.
7. Relocate six existing 138 kV lines from existing Ranch 138 kV Switchyard to new Riviera 138 kV Switchyard.

III.E.9 Transmission Facilities for Turkey Point Nuclear Unit 6

The work required to connect the Turkey Point Nuclear Unit 6 in 2018 to the FPL grid is projected to be as follows:

I. Substation:

1. Build new Clear Sky 500/230kV Switchyard with six bays on the 230 kV section for generator main step-up transformer connection, reserve auxiliary transformer connections, four 230 kV line terminals, two autotransformers and two 500 kV line terminals.
2. At Turkey Point Switchyard add a new bay to accommodate the Turkey Point-Clear Sky 230 kV line terminal.
3. At Gratigny Substation install a second 230/138 kV autotransformer with one 230 kV breaker and one 138 kV breaker.
4. At Pennsuco Substation install a fourth line terminal to accommodate the Pennsuco-Clear Sky 230 kV line by converting the ring bus to a breaker and a half scheme and adding four 230 kV breakers.
5. At Davis Substation construct two new 230kV line terminals for the Clear Sky-Davis 230 kV line and the Davis-Miami 230 kV line with a switchable inductor to be installed on the Davis-Miami 230 kV line.
6. At Levee Substation expand 500 kV section to accommodate the two Levee-Clear Sky 500 kV lines.
7. At Andytown Substation install two 5-Ohm inductors combined with external shunt capacitors on the 230kV side of the 500/230 autotransformers (one per auto).
8. At Miami Substation expand the 230kV section to a double bus configuration and add a new 230kV line terminal for Davis line and replace one autotransformer.
9. At Flagami Substation install a small inductor on one end of the Flagami-Miami 230kV #2 circuit.
10. Breaker replacements:

    Flagami Substation – Replace five 230 kV breakers and three 138 kV breakers
    Miami Substation – Replace one 230 kV breaker and four 138 kV breakers
    Davis Substation - Replace two 230 kV breakers
    Dade Substation - Replace seven 230 kV breakers
    Court Substation – Replace one 138 kV breaker.

II. Transmission:

1. FPL will design and construct two 500 kV transmission lines from the new Clear Sky Substation to the existing FPL Levee 500 kV Substation switchyard. The lines will be approximately 43 miles long.
2. Construct a new Clear Sky-Davis 230 kV line (approximately 19 miles) with a rating of 2990 Amperes.
3. Construct a new Clear Sky-Pennsuco 230 kV line (approximately 52 miles) with a rating of 2990 Amperes.
4. Construct a new Davis-Miami 230 kV line (approximately 18 miles) with a rating of 2297 Amperes.
5. Construct a new Clear Sky-Turkey Point 230 kV line (approximately 0.5 miles) with a rating of 2990 Amperes.

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various renewable energy technologies. For purposes of discussing FPL's renewable energy efforts in this document, those efforts will be placed into five categories.

1) **Early Research & Development Efforts:**

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970s in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities in Florida on both a daily and annual basis. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-kilowatt (kW) system was placed into operation in 1984. (The system was removed in 1990 to make room for substation expansion after the testing of this PV installation was completed.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed below).

2) **Demand Side & Customer Efforts:**

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was no longer cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980s, FPL introduced another renewable energy program, FPL's Passive Home Program. This program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for 6 passive homes with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the FPSC to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test were deemed to be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

FPL then analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach did not require all of its customers to bear the high cost of PV, but facilitated the use of renewable energy by customers who were interested. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund that FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid, thus displacing an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach for this program, which was termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL began the effort in 1998 and received approximately $89,000 in contributions (that significantly exceeded the goal of $70,000). FPL purchased the PV modules and installed them at FPL's Martin Plant site.

FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was FPL's Photovoltaic Research, Development, and Education Project. This demonstration project's objectives were to: increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks (as well as the total annual energy capabilities of roof tile PV systems), and assess the homeowner's financial benefits and costs of PV roof tile systems. This project was completed in 2003.

The second effort initiated in 2000 was the Green Energy Project. The objectives of this Project were to: determine customer interest in an on-going renewable energy program, determine their price responsiveness and views on the different renewable technologies, and identify potential renewable energy supply sources that would meet the forecasted customer demand for this type of product. This Project formed the basis for FPL's Green Power Pricing Research Project, and then led to FPL's Business Green Energy Research Project.

Both the Green Power Pricing Research Project and the Business Green Energy Research Project examined the feasibility of purchasing tradable renewable energy credits generated from renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable sources. Customers who participate are charged a premium for purchasing the tradable renewable energy credits associated with electric energy generated by these sources.

Development of the Green Pricing Research Project was completed and filed with the FPSC in August 2003. As part of this process, a supply contract was put into place that allowed FPL to match supply with demand for green energy. Tradable renewable energy credits were used to supply the renewable benefits required of this project. The FPSC approved the program in December 2003 and program implementation began during the first Quarter of 2004. The project was offered to customers as FPL's Sunshine Energy® program. As part of the project, FPL made a commitment that 150 kilowatts (kW) of solar capacity would be put in place for every 10,000 program participants. The Business Green Energy Research Project focused on determining the interest and needs for business customers in this area. In 2006 FPL petitioned the FPSC for approval to make the Green Pricing Research Project a permanent program and expand eligibility to business customers. This approval was granted in the fourth Quarter of 2006.

As Florida entered the next phase in promotion of renewable energy, with FPL requesting approval to build three new solar energy centers in the state (which are discussed below), in 2008 the FPSC voted to end the Sunshine Energy program. At its conclusion, the Sunshine Energy Program included approximately 38,000 participants and resulted in 494 kW of PV installed, including the largest PV array in the state at that time, a 250 kW facility at Rothenbach Park in Sarasota County. Several additional solar initiatives had also been developed through the Sunshine Energy Program including support for schools. The Sunshine Energy Program support of installing PV at schools was a continuation of previous FPL renewable activities involving schools. In 2003, as part of the State of Florida's PV for Schools program, FPL worked with three schools to install 4.8 kW of PV systems.

FPL has also been investigating fuel cell technologies through monitoring of industry trends, discussions with manufacturers, and direct field trials. From 2002 through the end of 2005, FPL conducted field trials and demonstration projects of Proton Exchange Membrane (PEM) fuel cells with the objectives of serving customer end-uses while evaluating the technical performance, reliability, economics, and relative readiness of the PEM technology. The demonstration projects were conducted in partnership with customers and included 5 locations. The research projects were useful to FPL in identifying specific issues that can occur in field applications and the current commercial viability of this technology. FPL will continue to monitor the progress of these technologies and conduct additional field evaluations as significant developments in the fuel cell technologies occur.

In addition, FPL assists customers who are interested in installing PV equipment at their facilities. In support of Florida Administrative Code Rule 25-6.065, Interconnection and Net Metering of Customer-Owned Renewable Generation, FPL works with customers to interconnect these customer-owned PV systems. Through December 2008, approximately 270 customer systems (predominantly residential) have been interconnected.

3) <u>Supply Side Efforts – Power Purchases:</u>

FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy and as-available energy have been purchased by FPL from these types of facilities. (Please refer to Tables I.B.1, I.B.2, and Table I.C.1 in Chapter I).

FPL is seeking cost-effective Power Purchase Agreements (PPAs) with any and all potential renewable energy providers. FPL issued a Renewable Request for Proposals (RFP) in 2007 that solicited proposals that offered capacity and/or energy from new renewable energy facilities. None of the responsive bids in this RFP were at or below FPL's projected avoided cost. FPL issued another Renewable Energy RFP in April 2008, which resulted in six bids received by July. Analysis of the bids was delayed by the extreme volatility in the commodity fuel and capital markets in late 2008. Current analysis indicates that none of the bids may have the potential to provide firm capacity and/or energy at avoided cost prices (and the FPSC has ruled that costs above FPL's projected avoided costs cannot be recovered for purchase contracts).

With regard to certain of the existing contracts that are currently scheduled to end in the near-term, and proposals resulting from the RFP process, FPL has assumed that some of this firm capacity will be available during the ten-year reporting period of this document through extended and/or new contracts. Firm renewable energy capacity from these sources, and from the FPL development activities discussed below, are assumed for planning purposes to provide 105 MW through this reporting period. 55 MW of the 105 MW total is expected to come from an extension of an existing purchased power contract that will expire soon. The remaining 50 MW are projected, for planning purposes, to come from a new purchase power contract (but could be delivered by a new FPL renewable energy facility).

4) <u>Supply Side Efforts – FPL Facilities:</u>

FPL is in the process of developing a wind generation project on South Hutchinson Island in St. Lucie County. This project is known as the St. Lucie Wind project and it consists of up to 6 wind turbine generators capable of generating up to approximately 13.8 MW. In 2007, FPL began the St. Lucie County land use approval process, and soon after applied for the necessary federal and state permitting. However, a decision by the state and federal agencies on the St. Lucie Wind project's permitting will not be finalized until the local land use approval process is completed. The in-service date will depend on the approval and permitting process.

FPL is currently constructing 110 MW of solar capacity at three sites in Florida. These projects are in response to the Florida's Legislature House Bill 7135 which was signed into law by Governor Crist in June 2008. House Bill 7135 (hereafter referred to as the 2008 Energy Bill), was enacted to enable the development of clean, zero greenhouse gas emitting renewable generation in State of Florida. Specifically, the 2008 Energy Bill authorized cost recovery for the first 110 MW of eligible renewable projects that had the proper land, zoning and transmission rights in place. FPL's three solar projects discussed in this section met the specified criteria, and were granted approval for cost recovery in 2008. Each of the three solar projects is discussed below.

a. **The Martin Next Generation Solar Energy Center:**
This project will provide 75 MW of solar thermal capacity in an innovative way that directly displaces fossil fuel usage in an existing FPL generating unit. This project will involve the installation of solar thermal technology that will be integrated into the existing steam cycle for the Martin Unit 8 natural gas-fired CC plant. This project will be the first "hybrid" solar plant in the world, the second largest solar facility in the world, and the largest solar plant of any kind in the U.S. outside of California. Construction began in December 2008 and is expected to be completed by the end of 2010.

b. **The DeSoto Next Generation Solar Energy Center:**
This project will provide 25 MW of photovoltaic (PV) capacity, making it the largest PV facility in the U.S.. The facility will utilize a tracking array that is designed to follow the sun as it traverses through the sky. Construction began in November 2008 and is expected to be completed by the end of 2009 or early 2010.

c. **The Space Coast Next Generation Solar Energy Center:**
This project will provide 10 MW of PV capacity in an innovative public/private partnership with NASA at the Kennedy Space Center. Construction is expected to begin in 2009 and is expected to be completed in 2010.

Each of these facilities is a significant and innovative renewable generating plant in its own right. Collectively, these Next Generation Solar Energy Centers are expected to produce a total of 223,000 megawatt hours (MWh) of electricity each year, and at peak production provide enough power and energy to serve the requirements of more than 15,000 homes.

For resource planning purposes, FPL projects that the energy delivered from these renewable facilities will be "as available", non-firm energy. This is due to several factors. First, the Martin solar thermal facility is designed as a "fuel-substitute" facility, not as a facility that will result in additional capacity and energy being generated. The solar thermal facility will displace the use of fossil fuel on the FPL system when the solar thermal facility is operating. Second, in regard to the two PV facilities, the intermittent nature of the solar resource makes it difficult to accurately determine what contribution the PV facilities at these specific locations can consistently make at FPL late Summer afternoon and early Winter morning peak load hours. Once site-specific operating data has been gathered for an appropriate amount of time, FPL will then re-evaluate the actual output from each PV facility to determine what portion, if any, of its output can be projected as firm capacity at the projected peak hours in FPL's resource planning work.

In addition to these three approved projects; FPL is currently in the process of identifying other potential solar sites in the state in the event that a future Renewable Portfolio Standard (RPS) or other enabling legislation is enacted by the Florida legislature. FPL is evaluating existing FPL generation sites along with potential greenfield sites within FPL's service territory. Sites which are considered potential candidates will be developed so that the necessary local land use and zoning designations are consistent with the future development of solar generation. Sites that have been identified for further evaluation include the potential expansion of the DeSoto site for additional PV, and the expansion of the Manatee site for a solar thermal facility. These sites are discussed further in Chapter IV.

5) **<u>Ongoing Research & Development Efforts:</u>**

FPL has developed alliances with several Florida universities to promote development of emerging technologies. For example, an alliance as been established with the newly formed Center for Ocean Energy Technology at Florida Atlantic University (FAU), which will focus on the commercialization of ocean current, ocean thermal (i.e., energy conversion as well as cold water air conditioning) and hydrogen technologies. FPL has been taking the lead in assisting FAU with the discussions being held with the U.S. Department of the Interior's Minerals

Management Service Department (MMS). MMS is working to establish the permitting process for ocean energy development on the outer continental shelf.

FPL has also developed an alliance with the University of Florida to support its studies of biomass renewable potential and wind studies in the state. In addition, FPL has partnered with the Florida Institute of Technology on fuel cell technology and with the Florida State Universities Center for Applied Power System in regard to grid integration of ocean energy and other renewables.

FPL is also developing a "living lab" to demonstrate FPL's solar energy commitment to employees and visitors at its Juno Beach facility. FPL will evaluate multiple solar technologies and applications to develop a renewable business model resulting in the most cost-effective and reliable source(s) of solar energy to FPL customers.

FPL has also been in discussion with several private companies on multiple emerging technology initiatives including ocean current, ocean thermal, hydrogen, fuel cell technology, biomass, biofuels, and energy storage.

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980s, FPL relied primarily on a combination of fuel oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil–fired generation. In the early 1980s, FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit 4 which began serving FPL's customers in 1991. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP.

The trend since the early 1990s has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective CC generating units and the ready availability of natural gas. This planning document reflects an evolution in that trend in recognition that, although efficient gas-fired generation continues to provide significant benefits to FPL's customers, adding natural gas-fired additions exclusively would, in the long term, create an unbalanced generation portfolio. FPL has committed to add three new gas-fired CC units at the West County Energy Center (WCEC) site in the 2009 – 2011 time frame. In addition, FPL has also committed to convert the existing steam generating units at its existing Cape Canaveral and Riviera sites into two highly efficient new CC units, one at each site. These five new CC units will provide highly efficient generation that will dramatically improve FPL's overall system generation efficiency.

In addition, FPL is increasing its utilization of nuclear energy through capacity uprates of its four existing nuclear units. These uprates will add a total of approximately 400 MW of nuclear generation capacity by 2012. FPL has also received approval from the FPSC to pursue plans to permit and build two new nuclear units at its existing Turkey Point site that, in total, will add approximately 2,200 MW of new nuclear generating capacity. The first of these two new units, Turkey Point Unit 6, is projected to go in-service in 2018 and is presented in this document. The second new nuclear unit, Turkey Point Unit 7, is projected to have a 2020 in-service date and will be presented in future FPL Site Plans.

In regard to utilizing renewable energy, FPL has committed to add 110 MW of solar generating capacity by 2010 through a 75 MW solar thermal facility at FPL's existing Martin site, a 25 MW PV facility in DeSoto County, and a 10 MW PV facility in Brevard County.

FPL's future resource planning work will continue to focus on identifying and evaluating alternatives that would maintain and/or enhance FPL's long-term fuel diversity. These fuel diverse alternatives may include: the purchase of power from renewable energy facilities, addition of FPL-owned renewable energy facilities, obtaining access to diversified sources of natural gas such as liquefied natural gas (LNG) and natural gas from the newly developed Mid-Continent unconventional reserves, preserving FPL's ability to utilize fuel oil at its existing units, and increased utilization of nuclear energy. (New advanced technology coal generating units are not currently considered as viable options in Florida in the ten-year reporting period of this document due to concerns over greenhouse gas emissions.) The evaluation of the feasibility and cost-effectiveness of these, and other possible alternatives, will be an ongoing part of future planning cycles.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2018 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

2. Fossil Fuel Price Forecasts

Fossil fuel price forecasts, and the resulting projected price differentials between fuels, are major drivers used in evaluating alternatives for meeting future generating capacity needs. FPL's forecasts are generally consistent with other published contemporary forecasts.

Future oil and natural gas prices, and to a lesser extent, coal and petroleum coke prices, are inherently uncertain due to a significant number of unpredictable and uncontrollable drivers that influence the short-and long-term price of oil, natural gas, coal, and petroleum coke. These drivers include:

a. Current and projected worldwide demand for crude oil and petroleum products;

b. Current and projected worldwide refinery capacity/production;

c. Expected worldwide economic growth, in particular in China, India, and the other Pacific Rim countries;

d. Organization of Petroleum Exporting Countries (OPEC) production and the availability of spare OPEC production capacity and the assumed growth in spare OPEC production capacity;

e. Non-OPEC production and expected growth in non-OPEC production;

f. The geopolitics of the Middle East, West Africa, the Former Soviet Union, Venezuela, etc., as well as, the uncertainty and impact upon worldwide energy consumption related to U. S. and worldwide environmental legislation, politics, etc.;

g. Current and projected North American natural gas demand;

h. Current and projected U.S., Canadian, and Mexican natural gas production;

i. The worldwide supply and demand for LNG; and

j. The growth in solid fuel generation on a U. S. and worldwide basis.

The inherent uncertainty and unpredictability in these factors today and tomorrow clearly underscores the need to develop a set of plausible oil, natural gas, and solid fuel (coal and petroleum coke) price scenarios that will bound a reasonable set of long-term price outcomes. In this light, FPL developed and utilized Low, Medium, and High price forecasts for oil, natural gas, and solid fuel in much of its 2008 resource planning work, particularly in regard to the Determination of Need filings for WCEC Unit 3 and the conversions of FPL's existing Cape Canaveral and Riviera plants, and the nuclear cost recovery filings.

FPL's Medium price forecast methodology is consistent for oil and natural gas. For oil and natural gas commodity prices, FPL's Medium price forecast applies the following methodology:

a. For 2008 through 2010, the methodology used the November 6, 2008 forward curve for New York Harbor 1% sulfur heavy oil, U. S. Gulf Coast 1% sulfur heavy oil, ultra low sulfur diesel, and Henry Hub natural gas commodity prices;

b. For the next two years (2011 and 2012), FPL used a 50/50 blend of the November 6, 2008 forward curve and the most current projections at the time from The PIRA Energy Group;

c. For the 2013 through 2020 period, FPL used the annual projections from The PIRA Energy Group, and;

d. For the period beyond 2020, FPL used the real rate of escalation provided in the Energy Information Administration (EIA) *Annual Energy Outlook 2008* publication. FPL assumed a 2.5% annual rate of escalation to convert real prices to nominal prices prior to 2020, with no escalation from 2020 forward. In addition to the development of oil and natural gas commodity prices, nominal price forecasts also were prepared for oil and natural gas transportation costs. The addition of commodity and transportation forecasts resulted in delivered price forecasts.

FPL's Medium price forecast methodology is also consistent for coal and petroleum coke prices. Coal and petroleum coke prices were based upon the following approach:

a. The price forecasts for Central Appalachian coal (CAPP), South American coal, and petroleum coke were provided by JD Energy;

b. The marine transportation rates from the loading port for coal and petroleum coke to an import terminal were also provided by JD Energy;

c. The Terminal Throughput Fee was based on a range of offers from comparable facilities throughout the Southeast U.S.. The coal price forecast for FPL's existing coal plants at SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements.

The development of FPL's Low and High price forecasts for oil, natural gas, coal, and petroleum coke prices were based upon the historical relationship of prices compared to the average prices for the 2000 through 2007 time frame. FPL developed these forecasts to account for the uncertainty which exists within each commodity as well as across commodities. These forecasts reflect a range of reasonable forecast outcomes.

3. Nuclear Fuel Cost Forecast

This section reviews the various steps needed to fabricate nuclear fuel for delivery to the nuclear power plants, the method used to forecast the price for each step, and other comments regarding FPL's nuclear fuel cost forecast.

a) Steps Required for Nuclear Fuel to be delivered to FPL's Plants

Four separate steps are required before nuclear fuel can be used in a commercial nuclear power reactor. These steps are summarized below.

(1) Mining: Uranium is produced in many countries such as Canada, Australia, Kazakhstan, and the United States. During the first step, uranium is mined from the ground using techniques such as open pit mining, underground mining, in-situ leaching operations, or production as a by-product from other mining operations, such as gold, copper, or phosphate rocks. The product from this first step is the raw uranium delivered as an oxide, U3O8 (sometimes referred to as yellowcake).

(2) Conversion: During the second step, the U3O8 is chemically converted into UF6 which, when heated, changes into a gaseous state. This second step further removes any chemical impurities and serves as preparation for the third step, which requires uranium to be in a gaseous state.

(3) **Enrichment:** The third step is called enrichment. Natural uranium contains 0.711% of uranium at an atomic mass of 235 (U-235) and 99.289% of uranium at an atomic mass of 238 (U-238). FPL's nuclear reactors use uranium with a higher percentage of up to five percent (5%) of U-235 atoms. Because natural uranium does not contain a sufficient amount of U-235, the third step increases the percentage amount of U-235 from 0.711% to a level specified when designing the reactor core (typically in a range from approximately 3% to as high as 5%). The output of this enrichment process is enriched uranium in the form of UF6.

(4) **Fabrication:** During the last step, fuel fabrication, the enriched UF6 is changed to a UO2 powder, pressed into pellets, and fed into tubes, which are sealed and bundled together into fuel assemblies. These fuel assemblies are then delivered to the plant site for insertion in a reactor.

Like other utilities, FPL has purchased raw uranium and the other components of the nuclear fuel cycle separately from numerous suppliers from different countries.

b) Price Forecasts for Each Step

(1) **Mining:** There is a significant volatility in the current uranium market. Demand is rather stable but inventory sales are a significant source of supply to complement outputs from production facilities. To the extent that source of supply can be restricted and inventories held from the market, price will rise significantly. The following are the current major contributors to this uranium price volatility:

- Hedge funds have been purchasing a significant amount of uranium, reducing availability of uranium. However, the recent financial crisis has caused significant sales of inventories and has caused the market to drop earlier than predicted.

- The large inventory from the U.S. Department of Energy (DOE) is being withheld from the market due to political pressure from suppliers concerned about further price drop already affected by the current financial downturn.

- The Russians have announced that they would not supply down-blended weapons material to the U.S. government after 2013 for sale in the U.S. market.

- The U.S. Department of Commerce (DOC) has imposed restrictions on the import of nuclear fuel from France and Russia.

However, FPL expects these issues to be addressed within the next few years, returning price behavior to be more consistent with market fundamentals. 2008 saw a number of actions to resolve restrictions of imports of foreign uranium. Recent law enacted in 2008 resolved the import of Russian-enriched uranium, by allowing some imports of Russian-enriched uranium to about 20-25% of needs for currently operating units, but with no restriction on the first core for new units and no restrictions after 2020. The financial crisis has also had a major impact and eliminated speculative demands with uranium pricing returning to close to the fundamentals earlier than was expected last year. The hedge funds have significantly reduced their activities.

FPL's nuclear fuel price forecasts are the result of FPL's analysis based on inputs from various nuclear fuel market expert reports and studies.

(2) Conversion: FPL's price forecast considers the construction of new nuclear units. Just like for raw uranium, an increase in demand for conversion services would result from this need. Insufficient planned production is currently forecast after 2013 to meet the higher demand scenario. As with additional raw uranium production, supply will expand beyond current level once more firm commitments are made including commitments to building new nuclear units.

(3) Enrichment: With no new production capacity, and if the current restrictions on imports of enrichment services from Russia continue, the current tight market supply for economically produced enrichment services will continue until 2013. A high projection of new nuclear unit construction shows a shortage of low cost enrichment services starting in 2010. The current expensive diffusion plant can make up any gaps in supply of enrichment services. In addition, there are a number of new facilities coming on-line starting in 2009 through 2013, using more efficient and proven processes such as the use of centrifuges for enrichment of uranium. In addition, as with supply for the other steps of the nuclear fuel cycle, expansion of future capacity is feasible within the lead time for constructing new nuclear units and any other projected increase in demand.

(4) Fabrication: Because the nuclear fuel fabrication process is highly regulated by the Nuclear Regulatory Commission (NRC), not all production facilities can qualify as suppliers to nuclear reactors in the U.S. Although world supply and demand is expected to show significant excess capacity for the foreseeable future, the gap is not as wide for U.S. supply and demand. The supply for the U.S. market is expected to be sufficient to meet U.S. demand for the foreseeable future.

c) Other Comments Regarding FPL's Nuclear Fuel Cost Forecast

The calculations for the nuclear fuel costs are performed consistent with the method currently used for FPL's Fuel Clause filings, including the assumption of a fuel lease and the assumption of refueling outages every 18 months. The costs for each step to fabricate the nuclear fuels are added and capitalized to come up with the total costs of the fresh fuel to be loaded at each refueling (capitalized acquisition costs). The capitalized acquisition cost for each group of fresh fuel assemblies are then amortized over the energy produced by each group of fuel assemblies, and carrying costs are also added on the total unrecovered costs to derive the total fuel costs to be charged to customers. FPL also adds 1 mill per kilowatt hour net to reflect payment to DOE for spent fuel disposal.

Schedule 5
Fuel Requirements 1/

								2009 Changes/Additions with Inactive Reserve Total:				(78)	(96)	

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All MW additions/changes occuring later in the year will be picked up for reporting/planning purposes in the following year.

Note 2: Changes shown may include different ratings than shown in Schedule 1 due solely to ambient temperature consistent with those in FPL 's peak load forecast to maintain consistency in reserve margin calculations.

Note 3: The Photovoltaic MWs are not included in the total at this time because these facilities are assumed to provide non-firm energy only.

								2011 Changes/Additions with Inactive Reserve Total:				(2,327)	1,125	

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All MW additions/changes occuring later in the year will be picked up for reporting/planning purposes in the following year.

Note 2: Changes shown may include different ratings than shown in Schedule 1 due solely to ambient temperature consistent with those in FPL 's peak load forecast to maintain consistency in reserve margin calculations.

Note 3: The Photovoltaic MWs are not included in the total at this time because these facilities are assumed to provide non-firm energy only.

											2018 Changes/Additions with Inactive Reserve Total:	834	1,100	

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All MW additions/changes occuring later in the year will be picked up for reporting/planning purposes in the following year.

Note 2: Changes shown may include different ratings than shown in Schedule 1 due solely to ambient temperature consistent with those in FPL 's peak load forecast to maintain consistency in reserve margin calculations.

Note 3: The nuclear uprates will be performed during the scheduled refueling outages for each unit.

Note 4. Certain existing FPL units that have been placed on temporarily on Inactive Reserve status are assumed, for planning purposes in this document, to being returning to active reserve starting in 2016.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** West County Energy Center Combined Cycle Unit 1

(2) **Capacity**
a. Summer 1,219 MW
b. Winter 1,335 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2007
b. Commercial In-service date: 2009

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 220 Acres

(9) **Construction Status:** V (Under construction, more than 50% complete)

(10) **Certification Status:** V (Under construction, more than 50% complete)

(11) **Status with Federal Agencies:** V (Under construction, more than 50% complete)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 90%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582	Btu/kWh (Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	25	years
Total Installed Cost (2009 $/kW):	565	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):	55	
Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2009 $kW-Yr)	11.65	
Variable O&M ($/MWH): (2009 $/MWH)	0.138	
K Factor:	1.5834	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** West County Energy Center Combined Cycle Unit 2

(2) **Capacity**
a. Summer 1,219 MW
b. Winter 1,335 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2008
b. Commercial In-service date: 2009

(5) **Fuel**
a. Primary Fuel — Natural Gas
b. Alternate Fuel — Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 220 Acres

(9) **Construction Status:** V (Under construction, more than 50% complete)

(10) **Certification Status:** V (Under construction, more than 50% complete)

(11) **Status with Federal Agencies:** V (Under construction, more than 50% complete)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 88%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582 Btu/kWh	(Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data **,*****

Book Life (Years):	25 years
Total Installed Cost (2010 $/kW):	519
Direct Construction Cost ($/kW):	
AFUDC Amount ($/kW):	57
Escalation ($/kW):	
Fixed O&M ($/kW -Yr.): (2010 $kW-Yr)	10.11
Variable O&M ($/MWH): (2010 $/MWH)	0.138
K Factor:	1.5873

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** DeSoto Next Generation Solar Energy Center

(2) **Capacity**
a. Summer 25 MW
b. Winter 25 MW

(3) **Technology Type:** Photovoltaic

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2009
b. Commercial In-service date: 2010

(5) **Fuel**
a. Primary Fuel Solar
b. Alternate Fuel N/A

(6) **Air Pollution and Control Strategy:** N/A

(7) **Cooling Method:** N/A

(8) **Total Site Area:** 180 Acres

(9) **Construction Status:** U (Under construction, less than 50% complete)

(10) **Certification Status:** Pemitted (Individual Permits)

(11) **Status with Federal Agencies:** Permitted

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	N/A
Forced Outage Factor (FOF):	N/A
Equivalent Availability Factor (EAF):	0.98
Resulting Capacity Factor (%):	Approx. 25% (First Full Year of Operation)
Average Net Operating Heat Rate (ANOHR):	N/A Btu/kWh
Base Operation 75F,100%	

(13) **Projected Unit Financial Data *,****

Book Life (Years):	25 years
Total Installed Cost (2010 $/kW):	6,937
Direct Construction Cost ($/kW):	-
CWIP Amount ($/kW):	369
Escalation ($/kW):	-
Fixed O&M ($/kW -Yr.): (2010 $kW-Yr)	54
Variable O&M ($/MWH): (2010 $/MWH)	0
K Factor:	1.15

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement.

NOTE: Total installed cost includes transmission interconnection.

Schedule 9

a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 220 Acres

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 93%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582	Btu/kWh (Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data **,*****

Book Life (Years):	25	years
Total Installed Cost (2011 $/kW):	709	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):	71	
Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2011 $kW-Yr)	11.63	
Variable O&M ($/MWH): (2011 $/MWH)	0.480	
K Factor:	1.4697	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** St. Lucie 1 Nuclear Uprate

(2) **Capacity**
a. Summer 103 MW (Incremental)
b. Winter 103 MW (Incremental)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2011

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel ---

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	No change from existing unit
Forced Outage Factor (FOF):	No change from existing unit
Equivalent Availability Factor (EAF):	No change from existing unit
Resulting Capacity Factor (%):	No change from existing unit
Average Net Operating Heat Rate (ANOHR):	No change from existing unit
Base Operation 75F,100%	No change from existing unit

(13) **Projected Unit Financial Data** *

Book Life (Years):	25	years (Matches the current operating license period.)
Total Installed Cost ($/kW): **	3,054	(See Note (1) for explanation.)
Direct Construction Cost:	3,054	(See Note (1) for explanation.)
AFUDC Amount ($/kW):		(See Note (2) for explanation.)
Escalation ($/kW):		(See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.):	There is no additional O&M impact from this project.	
Variable O&M ($/MWH):	There is no additional O&M impact from this project.	
K Factor:		(See Note (2) for explanation.)

NOTE:
(1) This value does not include a plant-specific portion of the early recovery of approx. $353 million of capital carrying costs in total associated with the uprates at the four existing nuclear units, nor a plant-specific portion of a projected $45 million in total for transmission costs associated with the uprates at the four existing nuclear units.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

* $/kW values are based on incremental Summer capacity.
** $/incremental kW

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Turkey Point 3 Nuclear Uprate

(2) **Capacity**
a. Summer 104 MW (Incremental)
b. Winter 104 MW (Incremental)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2012

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel ---

(6) **Air Pollution and Control Strategy:** No change from existing unit

** $/incremental kW

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** St. Lucie 2 Nuclear Uprate

(2) **Capacity**
a. Summer 103 MW (Total Incremental), 88 MW (incremental FPL's ownership share)
b. Winter 104 MW (Total Incremental), 88 MW (incremental FPL's ownership share)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2012

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel --

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**
Planned Outage Factor (POF): No change from existing unit
Forced Outage Factor (FOF): No change from existing unit
Equivalent Availability Factor (EAF): No change from existing unit
Resulting Capacity Factor (%): No change from existing unit
Average Net Operating Heat Rate (ANOHR): No change from existing unit
Base Operation 75F,100% No change from existing unit

(13) **Projected Unit Financial Data *,****
Book Life (Years): 31 years (Matches the current operating license period.)
Total Installed Cost ($/kW): ** 3,271 (See Note (1) for explanation.)
Direct Construction Cost ($/kW): 3,271 (See Note (1) for explanation.)
AFUDC Amount ($/kW): (See Note (2) for explanation.)
Escalation ($/kW): (See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.): There is no additional O&M impact from this project.
Variable O&M ($/MWH): There is no additional O&M impact from this project.
K Factor: (See Note (2) for explanation.)

NOTE:
(1) This value does not include a plant-specific portion of the early recovery of approx. $353 million of capital carrying costs in total associated with the uprates at the four existing nuclear units, nor a plant-specific portion of a projected $45 million in total for transmission costs associated with the uprates at the four existing nuclear units.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

* $/kW values are based on incremental Summer capacity.
** $/incremental kW

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Turkey Point 4 Nuclear Uprate

(2) **Capacity**
a. Summer 104 MW (Incremental)
b. Winter 104 MW (Incremental)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2012

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel ---

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	No change from existing unit
Forced Outage Factor (FOF):	No change from existing unit
Equivalent Availability Factor (EAF):	No change from existing unit
Resulting Capacity Factor (%):	No change from existing unit
Average Net Operating Heat Rate (ANOHR):	No change from existing unit
Base Operation 75F,100%	No change from existing unit

(13) **Projected Unit Financial Data *,****

Book Life (Years):	22	years (Matches the current operating license period.)
Total Installed Cost ($/kW): **	3,630	(See Note (1) for explanation.)
Direct Construction Cost ($/kW):	3,630	(See Note (1) for explanation.)
AFUDC Amount ($/kW):		(See Note (2) for explanation.)
Escalation ($/kW):		(See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.):	There is no additional O&M impact from this project.	
Variable O&M ($/MWH):	There is no additional O&M impact from this project.	
K Factor:		(See Note (2) for explanation.)

NOTE:
(1) This value does not include a plant-specific portion of the early recovery of approx. $353 million of capital carrying costs in total associated with the uprates at the four existing nuclear units, nor a plant-specific portion of a projected $45 million in total for transmission costs associated with the uprates at the four existing nuclear units.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

West County Energy Center Unit 1

The new West County Energy Center Unit 1 does not require any "new" transmission lines.

Schedule 10

Status Report and Specifications of Proposed Transmission Lines

West County Energy Center Unit 2

The new West County Energy Center Unit 2 does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Desoto Next Generation Solar Energy Center (PV)

The new Desoto Next Generation Solar Energy Center (PV) does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Space Center Next Generation Solar Energy Center (PV)

The new Space Center Next Generation Solar Energy Center (PV) does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

West County Energy Center Unit 3

(1)	Point of Origin and Termination:	New Sugar Substation – Corbett Substation
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	1 mile
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: May 2009 End date: November 2010
(7)	Anticipated Capital Investment: (Trans. and Sub.)	$11,300,000
(8)	Substations:	New Sugar Substation and Corbett Substation
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

St. Lucie 1 Nuclear Uprate

The St. Lucie 1 Nuclear Uprate does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point 3 Nuclear Uprate

The Turkey Point 3 Nuclear Uprate does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

St. Lucie 2 Nuclear Uprate

The St. Lucie 2 Nuclear Uprate does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point 4 Nuclear Uprate

The Turkey Point 4 Nuclear Uprate does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Cape Canaveral Next Generation Clean Energy Center (Conversion)

The Cape Canaveral Next Generation Clean Energy Center, that is the result of the conversion of the exiting Cape Canaveral power plant site, does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Riviera Beach Next Generation Clean Energy Center (Conversion)

The Riviera Beach Energy Center Conversion, that is the result of the conversion of the existing Riviera Beach power plant site, does not require any "new" transmission lines. Several lines will be extended and reconfigured to accommodate the increased capacity.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point Unit 6

(1)	Point of Origin and Termination:	New Clear Sky Substation – Levee Substation
(2)	Number of Lines:	2

Note:
(1) FPL Existing Units Total of 22,087 MW matches Total System found on Schedule 1.
(2) Net Energy for Load GWH of 111,004 GWH matches Schedule 6.1

Schedule 11.2

Existing NON-FIRM Self-Service Renewable Generation Facilities
Actuals for the Year 2008

(1)	(2)	(3)	(4)	(5)	(6) = (3+4)-(5)
Type of Facility	**Installed Capacity (MW)**	**Projected Annual Output (MWH)**	**Annual Energy Purchased from FPL (MWH)**	**Annual Energy Sold to FPL (MWH)**	**Projected Annual Energy Used by Customer (MWH)**
Customer-Owned PV (less than or equal to 10 kw AC)	0.839	900	33,220	153	33,967
Customer-Owned PV greater than 10 kw and less than or equal to 100 kw AC	0.233	192	558	15	735
Total:	**1.072**	**1,092**	**33,777**	**167**	**34,702**

Notes:

(1) There were approximately 262 customer-owned operating PV facilities interconnected with FPL during 2008.
(2) The Installed Capacity value is the sum of the nameplate ratings (AC kw) for all of the customer-owned PV facilities.
(3) The Projected Annual Output value is based on NREL's PV Watts program and the Installed Capacity value in column (2), adjusted for the date when each facility was installed and assuming each facility operated as planned.
(4) The Annual Energy Purchased from FPL is an actual value from FPL's metered data for 2008.
(5) The Annual Energy Sold to FPL is an actual value from FPL's metered data for 2008.
(6) The Projected Annual Energy Used by Customers is a projected value that is the difference between the (Projected Annual output + Annual Output value in column (2) and the actual Annual Energy Sold to FPL in column (4).

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered or threatened plant and animal species. FPL competes for air, land, and water resources that are necessary to meet the demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among electric utilities for its commitment to the environment. FPL's environmental leadership has been heralded by many outside organizations as demonstrated by a few recent examples. For the second time (2007 and 2008), FPL Group is ranked first among electric and gas utilities in FORTUNE ® magazine's, "America's Most Admired Companies" edition. FPL scored number one in each of the eight attributes considered: innovation, people management, use of corporate assets, social responsibility, quality of management, financial soundness, long-term investments, and quality of products and services.

In May 2007, FPL Group was included on the KLD Global Climate 100SM Index for the third time since the Global Climate 100 was launched in 2005. The Global Climate 100 is designed to promote investment in public companies whose activities demonstrate the greatest potential for reducing the social and economic consequences of climate change. The Global Climate 100 Index includes a mix of 100 global companies that demonstrate leadership in providing near term solutions to climate change through renewable energy, alternative fuels, clean technology, and efficiency.

In January 2007, FPL Group was named one of the Global 100 Most Sustainable Corporations in the World by Corporate Knights, Inc., a Canadian media company. Some 1,800 companies from a wide range of sectors were evaluated regarding effective management of environmental, social, and governance risks and opportunities. FPL Group was one of the only two United States utility companies to make the list of 100.

FPL Group is one of America's cleanest energy providers and the emissions rates of FPL's power plants are among the lowest in the electric industry. FPL's environmental achievements were reflected by its No. 1 environmental ranking, for five consecutive years, in the Innovest Strategic Value Advisor's report that compares the environmental performance of 26 United States electric utilities. Innovest is an internationally recognized independent investment research firm specializing in environmental finance and investment opportunities.

In June 2007, FPL's Green (Vehicle) Fleet Program was named the winner of the 2007 Council for Sustainable Florida Large Business Best Practice Award for FPL's commitment to reducing fuel consumption in utilities' vehicle fleets. FPL received the award from the Council for Sustainable Florida, which honors businesses, organizations, and individuals whose work demonstrates that a healthy environment and healthy economy are mutually supportive. Since 1990, the Council has been committed to promoting and recognizing best sustainability practices in Florida.

For the third time, FPL Group was one of only four corporations in the North America Electric Power sector named in the "Climate Leadership Index," an honor roll of global corporations addressing the challenges of climate change.

In 2006, FPL and the Palm Beach County-based Arthur R. Marshall Foundation joined as "partners for the environment." FPL's support included a $25,000 donation to the non-profit organization for educational and restoration programs, including the planting of native Florida wetland trees. In 2007, FPL volunteers returned to help take care of the growing saplings.

FPL has also been the recipient of earlier environmental awards and recognition. In 2001, FPL was awarded Edison Electric Institute's National Land Management Award for its stewardship of 25,000 acres surrounding its Turkey Point Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. FPL received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" in 2001 for its emission-reducing "repowering" projects at its Fort Myers and Sanford Plants. FPL won the Council for Sustainable Florida's award in 2002 for its sea turtle conservation and education programs at its St. Lucie Plant. Finally, FPL has been recognized by numerous federal and state agencies for its innovative endangered species protection programs which include such species as manatees, crocodiles, and sea turtles.

As mentioned above, FPL Group has taken a leadership role to address climate change and the call for action for a national climate change policy. The decision to step into the forefront of this issue goes hand-in-hand with FPL Group's longtime commitment to managing operations with sensitivity to the environment.

FPL is taking action now in Florida to address climate change with a number of actions. According to the U.S. Department of Energy (DOE) data, FPL is one of the nation's leaders among electric utilities for its energy efficiency/conservation and load management achievement. FPL's nationally recognized leadership in the implementation of demand side management (DSM) within its system has avoided the need to build the equivalent of more than 12 medium-sized power plants as discussed in Chapters I and III of this document. Also discussed in Chapter III are FPL's plans for adding a significant amount of renewable energy resources. FPL is the nation's leader in power plant "repowerings" and "conversions," significantly increasing the efficiency of a number of its existing power plants while reducing FPL system emissions. Currently, two of FPL's older power plants are slated for conversion to state-of-the-art CC natural gas plants. In addition, FPL's future generation plans include nuclear uprates and two new nuclear units that are projected to significantly reduce air emissions in Florida.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Commitment in 1992 to clearly define its position. This statement reflects how FPL incorporates environmental values into all aspects of its activities and serves as a framework for new environmental initiatives throughout the company. FPL's Environmental Statement is:

> It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:
>
> - Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
> - Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
> - Encourage the wise use of energy to minimize the impact on the environment.
> - Communicate effectively on environmental issues.

- Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, a dedicated environmental corporate governance program, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident and/or emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with corporate policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and FPL policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2008 environmental outreach activities are noted in Table IV.E.1.

Table IV.E.1: 2008 FPL Environmental Outreach Activities

Activity	# of Participants
Visitors to FPL's Energy Encounter at St. Lucie	20,000
Visitors to Manatee Park	150,000
Number of visits to FPL's Environmental Website	358,000
Number of pieces of Environmental literature distributed	>80,000

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified eight Preferred Sites and four Potential Sites for future generation additions. Preferred Sites are those locations where FPL has conducted significant reviews and has either taken action, or is planning to take action, to site new generation capacity. Potential Sites are those sites that have attributes that support the siting of generation and are under consideration as a location for future generation. Some of these sites are currently in use as existing generation sites and some are not. The identification of a Potential Site does not indicate that FPL has made a definitive decision to pursue generation (or generation expansion in the case of an existing generation site) at that location, nor does this designation indicate that the size or technology of a generator has been determined. The Preferred Sites and Potential Sites are discussed in separate sections below.

As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites and other Greenfield sites.

IV.F.1 Preferred Sites

FPL identifies eight Preferred Sites in this Site Plan: the West County Energy Center (WCEC) adjacent to the existing Corbett FPL substation, the existing St. Lucie plant site, the existing Turkey Point plant site, the existing Cape Canaveral plant site, the existing Riviera plant site, and three locations for new solar power generation: DeSoto County, Brevard County, and the existing Martin plant site.

The West County Energy Center site is the location for three CC capacity additions FPL will make in 2009 through 2011. The St. Lucie site is the location for nuclear capacity uprates that FPL will make in 2011 and 2012. The St. Lucie site is also the location for a proposed wind generation addition. The Turkey Point site is the location for nuclear capacity uprates that FPL will make in 2011 and 2012 and is the site for two new nuclear units, Turkey Point Units 6 & 7, that are projected to be added in 2018 and 2020, respectively. The existing Cape Canaveral and Riviera plant sites are being proposed for conversion of the two existing steam generating units at each site into one state-of-the-art CC unit at each site in 2013 and 2014, respectively. The three solar projects (DeSoto County, Brevard County, and Martin County) are being proposed for operation in 2009, 2010, and 2010, respectively.

The eight Preferred Sites are discussed below.

Preferred Site # 1: West County Energy Center , Palm Beach County

FPL has identified the property adjacent to the existing Corbett Substation property in unincorporated western Palm Beach County as a Preferred Site for the addition of new generating capacity. The site was selected for the addition of three new CC natural gas power plants with ultra-low sulfur light fuel oil (distillate) as a backup fuel. WCEC Units 1 & 2 have been approved by both the FPSC and the Governor and Cabinet acting as the Siting Board. WCEC Unit 3 has been approved by both the FPSC and the Secretary of the FDEP in lieu of the Governor and Cabinet. The units are scheduled to come in-service in 2009 through 2011, respectively. All three CC units will be identical in regard to technology and capacity.

The existing site is accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections. The facility will use natural gas as the primary fuel and state-of-the-art combustion controls.

a. U.S. Geological Survey (USGS) Map

A USGS map of the West County Energy Center (WCEC) plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the WCEC generating facilities at the site is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

The site was inactive until February 2007 when construction of WCEC Units 1 & 2 was initiated. The site was previously dedicated to industrial (mining) and agricultural use. The site had been excavated, back-filled, and totally re-graded to an elevation of approximately 10 feet above the surrounding land surface. Prior to initiation of power plant construction, no structures were present on the site and vegetation was virtually non-existent. Structures are now being built on the site for work associated with WCEC Units 1 & 2. Construction of WCEC Unit 3 is scheduled to begin in 2009.

e. **General Environment Features On and In the Site Vicinity**

1. **Natural Environment**

The plant site had been significantly altered by the construction and operation of a limestone mine where vegetation had been cleared and removed. The surrounding land use is predominantly sugar cane, agriculture, and limestone mining. FPL's existing Corbett substation is located north of the site. The Arthur R. Marshall Loxahatchee National Wildlife Refuge is located to the south of the site.

2. **Listed Species**

Construction and operation of new units at the site is not expected to affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the prior mining activities. Common wading birds can be observed on areas adjacent to, and occasionally within, the property. The property is adjacent to areas that have been identified as potential habitat for wood stork.

3. **Natural Resources of Regional Significance Status**

The construction and operation of a gas-fired CC generating facility at this location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands including the Arthur R. Marshall Loxahatchee National Wildlife Refuge. Construction will not result in any onsite wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design of each of the three units is comprised of the following: new 1,219 MW (Summer capacity) unit with each unit consisting of three new combustion turbines (CT) and three new heat recovery steam generators (HRSG) and a new steam turbine. Natural gas delivered via pipeline is the primary fuel type for this facility with ultra-low sulfur light fuel oil (distillate) serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the project site is "Rural Residential" according to the Palm Beach County Future Land Use Map. Designations for the area under the Palm Beach County Unified Land Development Code classified the project site and surrounding area as Special Agricultural District. The site has been granted conditional use for electrical power facilities under a General Industrial zoning district.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues.

i. **Water Resources**

In regard to WCEC Units 1 & 2, water from the Floridan Aquifer and surface water from the L10/L12 canal (when available) will be used for cooling, service, and process water. Potable water will be purchased from the Palm Beach County water municipality.

In regard to WCEC Unit 3, the primary water source for the project will be reclaimed (reuse) water that will come from Palm Beach County Water Utilities Department. FPL will obtain the necessary approvals to also supply WCEC Units 1 & 2 using reclaimed water once WCEC Unit 3 is operational. Reclaimed water will be used for cooling, service, and process water. Backup water sources include utilizing the Floridan Aquifer allocation permitted for WCEC Units 1 & 2, potable water from Palm Beach County, and the L10/L12 canal when made available by the South Florida

Water Management District (SFWMD). Potable water will be purchased from the Palm Beach County water municipality.

j. Geological Features of Site and Adjacent Areas

The site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, clay, and phosphate grains. The deepest formation in Palm Beach County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Oldsmar formation. The published information on the sediments comprising the formations below the Avon Park Limestone is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach counties.

Testing during construction of Exploratory Well 2 (EW-2) demonstrated the presence of a highly permeable zone (Boulder Zone) below a depth of 2,790 feet below pad level (bpl) overlain by a thick confining interval from approximately 2,000 to 2,790 feet bpl. The base of the Underground Source of Drinking Water (USDW) was identified between the depths of 1,932 and 1,959 feet bpl through interpretation of packer tests, water quality data, and geophysical logs. Injection testing has confirmed that the hydrogeology of the EW-2 site is favorable for disposal of fluids via a deep injection well system.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for industrial processing for all 3 units is approximately 675 gallons per minute (gpm) for uses such as process water and service water. Approximately 22.5 million gallons per day (mgd) of cooling water for the three generating units would be cycled through the cooling towers. Water quantities needed for other uses such as potable water are estimated to be approximately 35,000 gallons per day (gpd) for the entire WCEC site.

l. Water Supply Sources by Type

WCEC Units 1 & 2 will use available surface or ground water as the source of cooling water for the cooling towers. The cooling towers will also act as a heat sink for the facility auxiliary cooling system. Such needs for cooling and process water will comply with the existing SFWMD regulations for consumptive water use.

WCEC Unit 3 will use reclaimed water as the primary source of cooling water for the cooling tower. The cooling tower will also act as a heat sink for the facility auxiliary cooling system. Such needs for cooling and process water will comply with the existing SFWMD regulations for consumptive water use. In addition, reclaimed water used at WCEC must meet all relevant requirements of Chapter 62-610, F.A.C., Part III, for use in cooling towers.

It is anticipated that once WCEC Unit 3 is operational, reclaimed water will also become the primary cooling water source for WCEC Units 1 & 2.

m. Water Conservation Strategies Under Consideration

The use of reclaimed water is a water conservation strategy because it is a beneficial use of wastewater. Impacts on the surficial aquifer would be minimized and used only for potable water, if necessary. Water from the Floridan Aquifer or the L10/L12 canal will be used for cooling purposes as a backup water source and cooling towers will be utilized. In addition, captured stormwater may be reused in the cooling tower whenever feasible. Stormwater captured in the stormwater ponds will also recharge the surficial aquifer.

n. Water Discharges and Pollution Control

Heat will be dissipated in the cooling towers. Blowdown water from the cooling towers, along with other wastestreams, will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. In addition, captured stormwater may be reused in the cooling towers, whenever feasible. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is serviced by a new natural gas transmission pipeline that is capable of providing a sufficient quantity of gas to the entire site. Ultra-low sulfur light fuel oil (distillate) would be received by truck and stored in above-ground storage tanks to serve as backup fuel for the WCEC generating units.

p. Air Emissions and Control Systems

The use of natural gas and ultra-low sulfur light fuel oil (distillate) and combustion controls will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminants. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil (distillate) as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the WCEC generating units will incorporate features that will make them among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by construction at the site is expected to be below current noise levels for the residents nearest the site. Noise from the operation of the new units will be within allowable levels.

r. Status of Applications

In regard to WCEC Units 1 & 2, a Site Certification Application (SCA) for the construction and operation of the West County Energy Center project under the Florida Electrical Power Plant Siting Act was filed in April 2005 and received Site Certification by the Governor and Cabinet, acting as the Siting Board, in December 2006. The Florida Department of Environmental Protection (FDEP) issued an Underground Injection Control (UIC) Exploratory Well permit in January 2006 and another Exploratory Well Permit in December 2006. FDEP issued the Final UIC permit in May 2008. FDEP issued a Prevention of Significant Deterioration (PSD) air permit in January 2007. After acquiring these permits and authorizations, FPL initiated construction in February 2007 and anticipates an in-service date for WCEC Unit 1 of mid-2009 and Unit 2 by end of 2009.

In regard to WCEC Unit 3, an SCA was filed in December 2007 and received Site Certification by the Secretary of the FDEP, in lieu of the Governor and Cabinet, in November 2008. A Prevention of Significant Deterioration (PSD) air permit was filed in December 2007. The permit was issued by FDEP in July 2008. FPL proposes to initiate construction in 2009 and anticipates an in-service date of mid-2011. WCEC Unit 3 will utilize the UIC system permitted for the entire site.

Preferred Site # 2: St. Lucie Plant, St. Lucie County

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The plant site is bordered by the Atlantic Ocean to the east and the Indian River Lagoon to the west. Located on the site are two nuclear-powered generating units, St. Lucie Units 1 & 2, which have been in operation since 1976 and 1983, respectively. The St. Lucie site has been selected as a Preferred Site for the addition of two types of new generating capacity.

The first type of generating capacity addition is an increase in the capacity of the two existing nuclear generating units that is used to serve FPL's customers of approximately 103 MW for St. Lucie Unit 1 and 88 MW for St. Lucie Unit 2. This difference is due to FPL's 100% ownership share of St. Lucie 1 and its 85% ownership share of St. Lucie Unit 2. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing Turkey Point nuclear units, was approved by the FPSC in January 2008. The capacity uprates at St. Lucie for the two nuclear units sited there are projected to be in-service in late 2011 and 2012.

The second type of generating capacity addition is the proposed installation of FPL wind generation turbines at the plant site. In 2007, FPL began the St. Lucie County land use approval process, and soon after applied for the necessary federal and state permitting. However, a decision by the state and federal agencies on the St. Lucie Wind project's permitting won't be finalized until the local land use approval process is completed. The in-service date will depend on the approval and permitting process. Six wind turbines are being proposed that, in total, would have a maximum output of approximately 13.8 MW.

a. U.S. Geological Survey (USGS) Map

A USGS map of the FPL St. Lucie Nuclear site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the proposed generating facilities at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

St. Lucie Units 1 & 2 are pressurized water reactors, each having two steam generators. The prominent structures, enclosed facilities, and equipment associated with St. Lucie Units 1 & 2 include the containment building, the turbine generator building, the auxiliary building, and the fuel handling building.

Prominent features beyond the power block area include the intake and discharge canals, switchyard, spent-fuel storage facilities, technical and administrative support facilities, and public education facilities (the Energy Encounter and the College of Turtle Knowledge). Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay, and Indian River Lagoon.

In regard to the nuclear capacity uprates, the only changes will be modifications to the existing power generation facilities within the power block area, modifications to the switchyard facilities, and modifications to the transmission lines from St. Lucie to Midway substation. None of the other existing facilities at the plant will change as a result of the uprates. No changes to the nuclear power generation facilities are projected as a result of the proposed wind turbine additions.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The St. Lucie Plant includes the reactor buildings, turbine buildings, access/security building, auxiliary building, maintenance facilities, and miscellaneous warehouses and other buildings associated with the operation of Units 1 & 2. The site includes adjacent undeveloped mangrove areas. As a result of the approved capacity uprates, the site characteristics will not change.

The proposed wind turbines are also located on the FPL-owned site. Impacts to the site characteristics are projected to be minimal from the proposed wind turbines.

2. Listed Species

Some listed species known to occur in the area of the plant location are atlantic sturgeon, smalltooth sawfish, loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas)*, leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtle (*Eretmochelys imbriccata*), gopher tortoise (*Gopherus polyphemus*), kemp's ridley sea turtle (*Lepidochelys kempi*), wood stork (*Mycteria americana*), black skimmer (*Rynchops niger*), and least tern (*Sterna antillarum*).

In regard to the nuclear capacity uprates, neither the development work, nor the continued operation of the two nuclear units after the uprate work has been completed, are expected to adversely affect any rare, endangered, or threatened species. No changes in wildlife populations at the adjacent undeveloped areas are anticipated, including listed species. Noise and lighting impacts will not change and it is expected that wildlife will continue to use the undeveloped areas within the St. Lucie Plant boundary.

In regard to the wind turbines, some changes to the adjacent undeveloped areas are anticipated. Noise and lighting impacts will not change and the wind turbines are not anticipated to deter the continued use by wildlife of the undeveloped areas within the St. Lucie Plant boundary or any adjacent areas.

3. **Natural Resources of Regional Significance Status**

Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay, and Indian River Lagoon.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. It is a once-through system. The effects of the discharge of cooling water via these discharge structures were evaluated and mixing zones were established to allow compliance with thermal water quality standards as a part of the Plant's NPDES (Permit No. FL0002208). These mixing zones include the volume of water beyond the discharge structures, at the edge of which the water temperature is no greater than 17°F above the ambient temperature of the intake water.

In regard to the nuclear capacity uprates, the once-through system will continue to be used for the nuclear units. In regard to the wind turbines, no water will be required.

g. **Local Government Future Land Use Designations**

St. Lucie Units 1 & 2 are located in unincorporated St. Lucie County, Florida. The County has adopted a comprehensive plan, which is updated on a periodic basis. The County Comprehensive Plan incorporates a map that depicts the future land use categories of all property falling within the unincorporated portions of the County. The St. Lucie Plant has a Future Land Use category of Transportation/Utilities (T/U) according to the St. Lucie County Future Land Use Map. The T/U category is described in the St. Lucie County Comprehensive Plan Future Land Use Element Future Land Use.

In regard to the wind turbines, FPL has submitted an application to St. Lucie County to rezone the land that would serve as the footprint of the turbines to the T/U category.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity. The site has been selected as a Preferred Site for the wind turbines because of the available wind resource at that location.

i. Water Resources

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. The once-through system flow will not change as a result of the nuclear uprates. No water will be required to operate the wind turbines. Due to the existing nature of the St. Lucie Plant, surrounding surface waters will not be adversely affected by either of the generation capacity additions. Stormwater will be handled by the existing facilities and no new areas will be impacted. Wetlands, groundwater, and nearby surface waters will not be impacted.

j. Geological Features of Site and Adjacent Areas

Beneath the land surface, there is a peat layer 4 to 6 feet thick. Below this layer is the Anastasia Formation, a sedimentary rock formation composed of clay lenses, sandy limestone, and silty fine to medium sand with fragmented shells. This highly permeable stratum extends 35 to 90 feet below mean sea level (msl). Underlying this stratum there is a semi-permeable zone, The Hawthorn Formation, consisting of slightly clayey and very fine silt which extends 600 feet below msl.

The original surficial deposits at the St. Lucie Plant were excavated to a depth of 60 feet and backfilled with Category I or II fill. The fill is underlain by the Anastasia formation, a sequence of partially cemented sand and sandy limestone, which extend to an average depth of about 145 feet. The Anastasia is underlain to an depth of about 600 to 700 feet by the partially cemented and indurated sands, clays, and sandy limestones of The Hawthorn Formation. Underlying these surface strata are about 13,000 feet of Jurassic through Tertiary Formations, primarily carbonate rocks. These formations have a relatively gentle slope to the southeast.

k. Projected Water Quantities for Various Uses

In regard to the nuclear capacity uprates, no change is expected in the quantity or characteristics of industrial wastewaters generated by the facility. Therefore, no change in that compliance achievement status is expected. The capacity uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The St. Lucie Plant does not directly withdraw groundwater under its current operations and it will not withdraw groundwater after the capacity uprates work is completed. The use of water supplied by the City of Fort Pierce, which does withdraw groundwater, will remain unchanged and there will be no changes to the groundwater discharges. There will be no quality, quantity, or hydrological changes, either by withdrawal or discharge to a drinking water source. Therefore, there will be no impacts on drinking water.

The wind turbines will not require water for operations and will not cause any changes in the hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow.

l. **Water Supply Sources by Type**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. General plant service water, fire protection water, process water, and potable water are obtained from City of Fort Pierce. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns.

The existing St. Lucie Plant water use is projected to be unchanged as a result of the nuclear capacity uprates. The wind turbines will not require water for operations.

m. **Water Conservation Strategies Under Consideration**

The existing water resources will not change as a result of the nuclear capacity uprates. The wind turbines will not require water for operations.

n. **Water Discharges and Pollution Control**

St. Lucie Units 1 & 2 use once-through cooling water from the Atlantic Ocean to remove heat from the main (turbine) condensers via the Circulating Water System (CWS), and to remove heat from other auxiliary equipment via the Auxiliary Equipment Cooling Water System (AECWS). The great majority of this cooling water is used for the CWS.

Under emergency conditions, water can be withdrawn from Big Mud Creek via the Emergency Intake Canal through two 54-inch pipe assemblies in the barrier wall that separates the Creek from the Canal. FPL does not use this intake during normal operations, but does test this system quarterly.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

The wind turbines will not require water for operations. Consequently, there will be no water discharge as a result of these turbines.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

St. Lucie Units 1 & 2 are licensed for uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core. Each reactor core includes 217 fuel assemblies.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 47,000 megawatt-days per metric ton uranium. In regard to the nuclear capacity uprates, more nuclear fuel will be used due to the increased capacity of each generating unit. No changes in the fuel-handling facilities are required. The addition of the wind turbines will have no fuel-related impact; i.e., no impacts from fuel delivery, storage, waste, or pollution control. Used fuel assemblies are stored in the onsite Nuclear Regulatory Commission (NRC)-approved spent fuel storage facilities. Following completion of the uprates, approximately 11 percent more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel-handling facilities are required.

Diesel fuel is used in a number of emergency generators that include four main plant generators, two building generators, and various general purpose diesel engines. The main plant emergency generators will not be changed as a result of either of the two types of generation capacity additions. These emergency generators are for standby use only and are tested to assure reliability and for maintenance. Diesel fuel is delivered to the St. Lucie Plant by truck as needed, and stored in tanks with secondary containment.

p. Air Emissions and Control Systems

The St. Lucie Plant is classified as a minor source of air pollution, since FDEP has issued a Federally Enforceable State Operating Permit (FESOP) to keep emissions less than 100 tons per year for any air pollutant regulated under the Clean Air Act.

The applicable units at the St. Lucie Plant in regard to air emissions consist of eight large main plant diesel engines, two smaller diesel engines, and various general-purpose diesel engines. The air emissions from these engines are limited by the use of 0.05-percent sulfur diesel fuel and good combustion practices. Best Available Control Technology (BACT) is not applicable to these existing emission units.

Nitrogen oxide (NO_x) emissions from the operation of the diesel engines comprise the limiting pollutant for these diesel units at the St Lucie Plant. The FDEP FESOP limits NO_x emissions to 99.4 tons, which includes fuel use limits on the large main plant emergency diesel engines of 97,000 gallons in any 12-month consecutive period and the smaller building and general purpose diesel engines of 190,000 gallons in any 12-month consecutive period. Also, the Plant may choose to combine the diesel units' fuel-tracking, which then limits the NO_x totals for a 12-month consecutive period to a maximum of 80 tons. There will be no change in the operation or emissions of the diesel engines resulting from either the nuclear capacity uprates or the wind turbines.

In addition, neither of these types of generation capacity additions will result in an increase of carbon dioxide (CO_2) or other greenhouse gas emissions. In fact, both of these increases in generation capacity are projected to result in decreased FPL system-wide emissions of CO_2.

q. <u>Noise Emissions and Control Systems</u>

A field survey and impact assessment of noise expected to be caused by construction activities at the site was conducted in regard to both types of generation capacity additions. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site during construction or operation of either generating capacity additions.

r. <u>Status of Applications</u>

In regard to the nuclear capacity uprates, a Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in December 2007 and a final order issued in September 2008. The FPSC voted to approve the need for the St. Lucie (and Turkey Point) nuclear capacity uprates and the final order approving the need for these capacity additions was issued in January 2008. In regard to the wind turbines, a Site Certification Application is not required. Individual permit applications were submitted for an Environmental Resource Permit (ERP) and the Army Corps of Engineers Permits in May 2008 and the Coastal Construction Control Line in July 2008. In September of 2007, FPL submitted an application to St. Lucie County for a

Conditional Use, Rezoning, and Height Amendment. The local approvals process is ongoing.

Preferred Site # 3a: Turkey Point Plant, Miami-Dade County – Nuclear Capacity Uprates

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear units (Units 3 & 4), two natural gas/oil conventional boiler units (Units 1 & 2), one CC natural gas unit (Unit 5), 9 small diesel generators, the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the Everglades Mitigation Bank (EMB).

Turkey Point Units 3 & 4 have been in operation since 1972 and 1973, respectively. The Turkey Point site has been selected as a Preferred Site for the increase in the capacity of its two existing nuclear generating units by approximately 103 MW each. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new or expanded facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing St. Lucie nuclear units, was approved by the FPSC in January 2008. The capacity uprates at Turkey Point are projected to be in-service in 2012.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the Turkey Point plant site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the Turkey Point Units 3 and 4 generating facility at the site is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The five existing power generation units and support facilities occupy approximately 150 acres of the 11,000-acre Turkey Point Plant. Support facilities include service buildings, an administration building, fuel oil tanks, water treatment facilities, circulating water intake and outfall structures, wastewater treatment basins, and a system substation. The cooling canal system occupies approximately 5,900 acres. The two 400-megawatt (MW) (nominal) fossil fuel-fired steam electric generation units at the Turkey Point Plant have been in service since 1967 (Unit 1) and 1968 (Unit 2). These units currently burn residual fuel oil and/or natural gas with a maximum equivalent sulfur content of 1 percent. The two 700-MW (nominal) nuclear units have been in service since 1972 (Unit 3) and 1973 (Unit 4). Turkey Point Units 3 and 4 are pressurized water reactor (PWR) units. Turkey Point Unit 5 is a nominal 1,150-MW CC unit that began operation in 2007. Significant features in the vicinity of the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The prominent structures and enclosed facilities and equipment associated with Units 3 & 4 include: the containment building, which contains the nuclear steam supply system, including the reactor, steam generators, reactor coolant pumps, and related equipment; the turbine generator building, where the turbine generator and associated main condensers are located; the auxiliary building, which contains waste management facilities, engineered safety components, and other facilities; and the fuel handling building, where the spent fuel storage pool and storage facilities for new fuel are located. Prominent features beyond the power block area include the intake system, cooling canal system, switchyard, spent fuel storage facilities, and technical and administrative support facilities.

2. Listed Species

The construction during the uprating of the units, and operation of the units after the capacity uprating is completed, are not expected to adversely affect any rare, endangered, or threatened species. Listed species known to occur at the site and in the nearby Biscayne National Park that could potentially utilize the site include the peregrine falcon *(Falco peregrinus)*, wood stork *(Mycteria americana)*, American crocodile *(Crocodylus acutus)*, mangrove rivulus *(Rivulus marmoratus)*, roseate spoonbill (*Ajaja ajaja*), limpkin (*Aramus guarauna*), little blue heron (*Egretta caerulea*), snowy egret (*Egretta thula*), American oystercatcher (*Haematopus palliates*), least tern (*Sterna antillarum*), the white ibis (*Eudocimus albus*), and bald eagle (*Haliaeetus leucocephalus*). No bald eagle nests are known to exist in the vicinity of the site. The federally listed, threatened American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American crocodile and is attributed with survival improvement and the downlisting of the American Crocodile from endangered to threatened.

3. <u>Natural Resources of Regional Significance Status</u>

Significant features in the vicinity on the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park. Biscayne National Park contains 180,000 acres, approximately 95% of which is open water interspersed with more than 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant and is adjacent to the Miami-Dade County Homestead Bayfront Park which contains a marina and day-use recreational facilities.

4. <u>Other Significant Features</u>

FPL is not aware of any other significant features of the site.

f. <u>Design Features and Mitigation Options</u>

Turkey Point Units 3 & 4 uses cooling water from a closed-cycle cooling canal system to remove heat from the main (turbine) condensers, and to remove heat from other auxiliary equipment. The existing cooling canals will accommodate the increase in heat load that is associated with the increased capacity from the uprates. The maximum predicted increase in water temperature entering the cooling canal system from the units resulting from the uprates is predicted to be about 2.5°F, from 106.1°F to 108.6°F. The associated maximum increase in water temperature returning to the units is about 0.9°F, from 91.9°F to 92.8°F.

g. **Local Government future Land Use Designations**

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity.

i. **Water Resources**

Unique to Turkey Point plant site is the self-contained cooling canal system that supplies water to condense steam used by the plant's turbine generators. The canal system consists of 36 interconnected canals. The cooling canals occupy an area approximately 2 miles wide by 5 miles long (5,900 acres), approximately four feet deep. The system performs the same function as a giant radiator. The water is circulated through the canals in a two-day journey, ending at the plant's intake pumps.

j. **Geological Features of Site and Adjacent Areas**

The Turkey Point Plant lies upon the Floridian Plateau, a partly-submerged peninsula of the continental shelf. The peninsula is underlain by approximately 4,000 to 15,000 feet of sedimentary rocks consisting of limestone and associated formations that range in age from Paleozoic to Recent. Little is known about the basement complex of Paleozoic igneous and metamorphic rocks due to their great depth.

Generally in Miami-Dade County, the surficial aquifer (Biscayne Aquifer) consists of a wedge-shaped system of porous clastic and carbonate sedimentary materials, primarily limestone and sand deposits of the Miocene to late Quaternary age. The Biscayne Aquifer is thickest along the eastern coast and varies in thickness from 80 to 200 feet thick. The surficial aquifer is typically composed of Pamlico Sand, Miami Limestone (Oolite), the Fort Thompson and Anastasia Formations (lateral equivalents), Caloosahatchee Marl, and the Tamiami formation. The lower confining layers below the surficial aquifer range in thickness from 350 to 600 feet and are composed of the Hawthorn Group. Beneath the Hawthorn Group, the Floridan Aquifer System ranges from 2,800 to 3,400 feet thick and consists of Suwannee Limestone, Avon Park Limestone, and the Oldsmar Formations.

k. Projected Water Quantities for Various Uses

The addition of nuclear generating capacity as a result of the uprates will not cause any changes in the quantity or characteristics of industrial wastewaters generated by the facility; therefore, no change in that compliance achievement status is expected. The uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The Turkey Point Plant does not directly withdraw groundwater under its current operations and it will not do so after the capacity uprates. Locally, groundwater is present beneath the Site in the surficial or Biscayne Aquifer and in deeper aquifer zones that are part of the Floridan Aquifer System. There will be no effects on those deeper aquifer zones from the capacity uprates.

l. Water Supply Sources and Type

The source of cooling water for Turkey Point Units 3 & 4 is the cooling canal system. There will be no increase in the amount of water withdrawn as a result of the capacity uprates. General plant service water, fire protection water, process water, and potable water are obtained from Miami-Dade County. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns. The water use for the facility will not change as a result of the capacity uprates.

m. Water Conservation Strategies

The existing water resources will not change as a result of the uprates.

n. Water Discharges and Pollution Control

Heated water discharges are dissipated using the existing closed cooling water system and the cooling canal system.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Turkey Point Units 3 & 4 utilize uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core. Used fuel assemblies are stored in the onsite NRC-approved spent fuel storage facilities.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 45,000 megawatt-days per metric ton of uranium. Following completion of the uprates, more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel handling facilities are required. Following completion of the uprates, approximately 11 percent more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel-handling facilities are required.

Diesel fuel is used in a number of emergency generators that include four main emergency generators, five smaller emergency generators and various general purpose diesel engines. The emergency generators will not be changed as a result of the capacity uprates. These emergency generators are for stand-by use only and only operated for testing purposes to assure reliability and for maintenance. Diesel fuel for the emergency generators is delivered to the Turkey Point Plant by truck as needed, and stored in tanks with secondary containment.

p. <u>Air Emissions and Control Systems</u>

The normal operation of Turkey Point Units 3 & 4 does not create fossil fuel-related air emissions. However, there are 9 emergency generators associated with Units 3 & 4. Four of these 9 emergency generators are main plant emergency generators which are rated at 2.5 MW each. The remaining 5 are smaller emergency generators which are associated with the security system. In addition, various general purpose diesels are used as needed for Units 3 & 4.

Turkey Point Plant Units 3 & 4's associated emergency generators and diesel engines, together with Units 1, 2, and 5, are classified as a major source of air pollution. FDEP has issued a separate Title V Air Operating Permit for the Turkey Point Nuclear Plant (Permit Number 0250003-004-AV). There are no operating limits for the emergency generators or diesel engines. Emergency diesel generators are limited to ultra-low sulfur distillate (0.0015% sulfur). NOx emissions are regulated under Reasonably Available Control Technology (RACT) requirements in Rule 62-296.570(4)(b)7 F.A.C., which limit NO_x emissions to 4.75 lb/MMBtu. The use of 0.05

percent sulfur diesel fuel and good combustion practices serve to keep NO_x emissions under this limit.

q. Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by activities associated with the uprates was conducted. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site.

r. Status of Applications

A Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in January 2008 and a final order was issued in October 2008. The FPSC voted to approve the need for the Turkey Point (and St. Lucie) uprates and the final order approving the need for this additional nuclear capacity was issued in January 2008.

Preferred Site # 3b: Turkey Point Plant, Miami-Dade County – Unit 6 (& 7)

The Turkey Point Plant property has been selected for two new nuclear generating units (Units 6 & 7) scheduled to come into service in 2018 and 2020, respectively. (Although the projected in-service year of Unit 7, 2020, is outside of the ten-year reporting period addressed in the 2009 Site Plan, FPL has included information regarding this unit.) The Turkey Point Plant property is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 8 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the operating nuclear units located there. The land surrounding the site is owned by FPL providing a buffer zone. The site is comprised of two existing nuclear units (Units 3 and 4), two natural gas/oil conventional boiler units (Units 1 & 2), one CC natural gas unit (Unit 5), 9 small diesel generators, the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the FPL Everglades Mitigation Bank (EMB).

a. U.S. Geological Survey (USGS) Map

A map of the Turkey Point Units 6 & 7 site is found at the end of this chapter.

b. Proposed Facilities Layout

The Turkey Point Units 6 & 7 site layout is still under development. Information regarding the layout will be presented in future FPL Site Plans as this information becomes available.

c. Map of Site and Adjacent Areas

An overview map of the Turkey Point Units 6 & 7 site and adjacent areas is found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

Approximately 150 acres of the 11,000 acre Turkey Point Plant Property are used for the existing generation and support facilities and a closed cooling pond. The cooling canal system occupies approximately 5,900 acres. The remaining acreage primarily consists of forested uplands, disturbed uplands, and wetland habitat. Approximately 300 acres within the cooling canal system will be used for Turkey Point Units 6 & 7 site. Significant features in the vicinity include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The location for Turkey Point Units 6 & 7 operating facility is entirely within the cooling canal system that supports the operating plants. This is a previously impacted environment. Some of the associated facilities (e.g. roads, pipelines, etc.) will extend outside of the cooling canal system. These associated facilities are still under development and the potential natural environment in those areas are still under review.

2. Listed Species

Listed species known to occur at the site and in the nearby Biscayne National Park include the peregrine falcon *(Falco peregrinus)*, wood stork *(Mycteria americana)*, American crocodile *(Crocodylus acutus)*, mangrove rivulus *(Rivulus marmoratus)*, roseate spoonbill (*Ajaja ajaja)*, limpkin *(Aramus guarauna)*, little blue heron *(Egretta caerulea)*, snowy egret *(Egretta thula)*, American oystercatcher *(Haematopus palliates)*, least tern *(Sterna antillarum)*, the white ibis *(Eudocimus albus)*, and bald eagle *(Haliaeetus leucocephalus)*. No bald eagle nests are known to exist in the vicinity of the site. The federally listed, threatened American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals that lie south of the project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American Crocodile and is attributed with survival improvement and the downlisting of the American Crocodile from endangered to threatened.

3. **Natural Resources of Regional Significance Status**

Significant features in the vicinity of the Turkey Point plant property include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park. Biscayne National Park contains 180,000 acres, approximately 95% of which is open water interspersed with over 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant and is adjacent to the Miami-Dade County Homestead Bayfront Park that contains a marina and day use recreational facilities.

4. **Other Significant Features**

FPL is not aware of any other significant features of the Turkey Point Units 6 & 7 sites.

f. **Design Features and Mitigation Options**

Design features and mitigation options for Turkey Point Units 6 & 7 are still under development. Information regarding these design features and mitigation options will be presented in future FPL Site Plans as this information becomes available.

g. **Local Government future Land Use Designations**

FPL received zoning approval for Turkey Point Units 6 & 7 from Miami-Dade County in December 2007. FPL continues to work with Miami-Dade County on land use designations as project features develop.

h. **Site Selection Criteria Process**

FPL conducted an extensive site selection analysis leading to the selection of the Turkey Point site as the site that, on balance, provided the most favorable location for developing new nuclear generation to serve FPL's customers. The Site Selection

Study employed the principles of the Electric Power Research Institute (EPRI) siting guidelines and is modeled upon applicable NRC site suitability and National Environmental Policy Act (NEPA) criteria regarding the consideration of alternative sites. The study convened a group of industry and FPL subject matter experts to develop and assign weighting factors to a broad range of site selection criteria. Twenty-three candidate sites were then ranked using the siting criteria. This review allowed the list of candidates to be reduced until the best site emerged. Key factors contributing to the selection of Turkey Point include the existing transmission and transportation infrastructure to support new generation, the large size and seclusion of the site while being relatively close to the load center, and the long-standing record of safe and secure operation of nuclear generation at the site since the early 1970s.

i. Water Resources

Unique to the Turkey Point plant property is the self-contained cooling canal system that provides closed cooling to Turkey Point Units 1-4. The canal system consists of 36 interconnected canals. The cooling canals occupy an area approximately 2 miles wide by 5 miles long (5,900 acres), approximately four feet deep. The system performs the same function as a giant radiator. The water is circulated through the canals in a two-day journey, ending at the plant's intake pumps. These water resources will not be used by Turkey Point Units 6 & 7. The two new nuclear units currently propose to use reclaimed municipal wastewater as a primary cooling water source.

j. Geological Features of Site and Adjacent Areas

The Turkey Point Plant property lies upon the Floridian Plateau, a partly-submerged peninsula of the continental shelf. The peninsula is underlain by approximately 4,000 to 15,000 feet of sedimentary rocks consisting of limestone and associated formations that range in age from Paleozoic to Recent. Little is known about the basement complex of Paleozoic igneous and metamorphic rocks due to their great depth.

Generally in Miami-Dade County, the surficial aquifer (Biscayne Aquifer) consists of a wedge-shaped system of porous clastic and carbonate sedimentary materials, primarily limestone and sand deposits of the Miocene to late Quaternary age. The Biscayne Aquifer is thickest along the eastern coast and varies in thickness from 80 to 200 feet thick. The surficial aquifer is typically composed of Pamlico Sand, Miami Limestone (Oolite), the Fort Thompson and Anastasia Formations (lateral equivalents), Caloosahatchee Marl, and the Tamiami formation. The lower confining layers below the surficial aquifer range in thickness from 350 to 600 feet and are composed of the Hawthorn Group. Beneath the Hawthorn Group, the Floridan Aquifer System ranges from 2,800 to 3,400 feet thick and consists of Suwannee Limestone, Avon Park Limestone, and the Oldsmar Formations.

k. Projected Water Quantities for Various Uses

The quantities of cooling water and potable water needed for Turkey Point Units 6 & 7 are still under development. At this time it is estimated that up to 90 million gallons per day (mgd) of reclaimed wastewater will be needed for make-up cooling water. In the event that reclaimed water is not available it is estimated at this time that up to 130 mgd of saltwater will be needed for make-up cooling water.

l. Water Supply Sources and Type

Potential water supply sources for Turkey Point Units 6 & 7 are still being analyzed. FPL has conducted an extensive water alternatives analysis to identify the universe of water alternatives for the project. Based on this analysis, FPL is investigating further the use of reclaimed water as the primary source of make-up cooling water for Turkey Points Units 6 & 7. Information regarding the water supply sources and type will be presented in future FPL Site Plans as this information becomes available.

m. Water Conservation Strategies

Turkey Point Units 6 & 7 is expected to use cooling towers, which significantly reduce the cooling water requirements. Reclaimed wastewater is being developed as the primary make-up cooling source. Using reclaimed wastewater allows for a secondary beneficial use of regional municipal wastewater that would otherwise be discharged to the ocean or injected into deep wells by the Miami Dade County Water and Sewer Department. Other water conservation strategies are still in development for Turkey Point Units 6 & 7. Information regarding these water conservation strategies will be presented in future FPL Site Plans as this information becomes available.

n. Water Discharges and Pollution Control

The water discharge strategy for the Turkey Point Units 6 & 7 is still under development, but use of an Underground Injection Control (UIC) system is being considered as the primary waste discharge alternative. Information regarding water discharge will be presented in future FPL Site Plans as this information becomes available.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The delivery, storage, waste disposal and pollution control requirements for Turkey Point Units 6 & 7 are all currently under development. Information regarding these matters will be presented in future FPL Site Plans as this information becomes available.

p. Air Emissions and Control Systems

The normal operation of Turkey Point Units 6 & 7 will not create fossil fuel-related air emissions. In addition, emissions from emergency generators associated with Units 6 & 7 are expected to be insignificant. The air emissions and control system are still under development. Information regarding the air emissions and control system will be presented in future FPL Site Plans as this information becomes available.

q. Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by activities associated with the Turkey Point Units 6 & 7 are under evaluation. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the Turkey Point Units 6 & 7.

r. Status of Applications

FPL is currently collecting data and developing permit applications. FPL expects to submit applicable local, state, and federal applications for the project during mid-to-late-2009. The Turkey Point Units 6 & 7 Unusual Use approval was issued by Miami Dade County in December 2007.

Preferred Site # 4: Cape Canaveral Plant, Brevard County

This site is located on the existing FPL Cape Canaveral Plant property in unincorporated Brevard County. The site is bound to the east by the Indian River Lagoon and on the west by a four lane highway (US. 1). The city of Port St. Johns is located less than a mile away. A rail line is located near the plant.

The existing 788 MW (summer) of generating capacity at FPL's Cape Canaveral site occupies a portion of the 43 acres that are wholly owned by FPL. The generating capacity is made up of steam units (Units 1 and 2).

The Cape Canaveral Plant site has been listed as a Potential Site in previous FPL Site Plans for both CC and simple cycle generation options. FPL is proposing to convert the existing Cape Canaveral Plant, to be renamed the Cape Canaveral Next Generation Clean Energy Center (CCEC), into a modern, highly efficient, lower-emission next-generation clean energy center using the latest CC technology. The existing two (2) steam units will first be dismantled and removed from the site and will be replaced by a single new CC unit.

a. Geological Survey (USGS) Map

A USGS map of the Cape Canaveral plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the CCEC generating facilities at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing land uses on the site are primarily dedicated to electrical generation; i.e., FPL's existing Cape Canaveral power plant Units 1 & 2. The existing land uses that are adjacent to the site consist of single- and multi-family residences to the south and southwest, commercial property to the northwest, utility systems to the west, and a private medical/office facility to the north.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The natural environment surrounding the site includes the Indian River Lagoon to the east and upland scrub, pine and hardwoods to the north and south. Vegetation with the approximately 45-acre offsite construction laydown and parking area (located west of U.S. Highway 1) consists of open land, upland scrub, pine, hardwoods along with exotic plant species.

2. **Listed Species**

No adverse impacts to federally or state-listed terrestrial plants and animals are expected in association with construction at the Site, due to the existing developed nature of the Site and lack of suitable onsite habitat for listed species. Federal- or state-listed terrestrial plants and animals inhabiting the offsite construction laydown and parking area are limited to the state-listed gopher tortoise and the state- and federally-listed scrub jay. The warm water discharges from the plant attract manatees, an endangered species. FPL is working closely with state and federal wildlife agencies to ensure protection of the manatees during the conversion process and upon operation of the modernized plant.

3. **Natural Resources of Regional Significance Status**

The construction and operation of a natural gas-fired CC generating facility at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design option is to convert the existing steam generating units (Units 1 & 2) with one new 1,219 MW (approximate) CC unit consisting of three new combustion turbines (CT), three new heat recovery steam generators (HRSG), and a new steam turbine. The new CC unit would be in-service in mid-2013. Natural gas delivered via pipeline is the primary fuel type for this unit with ultra-low sulfur light oil serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the site is "Public Utilities" and the area has been rezoned to GML-U.. Designations for the surrounding area are primarily "Community Commercial" and "Residential". The Indian River Lagoon is to the east of the site.

h. **Site Selection Criteria Process**

The Cape Canaveral plant has been selected as a preferred site for a site conversion due to consideration of various factors including system load and economics.

Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. However, there are environmental benefits of converting the existing steam units including a significant reduction in system air emissions and improved aesthetics at the site.

i. <u>Water Resources</u>

Condenser cooling for the steam cycle portion of the converted plant and auxiliary cooling will come from the existing cooling water intake system. Process, potable, and irrigation water for the converted plant will come from the existing City of Cocoa's potable water supply.

j. <u>Geological Features of Site and Adjacent Areas</u>

FPL's Cape Canaveral Plant is located on the Atlantic Coastal Ridge and is at an approximate elevation of 12 feet above mean sea level (msl). The land consists primarily of fine to medium sand that parallels the coast. There is a lack of shell as it was deposited during a time of transgression. The base of the sedimentary rocks is made up of a thick, primarily carbonate sequence deposited during the Jurassic age through the Pleistocene age. Starting in the Miocene age and continuing through the Holocene age, siliciclastic sedimentation became more predominant. The basement rocks in this area consist of low-grade metamorphic and igneous intrusives, which occur several thousand feet below land surface and are Precambrian, Paleozoic, and Mesozoic in age.

k. <u>Projected Water Quantities for Various Uses</u>

The estimated quantity of water required for processing is approximately 0.281 million gallons per day (mgd) for uses such as process water and service water. Approximately 619 million gallons per day (mgd) of cooling water would be cycled through the once-through cooling water system. Potable water demand is expected to average .001 mgd.

l. <u>Water Supply Sources by Type</u>

The converted plant will continue to use the Indian River Lagoon water as the source of once-through cooling water. Such needs for cooling water will comply with the existing St. John's River Water Management District (SJRWMD) Consumptive Use Permit (CUP). Process, potable, and irrigation water for the converted plant will come from the existing City of Cocoa's potable water supply.

m. **Water Conservation Strategies Under Consideration**

No additional water sources will be required as a result of the conversion project.

n. **Water Discharges and Pollution Control**

The converted site will utilize portions of the existing once-through cooling water systems for heat dissipation. The heat recovery steam generator blowdown will be mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's once-through cooling water system. Stormwater runoff will be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. **Fuel Delivery, Storage, Waste Disposal, and Pollution Control**

Natural gas for the converted unit will be transported to the site via a pipeline. New on-site gas compressors may be installed to raise the gas pressure of the existing pipeline for the converted unit. Ultra-low sulfur light fuel oil would be received by truck or barge from Port Canaveral and stored in an existing above-ground storage tank.

p. **Air Emissions and Control Systems**

The use of natural gas and ultra-low sulfur light fuel oil and combustion controls will minimize air emissions from the unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the converted CCEC plant will incorporate features that will make it among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise from the operation of the new unit will be within allowable levels.

r. Status of Applications

A Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in December 2008 and is currently under review. The FPSC voted to approve the need for the conversion project and the final order was issued in September 2008.

Preferred Site # 5: Riviera Plant, Palm Beach County

This site is located on the existing FPL Riviera Plant property primarily within Riviera Beach, Palm Beach County (with a small portion of the Site in West Palm Beach). The site is bound to the east by the Lake Worth Lagoon (Intracoastal Waterway) and on the west by a four lane highway (US. 1). The site has barge access via the Port of Palm Beach. A rail line is located near the plant.

The current site generating capacity is made up of two (2) operational 300 MW (approximate) steam generating units (Units 3 & 4). Units 1 & 2 have been retired and dismantled and are no longer on the plant site.

The Riviera Plant site has been listed as a Potential Site in previous FPL Site Plans for both CC and simple cycle generation options. FPL is proposing to convert the existing Riviera Plant, to be renamed the Riviera Beach Next Generation Clean Energy Center (RBEC), into a modern, highly efficient, lower-emission next-generation clean energy center using the latest CC technology. The existing two steam units will first be removed from the site and will be replaced by a single new CC unit.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Riviera site is found at the end of this chapter.

b.

c. Proposed Facilities Layout

A general layout of the RBEC generating facilities is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing Riviera Plant currently consists of two 300 MW (approximate) units with conventional dual-fuel fired steam boilers and steam turbine units. The plant site includes minimal vegetation and a landscape buffer area south of the power plant. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the site is comprised of facilities related to electric power generation for the existing Riviera Plant. The site is located on the Intracoastal waterway which provides warm water refugia for manatees during cold winter days.

2. Listed Species

No adverse impacts to federally or state-listed terrestrial plants and animals are expected in association with construction at the Site, due to the existing developed nature of the Site and lack of suitable onsite habitat for listed species. The warm water discharges from the plant attract manatees, an endangered species. FPL is working closely with state and federal wildlife agencies to ensure protection of the manatees during the conversion process and upon operation of the new plant.

3. Natural Resources of Regional Significance Status

The construction and operation of a natural gas-fired CC generating facility at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to convert the existing units (Units 3 & 4) to one new 1,207 MW (approximate) unit consisting of three new combustion turbines (CT), three new heat recovery steam generators (HRSG), and a new steam turbine. The new CC unit would be in service in mid-2014. Natural gas delivered via pipeline is the primary fuel type for the unit with ultra-low sulfur light oil serving as a backup fuel.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is "Utility". The Port of Palm Beach is to the north of the site. Designation to the west of the site is "Commercial". To the south of the site is "Residential" and is in the City of West Palm Beach.

h. Site Selection Criteria Process

The Riviera plant has been selected as a Preferred Site to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. However, there are environmental benefits of converting the existing steam units including a significant reduction in system air emissions and improved aesthetics at the site.

i. Water Resources

Water from the Lake Worth Lagoon (Intracoastal waterway) is currently used for once-through cooling water. The converted plant will utilize portions of the existing once through cooling water intake and discharge structures. Water for cooling pump seals and irrigation will come from three onsite surficial aquifer wells. Process and potable water for the converted plant will come from the existing City of Riviera Beach potable water supply.

j. Geological Features of Site and Adjacent Areas

FPL's Riviera Plant site is underlain by the surficial aquifer system. The Surficial aquifer system in eastern Palm Beach County is primarily composed of sand, sandstone, shell, silt, calcareous clay (marl), and limestone deposited during the Pleistocene and Pliocene Epochs. The sediments forming the aquifer system are the Pamlico Sand, Fort Thompson Formation (Pleistocene) and the Caloosahatchee Marl (Pleistocene and Pliocene). Permeable sediments in the upper part of the Tamiami Formation (Pliocene) are also part of the aquifer system. The sediments in the eastern portion of the county are appreciably more permeable than in the west due to better sorting and less silt and clay content.

The surficial aquifer is underlain by at least 600 feet the Hawthorn formation (confining unit). The Floridan Aquifer System underlies the Hawthorn formation.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for processing is approximately 0.232 mgd for uses such as process water and service water. Approximately 600 million gallons per day (mgd) of cooling water would be cycled through the once-through cooling water system. Potable water demand is expected to average .001 mgd.

l. Water Supply Sources by Type

The converted plant will continue to use the Lake Worth Lagoon water as the source of once-through cooling water. Water for cooling pump seals and irrigation will come from on-site surficial aquifer wells currently permitted by SFWMD. Process and potable water for the converted plant will come from the existing City of Riviera Beach's potable water supply.

m. Water Conservation Strategies Under Consideration

No additional water sources will be required as a result of the conversion project.

n. Water Discharges and Pollution Control

The converted plant will utilize portions of the existing once-through cooling water system for heat dissipation. The heat recovery steam generator blowdown will be mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's once-through cooling water system prior to discharge. Stormwater runoff will be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for the converted unit will be transported to the site via a pipeline. New on-site gas compressors may be installed to raise the gas pressure of the existing pipeline to the appropriate level for the converted unit. Ultra-low sulfur light fuel oil would be received by truck, pipeline or barge from the Port of Palm Beach and stored in a new above-ground storage tank.

p. Air Emissions and Control Systems

The use of natural gas and ultra-low sulfur light fuel oil and combustion controls will minimize air emissions from the unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of RBEC will incorporate features that will make it among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site.

r. Status of Applications

A Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in February 2009 and is currently under review. The FPSC voted to approve the need for the conversion project and the final order was issued in September 2008.

Preferred Site # 6: DeSoto Next Generation Solar Energy Center, DeSoto County

The DeSoto site is located approximately 0.3 miles east of US 17 and immediately north of Bobay Road in Arcadia, Florida. The site is located in Section 27, Township 36 South, Range 25 East. FPL owns an approximately 13,000 acre parcel in DeSoto County. FPL has designated approximately 1,523 acres for development of a photovoltaic (PV) facility. The land surrounding the site is owned by FPL and acts as a buffer zone.

The DeSoto site has been selected as a Preferred Site for the addition of a 25 MW PV generation facility. The DeSoto Next Generation Solar Energy Center is expected to be in operation by the end of 2009.

a. U.S. Geological Survey (USGS) Map

A USGS map of the DeSoto Next Generation Solar Energy Center plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the DeSoto Next Generation Solar Energy Center generating facility at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

This property is owned by FPL. The site was inactive until November 2008 when construction of the DeSoto Next Generation Solar Energy Center was initiated. The site was previously dedicated to agricultural use. An approximately 400 acre portion of the site has been cleared and re-graded to accommodate the PV project. Prior to initiation of construction, no structures were present on the site and the majority of the vegetation was sod. Structures are now being built on the site for work associated with DeSoto Next Generation Solar Energy Center.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The site has been altered by construction. The surrounding land use is predominantly agriculture. FPL was able to design the PV facility to avoid impacts to most of the natural wetlands.

2. Listed Species

Prior to construction and operation of the new facility one listed species was observed at the site, the gopher tortoise. Gopher tortoises are classified as threatened by the Florida Fish and Wildlife Conservation Commission, but are not listed federally by the U.S. Fish and Wildlife Service. Gopher tortoise burrows were observed in the palmetto prairie and woodland pasture. Other listed species are known to utilize gopher tortoise burrows (commensal species), including the Eastern indigo snake (*Drymarchon corais couperi*; federally and state threatened), gopher frog (*Rana capito*; state species of special concern), and Florida mouse (*Podomys floridanus*; state species of special concern). A permit was obtained to relocate the gopher tortoises and any commensal species. Construction and operation at the site is not expected to affect any rare, endangered, or threatened species.

3. **Natural Resources of Regional Significance Status**

The construction and operation of the PV generating facility at this location is not expected to have any adverse impacts on parks or recreation areas. Construction will result in minimal wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

FPL conducted an archeological and historical survey and no artifacts were discovered. FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design consists of 25 MW of PV technology. This site is also suitable for possible expansion of PV beyond the 25 MW facility. No mitigating options are deemed necessary at the site.

g. **Local Government future Land Use Designations**

The local government future land use designation for the 25 MW project site is Agriculture on the DeSoto County Future Land Use Map.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site for the installation of a PV technology due to consideration of various factors including prior FPL ownership of the land and its suitability for a PV facility of this magnitude.

i. **Water Resource**

No water will be required for use at the solar facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Should this minimal water be required, it will be trucked to the site as needed.

j. **Geological Features of the Site and Adjacent Areas**

The dominant soil types within the site are Myakka, Smyrna, Immokalee, EauGallie, Basinger, and Valkaria fine sands. Basinger fine sand, depressional; and Anclote muckyfine sand, depressional. All the dominant soil types are considered poorly to very poorly drained.

k. Projected Water Quantities for Various Uses

The projected water use for the solar facility is expected to be minimal with water being used occasionally only to clean the PV panels.

l. Water Supply Sources and Type

The PV facility will use a small amount of water to occasionally clean the PV panels. This water will come from groundwater. FPL will obtain a consumptive use permit once the facility goes into operation.

m. Water Conservation Strategies

This PV facility does not require water use for daily operations.

n. Water Discharges and Pollution Control

There will not be any water discharges or pollution as a result of this facility operation.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The facility will use the sun for fuel. Therefore there will not be any fuel delivery, storage, waste, or pollution at the site.

p. Air Emissions and Control Systems

No air emissions will be emitted from this facility.

q. Noise Emissions and Control Systems

Noise expected during construction is expected to be below noise level allowed by DeSoto County. No noise will be emitted from this facility during operation.

r. Status of Applications

FPL obtained an Environmental Resource Permit (ERP) from the FDEP in October 2008. FPL received an Army Corps of Engineers permit in October 2008.

Preferred Site #7: Space Coast Next Generation Solar Energy Center, Brevard County

The Space Coast site (Site) is located at Section 13, Township 23 South, and Range 36 East, North of North Courtenay Parkway. FPL is leasing approximately 60 acres from Kennedy Space Center in Brevard County. This Space Coast site has been selected as a Preferred Site for the addition of a 10 MW PV generation facility. The Space Coast Next Generation Solar Energy Center is expected to be in operation by the end of 2010.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Space Coast Next Generation Solar Energy Center plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the Space Coast Next Generation Solar Energy Center generating facility is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The site is inactive. The Site was previously dedicated to agricultural use as citrus groves. There are no structures on the site and the majority of the vegetation is citrus grove.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The surrounding land use is predominantly agriculture. FPL was able to design the PV facility to avoid most of the impacts to natural wetlands.

2. Listed Species

Wildlife resources at the Site were evaluated in February 2008 through pedestrian surveys. There were no listed species observed.

3. **Natural Resources of Regional Significance Status**

The construction and operation of a PV generating facility at this location is not expected to have any adverse impacts on parks or recreation areas. Construction will result in minimal wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design consists of 10 MW of PV technology. No mitigating options are deemed necessary at the site.

g. **Local Government future Land Use Designations**

Future land use designation for the site is Spaceport Management as designated by the Brevard County Future Land Use Map.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site for the installation of a PV technology due to consideration of various factors including its suitability for a PV facility of this magnitude and the cooperation of the Kennedy Space Center.

i. **Water Resource**

No water will be required at the PV facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficant rainfall. Any such water would be brought to the site by truck.

j. **Geological Features of the Site and Adjacent Areas**

The surface and near-surface deposits of east-central Florida range from surficial unconsolidated sands to well indurated limestones and dolomites at depth. In ascending order the four main geologic units present in east-central Florida are: (i) Eocene limestones; (ii) Lower and Middle Miocene compact silt and clays; (iii) Upper Miocene and Pliocene silty and clayey sands; and (iv) Pleistocene and Recent age sands with interbedded shell layers.

k. Projected Water Quantities for Various Uses

The projected water use for the PV facility is expected to be minimal with water being used occasionally only to clean the PV panels.

l. Water Supply Sources and Type

At this time, it is expected that natural rainfall will be sufficient to keep the solar panels clean. In the event that additional water is required, a small amount of water may be occasionally trucked in to clean the PV panels.

m. Water Conservation Strategies

FPL constructed this PV facility knowing it would not use water for operation and would only need a minimal amount for cleaning the PV panels.

n. Water Discharges and Pollution Control

There will not be any water discharges or pollution as a result of this facility

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The facility will use the sun for fuel. Therefore there will not be any fuel delivery, storage, waste, or pollution at this site.

p. Air Emissions and Control Systems

No air emissions will be emitted from this facility.

q. Noise Emissions and Control Systems

Noise expected during construction is expected to be below noise levels allowed by Brevard County. No noise will be emitted from this facility during operation.

r. Status of Applications

FPL applied for an Environmental Resource Permit (ERP) from the St. Johns Water Management District and a U.S. Army Corps of Engineers permit in July 2008.

Preferred Site #8: Martin Next Generation Solar Energy Center, Martin County

The Martin Next Generation Solar Energy Center (MSEC) will be located on the existing FPL Martin Plant site in unincorporated Martin County, Florida. The Martin Plant site is located in southwestern Martin County about 40 miles northwest of West Palm Beach and about 1.3 miles east of Lake Okeechobee (Figure 2.1-1). The Martin Plant site is bounded by State Road (SR) 710 and a CSX Railroad line (east and north), a Florida East Coast Railway line and SFWMD L-65 Canal (west), and the St. Lucie Waterway (south).The MSEC Project will be constructed in an approximately 600-acre area (Project Area) within FPL's existing 11,300-acre Martin Plant site. The land surrounding the site is owned by FPL and acts as a buffer zone.

The site has been selected as a Preferred Site for the addition of approximately 75 MW of solar thermal generation. The facility will produce steam that will replace steam that would otherwise have been produced by burning natural gas in one of the existing CC units at the site, Martin Unit 8. The Martin Next Generation Solar Energy Center is expected to be in operation by the end of 2010.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the Martin Next Generation Solar Energy Center plant site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the Martin Next Generation Solar Energy Center generating facility is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

Total site acreage for the existing Martin Plant site is approximately 11,300 acres, which represents land owned by FPL. The Martin Plant site consists of a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of embankment) and approximately 400 acres for existing Units 1 through 4, Unit 8, and associated facilities. Units 1 & 2 are nominal 800-MW steam electric generating units that use natural gas and low-sulfur residual oil. Units 3 & 4 are nominal 500-MW natural gas-fired CC units. Unit 8 is a natural gas fired 4-on-1 CC unit with a nominal capacity of 1,100 MW that began operation in 2005. Light oil is used as backup in Unit 8. The other onsite facilities include water and wastewater treatment facilities, residual and light fuel oil storage, switchyards and transmission lines, offices, warehouses, maintenance buildings, and other miscellaneous uses.

Adjacent areas include agricultural uses such as croplands, pastures, and groves account for much of the land use and cover within 5 miles of the Martin Plant site. Three types of wetlands, forested freshwater, non-forested freshwater, and mixed forested and forested freshwater also account for a great deal of nearby land use.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The portions of the Martin Plant site that will be affected by the construction of the MSEC are about 550 acres that will be utilized for solar arrays and construction facilities. The solar arrays will be located east of the existing Unit 8. Activities associated with construction will occupy about 100 acres. This will include construction laydown, parking, and trailers. These areas will be cleared of any vegetation. The area for the heat exchangers will be near Unit 8 and this area has been previously impacted by the construction of Units 3, 4, and 8.

2. Listed Species

Threatened and endangered species within the Project Area are limited to avian species and gopher tortoise. No listed species of plants were identified within the MSEC Project Area. Due to the presence of large areas of similar habitat both within the Northwest Mitigation Area and areas north of the existing transmission line ROW adjacent to the Project Area, and the highly mobile nature of protected avian species, no significant adverse impacts to federally or state listed animals are expected. Creation of wood stork foraging ponds and sandhill crane habitat within the Northwest Mitigation Area provides suitable habitat to offset the loss of shallow hydroperiod wetlands within the Project Area.

Gopher tortoises are classified as threatened by the FFWCC, but are not listed federally by the USFWS. Gopher tortoise burrows were observed in the palmetto prairie and woodland pasture. Other listed species are known to utilize gopher tortoise burrows (commensal species), including the Eastern indigo snake (*Drymarchon corais couperi*; federally and state threatened), gopher frog (*Rana capito*; state species of special concern), and Florida mouse (*Podomys floridanus*; state species of special concern). A permit was obtained to relocate the gopher tortoises and any commensal species. Construction and operation at the Site is not expected to affect any rare, endangered, or threatened species

3. **Natural Resources of Regional Significance Status**

The construction and operation of a solar thermal facility at this location is not expected to have any adverse impacts on parks or recreation areas. Construction will result in minimal wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

The Florida Department of State, Division of Historical Resources, has determined that no significant archaeological or historical sites are recorded or are likely to be present within the Project Area. As a result no construction impacts on historic properties listed or eligible for listing in the National Register of Historic Places, or otherwise of historical or archaeological value, are anticipated.

f. **Design Features and Mitigation Options**

The design consists of approximately 75 MW of solar thermal technology. FPL has already undertaken an extensive wetland mitigation program on a 1,130-acre parcel northwest of the existing Martin Plant generating units. That mitigation program was deemed successful by the SFWMD in 2001. All wetland impacts associated with the MSEC have been fully mitigated through this now-successful wetland and upland mitigation effort.

g. **Local Government future Land Use Designations**

The Martin Plant site that includes Units 1 & 2 was developed prior to the county's adoption of a future land use map. In 1982, at the time of the original land use plan map adoption, the portion of the Martin Plant site surrounding the existing units was designated Industrial. The Electric Utility Element of the Comprehensive Plan acknowledged FPL's plans to construct two coal gasification plants at the Martin Plant site and encouraged the facilities to be developed under the industrial planned unit development [PUD(i)] zoning designation. In September 1988, FPL requested a comprehensive plan land use amendment to industrial for the licensing of the Martin CG/CC Project Area and a rezoning of that area to PUD(i). In August 1989, the Martin County Board of County Commissioners (BOCC) approved the comprehensive plan amendment and the rezoning request. In June 2008, with the BOCC approval of the rezoning, a PUD Zoning Agreement was executed between Martin County and FPL in which development standards and special conditions were addressed. Most of the special conditions were addressed during earlier phases of developing the Martin Plant site. An amendment of the PUD Zoning Agreement was requested by FPL to allow renewable energy facilities to be located within the PUD area. Subsequent to the certification of the CG/CC Project, which includes the area of the MSEC, Martin County has amended its future land use element and map to designate 7,300 acres in the Martin Plant site as Public Utilities – Major Public Power Generation Facilities.

h. Site Selection Criteria Process

The site has been selected as a Preferred Site due to consideration of various factors including available land area and proximity to an existing generating unit (Martin Unit 8) to which the steam generated by the solar thermal facility could be fed.

i. Water Resource

There will be no water used at the solar thermal facility except the small amount needed to occasionally clean the solar mirrors. The additional water needed for mirror cleaning is already within the previously approved allocation of water for the Martin Plant site.

j. Geological Features of the Site and Adjacent Areas

Borings drilled in the area just east of the existing Unit 8 show that the predominant soil type is sand from the ground surface [approximately 30 feet above mean sea level (ft-msl)] to –70 ft-msl (negative number denotes feet below sea level). The sands vary in color from light to dark gray and brown. Clayey sand and sandy clay seams from a few inches to several feet in thickness are generally found at 10 ft-msl. A thin layer of greenish-gray sandy clay was found in the borings at approximately –25 ft-msl. The Pamlico and Anastasia Formations extend from the ground surface (20 to 30 ft-msl) to an average of –3 ft-msl. These strata consist of fine sands and silty sands with shell fragments. Thin beds of limestone and cemented sand occur sporadically at depths ranging from 2 to 4.5 ft-msl in localized areas; this zone may represent the boundary between the Pamlico and Anastasia Formations. In areas where the cemented sands and limestone are absent, it is not possible to differentiate the two formations.

The underlying Caloosahatchee Group extends to an average –80 ft-msl. This formation can be subdivided into two units, namely an upper limestone interbedded with sand and shell present to an average –12 ft-msl, and a lower unit of silty sand with shell fragments and shell beds to –80 ft-msl. The Tamiami Formation underlies the Caloosahatchee from –105 ft-msl to –150 ft-msl. This formation consists of silty sand varying with depth to clayey sand from –72 ft-msl. The color of the formation also varies from gray in the sands to predominantly green in the clayey zone.

The top of the Hawthorn Group occurs at approximately –105 ft-msl to –150 ft-msl. These elevations are based on the logs of test wells and exploratory borings drilled in the area. The Hawthorn, approximately 550 ft thick, consists predominantly of greenish clay with subordinate amounts of shell, limestone, silt, and sand. Major limestone zones generally occur near the base of the formation. Due to very low vertical permeability, the Hawthorn acts as a confining bed overlying the Floridan Aquifer.

k. Projected Water Quantities for Various Uses

Washing mirrors requires about 50 gallons per 120 mirrors (i.e., a 50 meter section). Based on the amount of mirrors for the MSEC, about 75,000 gallons per washing will be required. This amount of water is estimated to be no more than about 2 million gallons per year for cleaning mirrors.

l. Water Supply Sources and Type

The plant water use for MSEC can be accommodated by the current authorization for water in the Conditions of Certification (PA89-27L). The amount of water required by the MSEC is estimated to not exceed about 2 million gallons per year for cleaning mirrors, or an annual average of about 5 gallons per minute (gpm). The usage will be intermittent, with maximum usage of about 75,000 gallons every 1 or 2 weeks during periods without rain and depending upon the reflectivity of the mirrors. The source of water for the MSEC is the existing demineralized water system.

m. Water Conservation Strategies

FPL plans to construct this solar thermal facility knowing it will use very little water for operation.

n. Water Discharges and Pollution Control

There will not be any water discharges or pollution as a result of this facility.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The facility will use the sun for fuel. Therefore, there will not be any fuel delivery, storage, waste, or pollution at the site from the operation of the solar thermal facility.

p. Air Emissions and Control Systems

There will be no SO_2, NO_x, or CO_2 emissions from the solar thermal facility and its operation will result in reductions of FPL system emissions for all three types of emissions.

There will be minor amounts of volatile organic compounds (VOCs) released from the expansion tanks as a result of decomposition products of heat transfer fluids (HTF). Based on reported values from FPL Energy SEGS facilities in California, the VOC emissions from the MSEC will be about 0.8 tons per year (TPY). This amount would classify these emissions as insignificant activities and the amount is well below the threshold requiring permitting under FDEP rules in 62-210.300, F.A.C. A generic exemption is that emissions of any regulated pollutant be less than 5 TPY. The 5 TPY applies to the "potential-to-emit" for the emission unit, which would be 8,760 hours/year unless restricted as an enforceable permit condition in a permit. The exemption covers the requirement to obtain construction permits required pursuant to Rule 62-210.300(1), F.A.C.

q. Noise Emissions and Control Systems

Noise during construction is expected to be below noise level allowed by Martin County. There will not be any noise from the solar thermal facility during operation.

r. Status of Applications

FPL submitted an application for a Site Certification Modification for the Martin Next Generation Solar Energy Center to the FDEP in May 2008. FPL received the site certification modification approval in August 2008.

IV.F.2 Potential Sites for Generating Options

Four sites are currently identified as Potential Sites for near-term future generation additions to meet FPL's capacity and energy needs.[3]

[3] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites and other greenfield sites. Greenfield sites that FPL currently does not own, or for which FPL has not currently secured the necessary rights to, are not specifically identified as Potential Sites in order to protect the economic interests of FPL and its customers.

. These sites have been identified as Potential Sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these Potential Sites offer a range of considerations relative to engineering and/or costs associated with the construction and operation of feasible technologies. In addition, each Potential Site has different characteristics that will require further definition and attention. Solely for the purpose of estimating water requirements for each site, it was assumed that either one dual-fuel (natural gas and light oil) simple cycle combustion turbine (CT) or a natural gas-fired CC unit would be constructed at the Potential Sites unless otherwise noted. A simple cycle CT would require approximately 50 gallons per minute (gpm) for both process and cooling water (assuming air cooling). A CC unit would require approximately 150 gpm for service and process water and approximately 14 million gallons per day (mgd) for cooling water depending upon the water source and associated water quality. If an existing power plant site is ultimately selected for converting an existing unit(s), the water requirements discussed above for a CC unit would be approximately correct for the converted unit. If a renewable energy generating technology, such as photovoltaic or solar thermal, is ultimately selected for one of these sites, the water requirements would be less than those for CT or CC facilities.

Permits are presently considered to be obtainable for each of these sites. No significant environmental constraints are currently known for any of these sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time FPL considers each site to be equally viable.

Potential Site # 1: West Broward, Broward County

FPL has identified the Andytown Substation property in western unincorporated Broward County as a potential site for the addition of new generating capacity and FPL refers to this potential site as the West Broward site. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. U.S. Geological Survey (USGS) Map

A USGS map of the site has been included at the end of this chapter.

b. **Land Uses**

The land uses for the site were designated as agricultural use.

c. **Environmental Features**

Extensive low-quality wetlands are present on the site. Construction and operation of a new facility on this site would not be expected to adversely affect any rare, endangered, or threatened species.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Groundwater from the shallow aquifer or a local source of reclaimed (reuse) water has been identified as potential water sources. The Floridan Aquifer has also been identified as a potential cooling water source.

Potential Site # 2: Fort Myers Plant, Lee County

FPL's existing 460-acre Fort Myers property is located just east of Interstate 75 in Lee County and is adjacent to the Caloosahatchee River. The existing facilities on the site include one 1,440 MW (approximate) CC unit, 12 gas turbines, each with an approximate capacity of 54 MW, and two combustion turbines, each with an approximate capacity of 160 MW.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the Fort Myers plant site is found at the end of this chapter.

b. **Land Uses**

The land on the site is currently dedicated to industrial use with surrounding grassy and landscaped areas. Much of the site has been used in recent years for direct plant construction activities. The adjacent land uses include light commercial and retail to the east of the property, plus some residential areas located toward the west.

c. **Environmental Features**

Mixed scrub with some hardwoods can be found to the east and further south.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

The available water source is the Caloosahatchee River and the available groundwater source is the sandstone aquifer.

Potential Site # 3: Lauderdale Plant, Broward County

The Lauderdale site is located in Eastern Broward County approximately 5 miles inland from Dania Beach and less than 2 miles west of Ft. Lauderdale International Airport. The site is bounded on the south by Dania Cutoff Canal, on the east by S.W. 30th Avenue, and on the North by I-595.

The existing approximately 1,700 MW of generating capacity at FPL's Lauderdale site occupies a portion of the approximately 210 acres that are wholly owned by FPL. The generating capacity is made up of two CC units (Units 4 & 5), and 24 simple cycle gas turbine (GT) units.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. **Land Uses**

The existing power plant facilities are located on approximately 130 acres. The existing site has been in use since the 1920s and is adjacent to a county resource recovery project.

c. **Environmental Features**

To the north of the power plant is an area of mixed uplands with a scattering of small wetlands.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. Supply Sources

Existing groundwater or the municipal water supply are potential water sources.

Potential Site # 4: Manatee Plant, Manatee County

The site for the Project is the existing FPL Manatee Plant 9,500-acre site, located in unincorporated north-central Manatee County. The existing power generating facilities are located in all or portions of Sections 18 and 19 of Township 33S, Range 20-E. The plant site lies approximately 5 miles east of Parrish, Florida. It is approximately 5 miles east of U.S. 301 and 9.5 miles east of Interstate Highway 75 (I-75). The existing plant is approximately 2.5 miles south of the Hillsborough-Manatee County line; a portion of the north property boundary of the plant site abuts the county line. State Road 62 (SR 62) is about 0.7 mile south of the plant, with the plant entrance road going north from that highway. This site is a possibility for an FPL solar thermal facility.

a. U.S. Geological Survey (USGS) Map

A map of the site is found at the end of this chapter.

b. Land Uses

Existing Land use on the site is agricultural. FPL is attempting to rezone the property to PD-PI which will allow for electrical generation.

c. Environmental Features

There are no significant environmental features on the site.

d. Water Quantities

Minimal amounts of water would be required for a solar thermal facility.

e. Supply Sources

The existing water supply could be used for the water required to clean the mirrors for a solar thermal facility.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints: external limitations and internal limitations. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance that is available to the FPL system as well as the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new units that minimize adverse impacts to the flow of electricity within FPL's system. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations and by evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system. Both of these site- and system-related transmission costs are developed for each different unit/unit location option or groups of options. In addition, transfer limits for capacity and energy that can be imported into the Southeastern region of FPL's system are also developed for use in FPL's production costing analyses. (A further discussion of the Southeastern Florida region and the need to maintain a regional balance between generation and transmission contributions is found in Chapter III.)

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's planned transmission facilities to interconnect and integrate FPL's resource plans and those that must be certified under the Transmission Line Siting Act are presented in Chapter III.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.[4]

The load forecast that is presented in FPL's 2009 Site Plan was developed in January 2009. FPL has not performed sensitivity analyses on forecasts that differ from this recently developed load forecast.

[4] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its fuel price forecasts are discussed in Chapter III of this document. FPL's 2008 resource planning work utilized up to four different fuel cost forecasts (and four different environmental compliance cost forecasts). Detailed discussions of those fuel cost forecasts, and the results of utilizing them on the resource plans being analyzed in each filing, were presented to the FPSC in FPL's filings for Determination of Need for WCEC Unit 3 and the conversions of FPL's existing Cape Canaveral and Riviera plants. In addition, FPL used different fuel and environmental compliance cost forecasts in the 2008 nuclear cost recovery filings for the nuclear uprates of its existing nuclear units and for the new Turkey Point Units 6 & 7.

The resource plan presented in this Site Plan is largely the result of those prior analyses. For that reason, this resource plan, with the recently developed January 2009 load forecast, has not been further tested for different fuel cost forecasts.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item # 3, FPL used up to four fuel forecasts in the filings for Determination of Need, and/or cost recovery filings, for a variety of new units as described in the previous question. While these forecasts did not represent a constant cost differential between oil/gas and coal, a variety of fuel cost differentials were represented in these forecasts.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 in Chapter I, and Schedule 8 in Chapter III, present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options in its resource planning work. A summary of this information for the new capacity options FPL projects to add over the planning horizon is presented on the Schedule 9 forms in Chapter III.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

In its 2008 resource planning work, FPL used two sets of key financial assumptions. A 44.2% debt and 55.8% equity FPL capital structure was used throughout this work. In its early 2008 analyses, FPL used a 6.43% projected debt, an equity return of 11.75%, and after-tax discount rate of 8.4% for generation costs and 8.3% for all other costs. In its analyses later in 2008, FPL used 6.6% projected debt, an equity return of 11.75%, and after-tax discount rate of 8.35%. The change in the discount rate assumption is due partly as a result of the change in the cost of debt assumption and partly because FPL no longer assumes that the federal manufacturing tax credit would likely apply to new generating units built in the time frame discussed in this analysis. This latter assumption change also resulted in the same discount rate (8.35%) being applied to both generation and non-generation costs in the analyses presented in this filing.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). As discussed in response to Discussion Item # 2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective are identical when DSM levels are unchanged between competing plans. Therefore, in planning work in which DSM levels were unchanged, the equivalent cumulative present value of revenue requirements perspective was utilized.

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two system reliability criteria in its resource planning work that addresses generation, purchase, and DSM options. One of these is a minimum 20% Summer and Winter reserve margin. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability analysis work, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the Reliability Standards established by the North American Electric Reliability Council (NERC).The *NERC Reliability Standards* are available on the internet (http://www.nerc.com/.)

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Facility Rating Methodology* document that are also available on on the internet https://www.oatioasis.com/FPL /FPLdocs/Nov,2008 Revised FCR.docl.

Generally, FPL limits its transmission facilities to 100% of the applicable thermal rating. In regards to the normal and contingency voltage criteria for FPL stations, it is provided below:

	Normal/Contingency	
Voltage Level (kV)	**Vmin (p.u.)**	**Vmax (p.u.)**
69, 115, 138	0.95/0.95	1.05/1.07
230	0.95/0.95	1.06/1.07
500	0.95/0.95	1.07/1.09
Turkey Point (*)	1.01/1.01	1.06/1.06
St. Lucie (*)	1.00/1.00	1.06/1.06

(*) Voltage range criteria for FPL's Nuclear Power Plants

There may be isolated cases for which FPL may have determined it is acceptable to deviate from the general criteria stated above. There are several factors could influence this criteria, such as the overall potential customers that may be impacted, the probability of an outage actually occurring, or transmission system performance, as well as others.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM programs on demand and energy consumption is revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

The Executive Summary chapter provides a discussion of two system concerns that are typically addressed in FPL's resource planning work: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida. In addition, two other relatively recent items will also influence FPL's resource planning efforts. One of these items is the Executive Orders directive issued in 2007 by Governor Crist calling for reduction in greenhouse gas emissions and greater contribution from renewable energy sources. As previously discussed in both the Executive Summary chapter and Chapter III, FPL's resource planning has already taken positive steps in regard to both of these issues. The other item is the appropriate level of renewable energy contributions to a utility system in Florida, an issue that is currently being discussed by the Florida Legislature. The outcome of these discussions regarding Renewable Portfolio Standards (RPS) is not known at the time the 2009 Site Plan is being written. However, once the RPS outcome is known, FPL will take appropriate steps in its resource planning work. Those steps will likely be discussed next year in FPL's 2010 Site Plan.

In addition to these system concerns/issues, there are other strategic factors FPL typically considers when choosing between resource options. These include the following: (1) technology risk; (2) environmental risk, and (3) site feasibility. The consideration of these factors may include both economic and non-economic aspects.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts on the FPL system, including environmental compliance costs. Technologies regarded as more acceptable from an environmental perspective for a plan are those which minimize environmental impacts for the FPL system as a whole through highly efficient fuel use and state of the art controls.

Site feasibility assesses a wide range of economic, regulatory, and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed, elements of FPL's capacity additions include the construction of new generating capacity at the West County Energy Center (WCEC) site, WCEC Units 1, 2, and 3. These generation construction projects were selected after evaluating competing bids received in response to Requests for Proposals (RFP) issued by FPL. The FPSC subsequently approved FPL's decision to construct these new combined cycle (CC) units in Determination of Need dockets.

In regard to the Conversions projects at FPL's existing Cape Canaveral and Riviera plants, the conversion projects were also evaluated using the competing bids received in response to the RFP issued for WCEC Unit 3. In addition, bids from competing vendors were also evaluated for FPL's new solar thermal and PV projects.

The nuclear capacity additions, both the nuclear uprates and the new nuclear units, do not lend themselves to an RFP approach involving bids from third parties who would build new nuclear generation capacity. For these nuclear projects, FPL's procurement activities were conducted to ensure the best combination of quality and cost for the delivered products.

Construction capacity addition decisions for non-nuclear generation for years beyond those presented in this document are expected to be conducted in a manner consistent with the Commission's Bid Rule.

Identification of self-build options, beyond those units already approved by the FPSC and Governor and Siting Board or units for which FPL may be then seeking approval, in future FPL Site Plans will not be an indication that FPL has pre-judged any capacity solicitation it may conduct. The identification of future capacity units is required of FPL in its Site Plan filings and represents those alternatives that appear to be FPL's best, most cost-effective self-build options at the time. FPL reserves the right to refine its planning analyses and to identify other self-build options. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an RFP is issued for Supply options, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

(1) FPL identified the need for a new 230kV transmission line (by June 2009) that required certification under the Transmission Line Siting Act which was issued on April 2006. The new line, when completed, will connect FPL's St. Johns Substation to FPL's proposed Pringle Substation (also shown on Table III.E.1 in Chapter III). The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

(2) FPL has identified the need for a new 230kV transmission line (by December 2012) that required certification under the Transmission Line Siting Act which was issued on November 2008. The new line will connect FPL's Manatee Substation to FPL's proposed BobWhite Substation (also shown on Table III.E.1 in Chapter III). The construction of this line is necessary to serve existing and future customers in the Manatee and Sarasota areas in a reliable and effective manner.

RE: 2010-2019 Ten-Year Power Plant Site Plan

Dear Ms. Cole:

In accordance with Rule 25-22.071, F.A.C., please find enclosed for filing the original and twenty-five (25) copies of Florida Power & Light Company's 2010-2019 Ten-Year Power Plant Site Plan.

Please acknowledge your receipt of the above filing on the enclosed copy of this letter and return to the undersigned. Thank you for your assistance on this matter.

Sincerely,

Monica P. Caballero

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan. This plan should include an estimate of the utility's future electric power generating needs, a projection of how these estimated generating needs would be met, and disclosure of information pertaining to the utility's preferred and potential power plant sites. The information contained in this Site Plan is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (F.A.C.).

This Ten Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2009 and that were on-going in the first Quarter of 2010. The forecasted information presented in this plan addresses the 2010–2019 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten-year time horizon, and all of this information is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings, at the appropriate time.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, based on FPL's IRP work in 2009 and

early 2010.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as Preferred and Potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional information that is included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2010 Ten Year Power Plant Site Plan (Site Plan) presents FPL's current plans to augment and enhance its electric generation capability (owned or purchased) as part of its efforts to meet its projected incremental resource needs for the 2010 - 2019 time period. By design, the primary focus of this document is on supply side additions; i.e., electric generation capability and the sites for these additions. The supply side additions discussed in this document are resources projected to be needed after accounting for FPL's demand side management (DSM) contributions and the significant energy efficiency contributions from the latest, enhanced federal appliance and lighting efficiency standards. The projected impacts of the federal appliance and lighting efficiency standards are already reflected in FPL's load forecast presented in this document. The projected impacts of FPL's DSM contributions are addressed as projected reductions to the forecasted load.

The resource plan that is presented in FPL's 2010 Site Plan contains five key similarities to the resource plan presented in FPL's 2009 Site Plan. These similarities are especially applicable to the early years of the ten-year period. Conversely, there are three specific factors that are driving changes in FPL's resource plans. In addition, there are other factors that will continue to influence FPL's on-going resource planning work. A brief discussion of these similarities, changes, and other factors is provided below.

I. Similarities to the Resource Plan Presented in the 2009 Site Plan:

There are five key similarities in the current resource plan presented in this document compared to the resource plan presented in the 2009 Site Plan.

Similarity # 1: A third highly efficient combined cycle (CC) generating unit will be added to FPL's system in 2011.

One similarity to FPL's 2009 Site Plan is the addition of a third new highly efficient natural gas-fired CC generating unit at FPL's West County Energy Center (WCEC) site in 2011. FPL placed in-service two 1,219 MW (Summer) CC units at the WCEC site in 2009. These units are identified as WCEC Units 1 and 2. The WCEC Units 1 and 2 were approved by the Florida Public Service Commission (FPSC) in June 2006. Site Certification for these units under the Florida Electric Power Plant Siting Act was approved by the Governor and the Cabinet serving as the Siting Board in December 2006.

FPL is currently constructing the third new CC unit, WCEC Unit 3, at this site. This new CC unit is projected to go into commercial operation by mid-2011. The WCEC Unit 3 was approved by the FPSC in September 2008 and Site Certification for this unit was obtained in November 2008.

Similarity # 2: Additional renewable energy generation facilities will be installed on FPL's system in 2010.

In 2009, FPL completed construction, and began operation, of a 25 MW (nameplate rating) photovoltaic (PV) generation facility in DeSoto County. This was the first of three renewable energy installations that FPL committed to place in-service in the near-term. The other two renewable energy installations are a 10 MW (nameplate rating) PV facility in Brevard County and a 75 MW (nameplate rating) solar thermal facility in Martin County. The latter two projects are currently under construction and are scheduled to begin commercial operation in 2010.

Similarity # 3: Generating capacity at FPL's four existing nuclear generation units will increase in 2011 and 2012.

FPL will be adding approximately 400 MW of increased generating capacity from its existing Turkey Point and St. Lucie nuclear power plants. This increased capacity is scheduled to come in-service in the 2011 and 2012 time period. The need for these nuclear capacity "uprates" was approved by the FPSC in January 2008. The Final Order for the Site Certification was issued in September 2008 for the St. Lucie uprates and in October 2008 for the Turkey Point uprates.

Similarity # 4: A number of existing generating units will be placed temporarily on Inactive Reserve.

In 2009, FPL began to temporarily take a number of its existing generating units out of active service and place them on Inactive Reserve status until their continued operation is again needed. This practice will continue in 2010 and is currently projected to continue beyond 2010. The specific generating units that will be placed on Inactive Reserve status are discussed in Chapter III of this document.

Similarity # 5: This Site Plan continues to reflect the modernizations of FPL's existing Cape Canaveral and Riviera plant sites in 2013 and 2014.

FPL's 2009 Site Plan projected that the modernizations of FPL existing generating units at these two sites would occur in 2013 (Cape Canaveral) and 2014 (Riviera). FPL received need determination approval from the FPSC for both of these modernizations in 2008. FPL's 2010 Site Plan continues to show this same projection for resource planning purposes. As FPL has recently stated, FPL has suspended work on the modernization projects.

II. Factors That Are Driving Changes in FPL's Resource Plan:

There are three primary factors that are driving the changes in FPL's 2010 resource plan compared to the resource plan presented in FPL's 2009 Site Plan. These three factors, and their impacts on the resource plan, are summarized below and are addressed in more detail in Chapters II and III of this document.

Factor # 1: FPL's forecast of projected load is lower in the long-term than the 2009 load forecast.

The first factor that is driving changes in FPL's resource plan is FPL's new long-term load forecast that was prepared in February 2010. This new forecast projects lower growth in electrical demand and energy starting in 2015 compared to the 2009 load forecast that was shown in FPL's 2009 Site Plan. As a result of this new lower load forecast, FPL's current projected need for new resources in the 2010 – 2019 time period is significantly lower than had been projected in 2009.

Factor # 2: The FPSC has significantly increased goals for demand side management (DSM) resources that FPL must meet in the 2010 – 2019 time period.

The second factor that is driving changes in the current resource plan is the FPSC's decision in late 2009 to impose significantly higher goals for DSM resources for FPL to add in the 2010 – 2019 period. The amount of demand (MW) reduction from the new DSM goals far exceeds the 2009 projection of FPL's remaining resource needs through 2019.[1] Now, with FPL's lower 2010 load forecast, and the commensurately lower 2010 projection of resource needs, the amount by which the MW reductions from the new DSM goals exceeds FPL's resource needs is even larger. The new level of DSM goals has other significant implications for resource planning as indicated in the following section.

[1] It is the demand (MW) reduction aspect of DSM programs, not the energy (MWh) aspect that enables DSM to meet future resource needs; i.e., avoid the need for new generating units.

Factor # 3: Due to regulatory and commercial developments in 2009, the Turkey Point 6 & 7 project schedule is under review. For planning purposes, it is now assumed that the in-service dates will not be within the ten year reporting window of this Site Plan.

In recent Site Plans, FPL discussed its plans for pursuing additional nuclear capacity (beyond the above-mentioned nuclear uprates) through the addition of new nuclear units. These previous Site Plans reflected the addition of two new nuclear units at FPL's existing Turkey Point plant site, with these new units, Turkey Point Units 6 & 7, assumed to be placed in-service in 2018 and 2020, respectively. FPL received need determination approval from the FPSC for these units in early 2008. The assumed 2018 and 2020 in-service dates represented the earliest possible dates that FPL foresaw that these new units could become operational.

Beginning in late 2009, FPL began a review of project schedule, costs, and feasibility to determine the best path forward for the Turkey Point Units 6 & 7 project in light of the most current information. A revised plan based on that review will include the steps necessary to maintain progress in creating the option for new nuclear units while maintaining an appropriate control of risk exposure. Although the revised plan is not yet completed, it has become evident that, for planning purposes, it would not be appropriate to reflect the assumed in-service dates of Turkey Point Units 6 & 7 within the period covered by this Ten Year Site Plan.

III. Resulting Changes in FPL's Resource Plan Compared to the Resource Plan Presented in the 2009 Site Plan:

The factors discussed above contribute to two significant changes in FPL's resource plan presented in this document compared to the resource plan presented in FPL's 2009 Site Plan. The changes are summarized below.

Resulting Change # 1: FPL's 2010 Site Plan now projects no additional new generating units in the 2015 through 2019 time period.

FPL's lower February 2010 load forecast significantly reduces FPL's projected resource needs. And, as previously mentioned, the FPSC-imposed new goals for DSM, especially the new MW goals, already greatly exceeded the resource needs that FPL had previously projected, even using the higher load forecast that FPL utilized in 2009. The combination of these two factors results in FPL having no need for additional resources through the 2019 reporting period addressed in this Site Plan, beyond the previously mentioned WCEC 3 unit, the modernizations of the Cape Canaveral and Riviera sites, and the nuclear uprates. All of these capacity additions are currently projected to be completed by 2014.

Therefore, as shown by Table ES-1 that is presented at the end of this Executive Summary, FPL projects no new FPL generation unit additions from 2015 through 2019.

Resulting Change # 2: For planning purposes, the assumed in-service dates for the new Turkey Point Units 6 & 7 have moved beyond the 2010 – 2019 reporting frame of this Site Plan document.

As stated above, FPL's ongoing review of the Turkey Point Units 6 & 7 project indicates that, for planning purposes, it is no longer appropriate to reflect assumed in-service dates for the Turkey Point Units 6 & 7 within the 2010 – 2019 reporting time frame of this Site Plan. This is a result of slower than anticipated progress in a number of critical project areas. As a result, FPL's 2010 Site Plan does not include either of the new nuclear units as part of its resource plan in 2010 – 2019.

FPL recognizes that the addition of new nuclear units will result in significant system fuel savings, system emission savings, (including CO_2), and gains in system fuel diversity. For these reasons, FPL is continuing to pursue the licenses that will be necessary to construct new nuclear units at Turkey Point. At the time this document is being prepared, FPL is evaluating what the revised in-service dates for Turkey Point Units 6 & 7 should be for planning purposes. FPL will address those revised in-service dates for planning purposes in its May 3, 2010 nuclear cost recovery filing to the FPSC.

IV. Additional Factors Influencing FPL's Resource Planning Work:

In addition to the factors described above, other items will also influence FPL's resource planning work. Among these other items are two that FPL typically refers to as on-going system concerns that FPL has considered in its resource planning work for a number of years. These two on-going system concerns are: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida.

A third factor that will influence FPL's on-going resource planning efforts is the Executive Order directive issued in 2007 by Governor Crist, calling for reductions in greenhouse gas emissions and for increased contribution from renewable energy sources.

A fourth factor that could affect FPL's resource planning is the possibility of the establishment of a Florida standard for renewable energy or clean energy. A Renewable Portfolio Standard (RPS) proposal was prepared by the FPSC, and then sent to the Florida Legislature for consideration, with a possible change to a Clean Portfolio Standard (CPS), during the 2009 legislative session. However, no RPS or CPS legislation was enacted during the 2009 legislative session. RPS or CPS legislation, or other legislative initiatives regarding renewable or clean energy contributions, may occur in the future. If such legislation is enacted during 2010 or in later years, FPL will then determine what steps need to be taken to address the legislation. Such steps would then be discussed in FPL's Site Plan in the year following the enactment of such legislation.

Table ES-1 presents a current projection of the changes in the generating resources portion of FPL's resource plan based on the factors and changes discussed above. As such, this table does not specifically identify the impacts of the new DSM Goals, but these impacts are reflected in the reserve margin values presented in the table. The table also presents the impacts of the temporary placement of specific existing generating units on Inactive Reserve and the beginning of the return to active service of these generating units in the latter portion of the ten-year planning period.

Table ES-1: Projected Capacity Changes and Reserve Margins for FPL

Projected Capacity Changes and Reserve Margins for FPL (1)

Year	Projected Capacity Changes	Net Capacity Changes (MW) Winter (2)	Summer (3)	Reserve Margin (%) Winter	Summer
2010	Martin Next Generation Solar Energy Center (Solar Thermal) (7)	—	—

2019	Inactive Reserve of Existing Units - online (8)	394	387	28.4%	19.8%
	TOTALS =	84	39		

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are forecasted values for January of the year shown. FPL's actual 2010 Winter peak was significantly higher than forecasted.
(3) Summer values are forecasted values for August of the year shown.
(4) These are firm capacity and energy contracts with QF, utilities, and other entities. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown. All additions assumed to start in June are included in the Summer reserve margin calculation starting in that year and in the Winter reserve margin calculation starting with the next year.
(6) Because of the intermittent nature of the photovoltaics (PV) resource, FPL is currently assigning no firm capacity benefit to these generating additions. FPL will reassess this once actual operating data from the PV facilities at these locations is available. This location-specific information is needed in order to gauge consistent output during the peak hours which are accounted for in FPL's reserve margin calculations.
(7) The Martin solar thermal facility is designed to provide steam for FPL's existing Martin Unit 8 combined cycle unit, thus reducing FPL's use of natural gas. No additional capacity (MW) will result from the operation of the solar thermal facility.
(8) A number of existing FPL power plants are being temporarily removed from service and placed on Inactive Reserve status. FPL plans to return these units to active service in the future as needed. The timing of the return of these units to full-time active status is uncertain at this time primarily due to the uncertainty regarding FPL's future load. However, for planning purposes, FPL is showing in this document that these units begin to return to active service starting in 2018.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.7 million people. FPL served an average of 4,499,067 customer accounts in thirty-five counties during 2009. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management (DSM), and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at sixteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, Florida. The current generating facilities consist of four nuclear units, three coal units, fourteen combined cycle (CC) units, seventeen fossil steam units, forty-eight combustion gas turbines, one simple cycle combustion turbine and one photovoltaic facility. The location of these eighty-eight firm generating units is shown on Figure I.A.1 and in Table I.A.1. Table I.A.2 provides a "break down" of the capacity provided by the combustion turbine (CT) and steam turbine (ST) components of FPL's existing CC units.

FPL's bulk transmission system is comprised of 6,727 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 585 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

FPL Generating Resources by Location

I.B Firm Capacity Power Purchases

Purchases from Qualifying Facilities (QF):

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five qualifying facilities; i.e., cogeneration/small power production facilities, to purchase firm capacity and energy as shown in Table I.A.2, Table I.B.1, and I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Purchases from Utilities:

FPL has a Unit Power Sales (UPS) contract to purchase 931 MW, with a minimum of 380 MW, of coal-fired generation from the Southern Company (Southern) through May 2010. At the expiration of this contract, another contract with Southern will result in FPL receiving 930 MW from June 2010 through the end of December 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 381 MW (Summer) and 375 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. However, due to Internal Revenue Service (IRS) regulations, the total amount of energy that FPL may receive from this purchase is limited. FPL currently assumes, for planning purposes, that this limit will be reached in the first half of 2016. Once this limit is reached, FPL will be unable to receive firm capacity and energy from these purchases. (However, FPL will continue to receive firm capacity and energy from its ownership portion of the SJRPP units.)

These purchases are shown in Table I.A.2, Table I.B.1, and Table I.B.2. FPL also has ownership interest in the SJRPP units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.

Other Purchases:

FPL has other firm capacity purchase contracts with a variety of Non-QF suppliers. These purchases are generally near-term in nature. Table I.B.1 and I.B.2 present the Summer and Winter MW, respectively, resulting from all firm purchased power contracts discussed above through the year 2019.

Table I.B.1: FPL's Firm Purchased Power Summer MW

I.C Non-Firm (As Available) Energy Purchases

FPL purchases non-firm (as-available) energy from several cogeneration and small power production facilities. Table I.C.1 shows the amount of energy purchased in 2009 from these facilities.

Table I.C.1: As-Available Energy Purchases From Non-Utility Generators in 2009

I.D. Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include a number of conservation/energy efficiency and load management initiatives. FPL's DSM efforts through 2009 have resulted in a cumulative Summer peak reduction of approximately 4,257 MW at the generator and an estimated cumulative energy saving of approximately 51,056 Gigawatt-hour (GWh) at the generator. After accounting for reserve margin requirements, FPL's DSM efforts through 2009 have eliminated the need to construct the equivalent of approximately 13 new 400 MW generating units.

In late 2009, the Florida Public Service Commission (FPSC) imposed new goals for DSM implementation for the period 2010 through 2019. The FPSC-imposed DSM goals for FPL were significantly higher (approximately 225%) than the amount of DSM that was projected in 2009 to meet 100% of FPL's remaining resource needs through 2019. This 2009 projection of FPL's resource needs was based on FPL's 2009 load forecast.

FPL's 2010 load forecast for the 2010 – 2019 time period is substantially lower than FPL's 2009 load forecast. As a result of this lower load forecast, FPL's projected resource needs for 2010 – 2019 have also been lowered substantially below the 2009 projection. Consequently, the amount by which the FPSC-imposed DSM goals exceed FPL's projected resource needs has increased even further.

The impact of this fact on FPL's resource plan is discussed (along with other factors that impact the resource plan) in Chapter III of this document. Also, a discussion of FPL's DSM programs is presented in Chapter III.

System Firm Generating Capacity as of December 31, 2009 [6] =												25,835	24,505

1/ These ratings are peak capability.
2/ These ratings represent Florida Power & Light Company's share of Scherer Unit No. 4, adjusted for transmission losses.
3/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Unit No. 1 and No. 2, excluding Jacksonville Electric Authority (JEA) share of 80%.
4/ Total capability of each unit is 853/839 MW. FPL's ownership share of St. Lucie 1 and 2 is 100%(853/839) and 85% (714/726) respectively as shown above. FPL's share of the deliverable capacity from each unit is approx. 92.5% and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit.
5/ The Total System Generating Cpacity value shown includes FPL-owned firm and non-firm generating capacity.
6/ The System Firm Generating Capacity value shown includes only firm generating capacity.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

II. A. Overview of the Load Forecasting Process

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are typically developed on an annual basis for resource planning work at FPL. New long-term forecasts were developed by FPL in early 2010 that replaced the previous long-term load forecasts that were used by FPL during 2009 in much of its resource planning work and which were presented in FPL's 2009 Site Plan. These new load forecasts are utilized throughout FPL's 2010 Site Plan. These forecasts are a key input to the models used to develop FPL's integrated resource plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

Consistent with past forecasts, the primary drivers to develop these forecasts include economic conditions and weather.

The projections for the national and Florida economies are obtained from the consulting firm IHS Global Insight. Population projections are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects FPL's energy sales and peak demand. Two sets of weather variables are developed and used in FPL's forecasting models:

1. Cooling and Heating Degree-Hours are used to forecast energy sales.
2. Temperature data, along with Cooling and Heating Degree-Hours, are used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Hours are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. A composite temperature hourly profile is derived using hourly temperatures across FPL's service territory. Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained. In developing the composite hourly profile, these regional temperatures are weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Hours, which are based on starting point temperatures of 72° F and 66° F degrees, respectively. Similarly, composite temperature and hourly profile of temperatures are used for the Summer and Winter peak models.

II. B. Comparison of FPL's Current and Previous Load Forecasts

While reflecting somewhat lower growth in the later years of the forecast, FPL's current load forecast is generally in line with the load forecast presented in its 2009 Site Plan. There are two primary factors that are driving the current load forecast: projected population growth, and the lingering effects of the economic recession in Florida.

The customer forecast is based on recent population projections. Population projections are derived from the University of Florida's January 2010 population projections which are lower than prior projections. In fact, in 2009, Florida's population declined for the first time since World War II. According to the University of Florida, net migration has fallen to a record low as a result of the economic slowdown and is expected to remain at historically low levels through 2010, then gradually increase. Consequently, FPL is projecting that customer growth in 2010 will be significantly below its historical average. As population growth recovers, a modest rebound in customer growth is projected in 2011 and 2012. However, population growth is not expected to reach the level historically experienced in Florida until 2014. As a result of lower growth, the total number of customers projected in the current load forecast is below the levels projected in FPL's 2009 Site Plan.

Consistent with the economic assumptions incorporated into the 2009 Site Plan, the state's economy continues to suffer the lingering effects of an economic recession. Over the last year, Florida has lost nearly a quarter-of-a-million jobs and is second only to California in the number of mortgage foreclosures. The severity of current economic conditions suggests that Florida's economic recovery will be gradual. By 2012, the state's economy is projected to resume a more historically typical rate of growth.

Although the projected load growth in the later years of the forecast is generally below that presented in FPL's 2009 Site Plan, the total growth projected for the ten-year reporting period of this document is still significant. The Summer peak is projected to increase to 25,785 MW by 2019, an increase of 3,434 MW over the 2009 actual Summer peak. Likewise, NEL is projected to reach 131,712 GWH in 2019, an increase of 20,408 GWH from the actual 2009 value.

II.C. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class and are adjusted to match the NEL forecast. The results of these sales forecasts for the years 2010 - 2019 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and NEL forecast are outlined below.

1. **Residential Sales**

Residential electric usage per customer is estimated by using an econometric model. Residential sales are a function of: Cooling Degree-Hours, Heating Degree-Hours, lagged Cooling Degree-Hours, lagged Heating Degree-Hours, real price of electricity (a 12-month moving average), Florida real household disposable income, a variable designed to reflect the impact of empty homes, and a dummy variable for the specific month of November 2005. The impact of weather is captured by the Cooling Degree-Hours, Heating Degree-Hours, and the one month lag of these variables. The price of electricity plays a role in explaining electric usage, because electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. To capture economic conditions, the model includes Florida's real household disposable income. The housing crisis has also had an impact on use per customer. Consequently, the model includes a variable designed to capture the impact of empty homes. A dummy variable for November 2005 was included because an analysis of residuals identified that data point as an outlier. Residential energy sales are forecasted by multiplying the residential use per customer forecast by the number of residential customers forecasted.

2. **Commercial Sales**

The commercial sales forecast is also developed using an econometric model. Commercial sales are a function of the following variables: Florida real household disposable income, commercial real price of electricity (a 12-month moving average), Cooling Degree-Hours, Heating Degree-Hours, lagged Cooling Degree-Hours, a variable designed to reflect the impact of empty homes, seasonal dummy variables for the months of February and December, a dummy variable for the specific month of January 2007, and an autoregressive term. Cooling Degree-Hours, Heating Degree-Hours, and the one month lag of Cooling Degree-Hours are used to capture weather-sensitive load in the commercial sector.

3. **Industrial Sales**

The industrial class is comprised of two distinct groups; very small accounts (those with less than 20 kW of demand) and large, traditionally industrial customers. As such, the forecast is developed using a separate econometric model for each group of industrial customer. The small industrial sales model utilizes the following variables: Florida Housing Starts, Cooling Degree-Hours, lagged Cooling Degree-Hours, industrial real price of electricity (a 12-month moving average), and an autoregressive and seasonal autoregressive terms. The Cooling Degree-Hour is used to capture the weather-sensitive load in this group of industrial customers. Florida Housing Starts are reflective of construction activity which comprises a significant portion of this group. The large industrial sales model utilizes the following variables: Florida Housing Starts, industrial real price of electricity (a 12-month moving average), dummy variables for October and November 2004, and an autoregressive term.

4. **Railroad and Railways Sales and Street and Highway Sales**

The projections for railroad and railways sales are based on historical average use per customer because the number of customers is projected to remain the same. This class consists solely of Miami-Dade County's Metrorail system.

The forecast for street and highway sales is developed using historical usage patterns and multiplying these usage levels by the number of forecasted customers.

5. **Other Public Authority Sales**

This revenue class is a closed class with no new customers being added. This class consists of sports fields and a government account. The forecast for this class is based on historical knowledge of its usage characteristics.

6. **Total Sales to Ultimate Customer**

Sales forecasts by revenue class are summed to produce a total sales forecast.

7. **Sales for Resale**

Sales for resale (wholesale) customers are composed of municipalities and/or electric co-operatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers. Currently there are four customers in this class: the Florida Keys Electric Cooperative; City of Key West; Metro-Dade County; and Lee County

Electric Cooperative. In addition, FPL will begin making sales to Seminole Electric Cooperative under a long term agreement in June 2014.

FPL provides service to the Florida Keys Electric Cooperative under a long-term partial requirements contract. The sales to Florida Keys Electric Cooperative are forecasted using a regression model.

FPL's sales to the City of Key West are expected to terminate in 2013. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor.

Metro-Dade County sells 60 MW to Florida Progress. Line losses are billed to Metro-Dade under a wholesale contract.

Lee County has contracted with FPL for FPL to supply a portion of their load beginning in January 2010 and for FPL to supply their total load beginning in January 2014 through December 2033. Forecasted sales to Lee County are based on assumptions regarding their contract demand and expected load factor.

Seminole Electric Cooperative's contract for delivery of 75 MW expired in December 2009. A new contract included in the forecast is for delivery of 200 MW to Seminole Electric beginning in June 2014.

II.D. Net Energy for Load (NEL)

An econometric model is developed to produce a NEL per customer forecast. The key inputs to the model are: the real price of electricity (a 12-month moving average), Cooling and Heating Degree-Hours, and Florida real household disposable income. In addition, the model also includes variables for mandated energy efficiency and a variable designed to capture the impact of empty homes. Seasonal dummies are included for the months of February, July, and December.

The mandated energy efficiency variables are included to capture the impacts of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and compact florescent light bulbs. The estimated impact of these programs for the 2010 to 2019 time period is a reduction, on average, of 7,592 GWh per year. The increase in the number of empty homes resulting from the current housing slump has affected use per customer and is captured in a separate variable. The forecast was also adjusted for additional load estimated from hybrid cars, beginning in 2010, which resulted in an increase of approximately 322 GWh by the end of the ten-year reporting period.

The NEL forecast is developed by multiplying the NEL per customer forecast by the total number of customers forecasted. Once the NEL forecast is obtained, total billed sales are computed using a historical ratio of sales to NEL. The sales by class forecasts previously discussed are then adjusted to match the total billed sales. The forecasted NEL values for 2010 – 2019 are presented in Schedule 3.3 that appears at the end of this chapter.

II.E. System Peak Forecasts

The rate of absolute growth in FPL system peak load has been a function of the size of the customer base, varying weather conditions, projected economic conditions, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient appliances and lighting. FPL developed the peak forecast models to capture these behavioral relationships. Impacts of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the impact of compact fluorescent light bulbs are taken into account in developing the peak forecast. The estimated impact of these federal mandates for the 2010 to 2019 time frame is a reduction of approximately 883 MW (Summer) and 334 MW (Winter) in 2010, and approximately 1,746 MW (Summer) and 941 MW (Winter) by 2019. The forecast was also adjusted for additional load estimated from hybrid cars which resulted in an increase of approximately 65 MW in the Summer and 8 MW in the Winter by the end of the ten-year reporting period.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2010 – 2019 are presented in Schedules 3.1 and 3.2 as well as in Schedules 7.1 and 7.2.

1. **System Summer Peak**

The Summer peak forecast is developed using an econometric model. The variables included in the model are the real price of electricity, Florida real household disposable income, Cooling Degree-Hours in the two days prior to the peak, the average temperature on the day of the peak, and a variable for mandated energy efficiency. The model is based on the Summer peak contribution per customer and is, therefore, multiplied by total customers to derive FPL's system Summer peak.

2. **System Winter Peak**

Like the system Summer peak model, this model is also an econometric model. The model consists of two weather-related variables: the average temperature on the peak day and Heating Degree-Hours for the prior day as well as for the morning of the Winter peak day. In addition, Florida real household disposable income is a variable used in the model. A dummy variable for the year 1996 is also utilized. The forecasted results are adjusted for the impact of mandated energy efficiency. The model is based on the Winter peak contribution per customer and is, therefore, multiplied by total customers to derive FPL's system Winter peak.

3. **Monthly Peak Forecasts**

The forecasting process for monthly peaks consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to the appropriate seasonal peak.

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.F. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2010-2019 are produced using a System Load Forecasting "shaper" program. This model uses years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

II.G. Uncertainty

In order to address uncertainty in the forecasts of aggregate peak demand and NEL, FPL first evaluates the assumptions underlying the forecasts. FPL takes a series of steps in evaluating the input variables, including comparing projections from different sources, identifying outliers in the series, and assessing the series' consistency with past forecasts. In addition, FPL reviews factors which may affect the input variables. This may require reviewing data from local economic development boards or from FPL's own Customer Service Business Unit. Other factors which may be considered include demographic trends and housing characteristics such as starts, size, and vintage of homes.

Uncertainty is also addressed in the modeling process. Generally, econometric models are used to forecast the aggregate peak demand and NEL. During the modeling process, the relevant statistics (goodness of fit, F-statistic, P-values, mean absolute deviation (MAD), mean absolute percentage error (MAPE), etc.) are scrutinized to ensure that the models adequately explain historical variation. Once a forecast is developed, it is compared with past forecasts. Deviations from past forecasts are examined in light of changes in input assumption to ensure that the drivers underlying the forecast are well understood. Finally, forecasts of aggregate peak demand and NEL are compared with their actual values as they become available. An ongoing process of variance analyses is performed. To the extent that the variance analysis identifies large unexplained deviations between the forecast and actual values, revisions to the econometric model may be considered.

The inherent uncertainty in load forecasting is addressed in different ways in regard to FPL's overall resource planning and operational planning work. In regard to FPL's resource planning work, FPL's utilization of a 20% reserve margin criterion (approved by the FPSC) is designed, in part, to maintain reliable electric service to FPL's customers in light of forecasting uncertainty. In regard to operational planning, an extreme weather load forecast for the projected Summer peak day is produced based on maximum historical temperatures on the day of the Summer peak. Likewise, an extreme weather Winter peak forecast is developed by considering minimum historical temperatures at the time of the Winter peak. Statistical analysis on the distribution of historical weather data is performed to evaluate and understand the impact of extreme weather on the peaks and on NEL, and the likelihood of experiencing extreme weather.

It should be noted that despite the downturn in the economy, and negative growth in Florida's population during 2009, FPL experienced a near record Summer peak of 22,351 MW, and an all-time peak of 24,339 MW during the 2009-2010 Winter peak period. These peaks were driven by extreme weather.

II.H. DSM

The effects of FPL's DSM implementation to-date are assumed to be imbedded in the actual usage data for forecasting purposes. Any change in usage pattern, be it the impact of FPL's DSM efforts, price impact, or weather impact, is reflected in the actual observed load data. Therefore, energy efficiency impacts, whether market-driven or as a result of FPL's DSM programs, are assumed to be included in the historical usage data for peaks and NEL.

The impacts of incremental energy efficiency that FPL plans to implement in the future, plus the impacts of FPL's cumulative and incremental load management programs, are accounted for as "line item reductions" to the forecasts as part of the IRP process as shown in Schedules 7.1 and 7.2. After making these adjustments to the load forecasts, the resulting "firm" load forecast is then used in FPL's IRP work.

Schedule 2.1
History and Forecast of Energy Consumption
And Number of Customers by Customer Class

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)

Historical Values (2000 - 2009):
1/ Population represents only the area served by FPL.
2/ Actual energy sales include the impacts of existing conservation. These values are at the meter.
3/ Average No. of Customers is the annual average of the twelve month values.

Projected Values (2010 - 2019):
1/ Population represents only the area served by FPL.
2/ Forecasted energy sales do not include the impact of incremental conservation. These values are at the meter.
3/ Average No. of Customers is the annual average of the projected twelve month values.

2013	22,332	352	21,980	0	1,073	187	1,131	192	19,751
2014	23,575	1,178	22,397	0	1,091	215	1,227	231	20,812
2015	23,924	1,200	22,724	0	1,109	242	1,321	268	20,985
2016	24,344	1,225	23,119	0	1,125	267	1,406	302	21,244
2017	24,774	1,253	23,521	0	1,140	289	1,483	333	21,528
2018	25,328	1,283	24,045	0	1,153	309	1,554	362	21,949
2019	25,785	1,314	24,470	0	1,165	328	1,619	388	22,284

Historical Values (2000 - 2009):

Col. (2) - Col. (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 2000 through 2009 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC), CILC and Commercial /Industrial Demand Reduction (CDR).

Col. (11) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (11) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8).

Projected Values (2010 - 2019):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2010 are incorporated into the load forecast.

Col. (5) - Col. (9) represent all incremental conservation,current load management and incremental load management. These values are projected August values and the conservation values are based on projections with a 1/2010 starting point for use with the 2010 load forecast.

Col (8) represents FPL's Business On Call, CDR,CILC, and Curtailable programs/rates.

Col. (10) represents a "Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.2
History and Forecast of Winter Peak Demand:Base Case

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
January of Year	Total	Firm Wholesale	Retail	Interruptible	Res. Load Management	Residential Conservation	C/I Load Management	C/I Conservation	Net Firm Demand
2000	17,057	142	16,915	0	741	434	438	176	15,878
2001	18,199	150	18,049	0	791	459	448	183	16,960
2002	17,597	145	17,452	0	811	500	457	196	16,329

2009	20,081	162	19,919	0	951	678	764	295	18,366
2010	20,550	376	20,174	0	937	71	768	41	18,734
2011	20,647	381	20,266	0	943	78	784	55	18,788
2012	20,861	386	20,475	0	949	87	804	72	18,949
2013	21,138	392	20,746	0	957	97	827	93	19,163
2014	22,152	1,060	21,092	0	966	108	854	116	20,108
2015	22,745	1,284	21,461	0	975	121	882	141	20,627
2016	23,118	1,311	21,807	0	984	132	908	164	20,929
2017	23,488	1,341	22,147	0	993	143	933	186	21,232
2018	23,889	1,374	22,514	0	1,001	154	957	208	21,569
2019	24,293	1,409	22,884	0	1,007	163	977	225	21,921

Historical Values (2000 - 2009):

Col. (2) - Col. (4) are actual values for historical winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 2000 through 2009 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC), CILC and Commercial /Industrial Demand Reduction (CDR).

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (11) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8) - Col.(9).

Projected Values (2010 - 2019):

Col. (2) - Col. (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2010 are incorporated into the load forecast.

Col. (5) - Col. (9) represent all incremental conservation,current load management and incremental load management. These values are projected August values and the conservation values are based on projections with a 1/2010 starting point for use with the 2010 load forecast.

Col (8) represents FPL's Business On Call, CDR,CILC, and Curtailable programs/rates.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.3
History of Annual Net Energy for Load - GWh: Base Case

(All values are "at the generator" values except for Col (8))

(1) Year	(2) = (5) + (3) + (4) Total Net Energy For Load without DSM	(3) Residential Conservation	(4) C/I Conservation	(5) Actual Net Energy For Load	(6) Sales for Resale GWh	(7) Utility Use & Losses	(8) = (5) - (6) - (7) Actual Total Billed Retail Energy Sales (GWh)	(9) Load Factor(%)
2000	99,097	1,674	1,434	95,989	970	7,059	87,959	61.4%
2001	101,739	1,789	1,545	98,404	970	7,222	90,212	59.9%
2002	107,755	1,917	1,639	104,199	1,233	7,443	95,523	61.9%
2003	112,160	2,008	1,759	108,393	1,511	7,386	99,496	62.9%
2004	112,034	2,106	1,834	108,093	1,531	7,467	99,095	59.9%
2005	115,440	2,205	1,934	111,301	1,506	7,498	102,296	56.8%
2006	117,490	2,312	2,041	113,137	1,569	7,909	103,659	59.2%
2007	118,894	2,373	2,206	114,315	1,499	7,401	105,415	59.4%
2008	115,755	2,485	2,267	111,004	993	7,092	102,919	60.0%
2009	116,221	2,581	2,336	111,304	1,155	7,394	107,671	59.4%

Historical Values (2000 - 2009):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: Col. (2) = Col. (3) + Col. (4) + Col. (5).

Col.(3) & Col.(4) for 2000 through 2009 are DSM values starting in January 1988 and are annual (12-month) values. Col. (3) and Col (4) for 2009 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWh reductions actually experienced each year .

Col. (5) is the actual Net Energy for Load (NEL) for years 2000 - 2009.

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (5) - Col. (6) - Col. (7). These values are at the meter.

Col. (9) is calculated using Col. (5) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (5)*1000) / ((Col.(2) * 8760)
Adjustments are made for leap years.

Forecast of Annual Net Energy for Load - GWh: Base Case

(All values are "at the generator" values except for Col (8))

(1) Year	(2) Forecasted Net Energy For Load without DSM	(3) Residential Conservation	(4) C/I Conservation	(5) = (2) - (3) - (4) Net Energy For Load Adjusted for DSM	(6) Sales for Resale GWh	(7) Utility Use & Losses	(8) = (2) - (6) - (7) Forecasted Total Billed Retail Energy Sales (GWh) without DSM	(9) Load Factor(%)
2010	109,886	193	141	109,552	2,046	7,172	100,668	57.2%
2011	111,634	360	252	111,021	2,145	7,150	102,340	58.5%

SEP	20,334	10,772	21,264	10,780	21,135	10,856
OCT	21,014	9,981	19,809	9,631	19,688	9,684
NOV	19,226	8,676	17,447	8,406	17,530	8,472
DEC	16,122	7,908	17,158	7,915	17,239	7,960
TOTALS		111,304		109,886		111,634

* Forecasted Peaks & NEL do not include the impacts of cumulative load management and incremental conservation and are consistent with values shown in Col. (19) of Schedule 2.3 and Col. (2) of Schedule 3.3.

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990s and has since utilized this approach, in whole or in part as analysis needs warranted, to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of new power plants, the primary subjects of this document, are determined as part of the IRP process work.

This section describes FPL's basic IRP process. Some of the key assumptions, in addition to a new load forecast, that were used in FPL's 2009 and early 2010 resource planning work are also discussed.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental steps to FPL's resource planning. These steps can be described as follows:

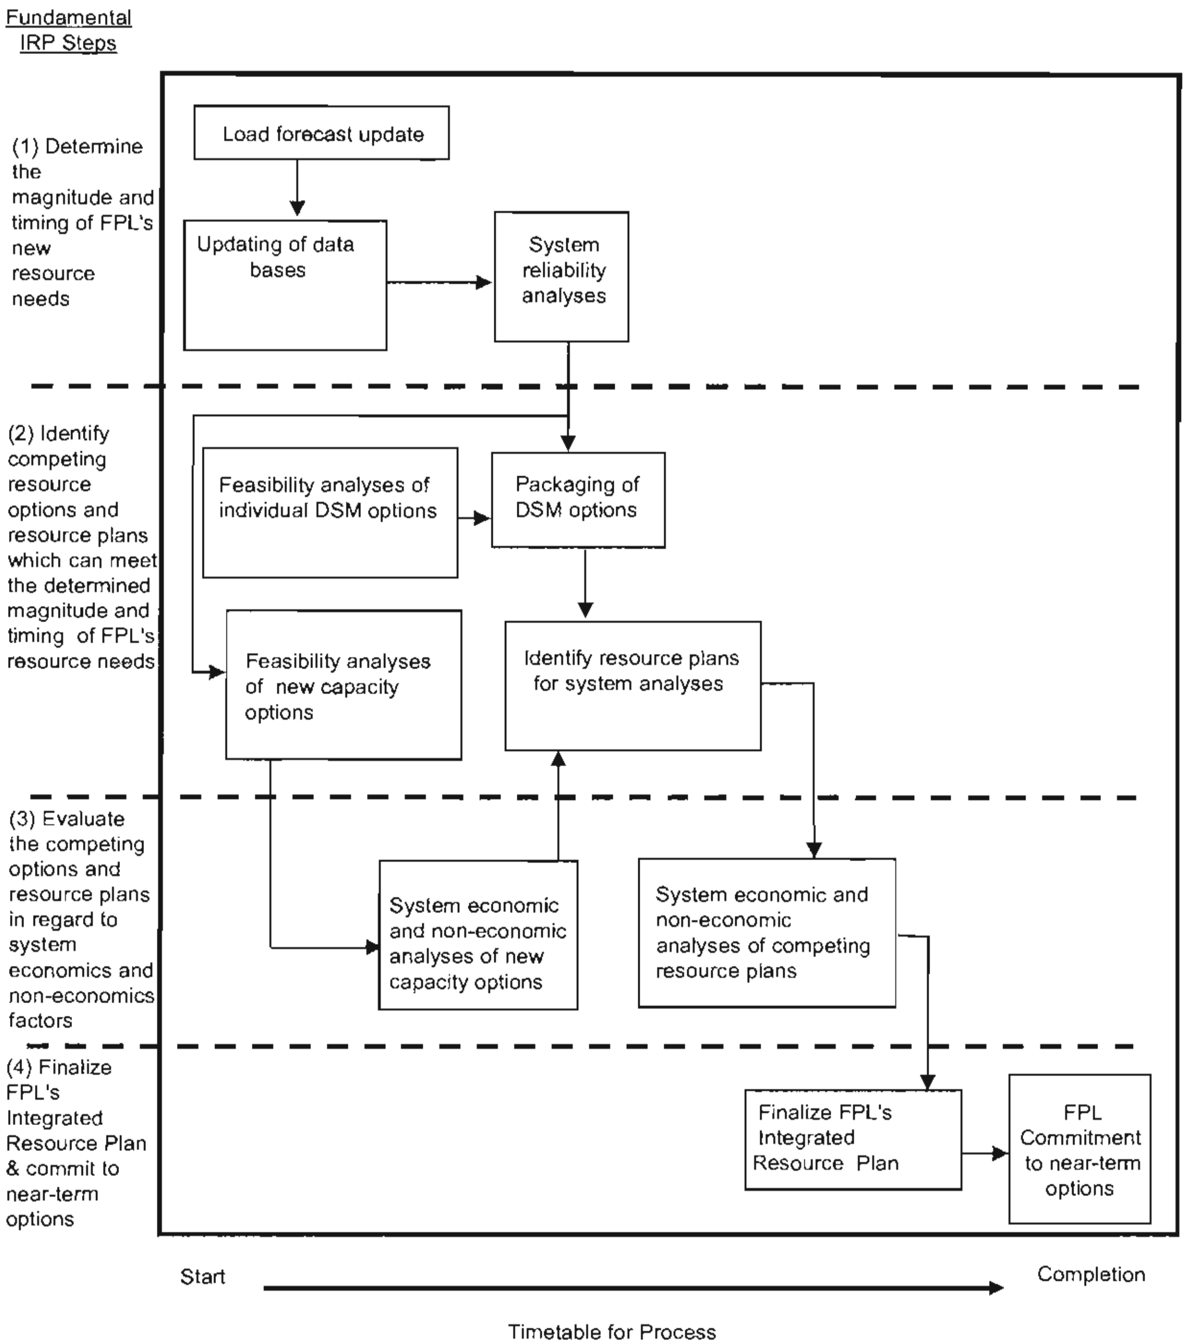
Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Evaluate the competing options and resource plans in regard to system economics and non-economic factors; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.



(Normal time period: approx. 6-7 months)

Figure III.A.1: Overview of FPL's IRP Process

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of the four resource planning steps, determining the magnitude and timing of FPL's resource needs, is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed to maintain system reliability. Also determined in this step is when the MW are needed to meet FPL's reliability criteria. This step is often referred to as a reliability assessment, or resource adequacy, analysis for the utility system.

Step 1 typically starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information that is used in many of the fundamental steps in resource planning. Examples of this new information include, but are not limited to: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) firm capacity power purchases, and (3) DSM implementation.

The first of these assumptions is based on new generating capacity additions that have been approved by the Florida Public Service Commission (FPSC) through Determination of Need proceedings that evaluated both the need for, and the cost-effectiveness of, each of the new capacity additions. These generating capacity additions have also either received the necessary Site Certification approvals from either the Secretary of the Florida Department of Environmental Protection (FDEP) or the Governor and Cabinet (acting as the Siting Board) or, as in the case of the new nuclear units, are in the process of receiving the necessary state and federal approvals. Several new generating unit additions will occur in the 2010 – 2019 reporting time frame of this document.

These generating unit additions include:

- The completion of a third gas-fired CC unit at FPL's West County Energy Center (WCEC) site which is scheduled to come in-service in mid-2011. This new unit, WCEC Unit 3, will add approximately 1,219 MW (Summer) of generation capacity. FPSC approval for this unit was obtained in September 2008 (PSC Order 08-0237-FOF-EI) and site certification was granted in November 2008.

- A new photovoltaic (PV) facility that is currently under construction in Brevard County and which is projected to be completed and in-service in 2010. This PV facility, named the Space Coast Next Generation Solar Energy Center, is projected to have a nameplate rating of 10 MW. The FPSC approved the eligibility of expenditures for this PV facility to be recovered through the Environmental Cost Recovery Clause (ECRC) in August 2008 (PSC Order 08-0941-PAA-EI). The Space Coast Next Generation Solar Energy Center received the Army Corps of Engineers permit in December 2008 and received the Environmental Resource Permit in April 2009.
- A new solar thermal facility at FPL's existing Martin plant site is also under construction and projected to be brought into service in 2010. This solar thermal facility, named the Martin Next Generation Solar Energy Center, which does not add to the capacity (MW) of the Martin plant, is projected to be able to produce up to 75 MW of steam capability, thus reducing use of fossil fuels by FPL when the solar thermal facility is producing steam. The FPSC approved the eligibility of expenditures for this solar thermal facility to be recovered through the ECRC in August 2008 (PSC Order 08-0941-PAA-EI). FPL received the site certification modification approval in August 2008.
- Two existing generating plants, each consisting of two older fossil fuel-fired steam generating units, are currently projected to be modernized by removing the existing generating units and replacing them with new, highly efficient CC units. The new plant at FPL's Cape Canaveral site is projected to be placed in-service in 2013. This new CC unit is projected to have a peak output of 1,210 MW. This new plant will be called the Cape Canaveral Next Generation Clean Energy Center. The new plant at FPL's Riviera site is projected to be placed in-service in 2014. This new CC unit is projected to have a peak output of 1,212 MW. This new plant will be called the Riviera Beach Next Generation Clean Energy Center. These conversions were approved by the FPSC in September 2008 (PSC Order 08-0591-FOF-EI). The site certification application for Cape Canaveral was filed in December 2008 and granted in October 2009. The site certification application for Riviera Beach was filed in February 2009 and granted in November 2009.

  As FPL has recently stated, work on these modernization projects has been suspended.

- In addition, FPL will be adding approximately 400 MW of generating capacity at its existing nuclear power plants at the Turkey Point and St. Lucie sites. This added capacity is scheduled to come in-service in 2011 and 2012, respectively. These capacity "uprates" were approved by the FPSC in January 2008 (PSC Order 08-0021-FOF-EI). The Final Order for the Site Certification was issued in September 2008 for the St. Lucie uprates and October 2008 for the Turkey Point uprates.

These new generating units and generating capacity additions were selected for a variety of reasons including cost-effectiveness, significant system fuel savings, fuel diversity, and significant system emission reductions, including greenhouse gas emission reductions. In addition, the solar projects will increase the contribution of renewable energy sources towards meeting the electricity needs of FPL's customers.

The second of these assumptions involves firm capacity power purchases. FPL's current projection of firm capacity purchases is very similar to the projection shown in FPL's 2009 Site Plan, after accounting for the fact that the contracts for several purchases presented in the 2009 Site Plan have now ended. These firm capacity purchases are from a combination of utility and independent power producers. Details, including the annual total capacity values for these purchases, are presented in Chapter I in Tables I.B.1 and I.B.2. These purchased capacity amounts were incorporated in FPL's resource planning work.

The third of these assumptions involves a projection of the amount of additional demand side management (DSM) that is anticipated to be implemented annually over the ten-year period. Since 1994, FPL's resource planning work has assumed that, at a minimum, the DSM MW called for in FPL's approved DSM Goals will be achieved as planned. The resource plan presented in FPL's 2010 Site Plan accounts for the new DSM goals.

The amount of DSM included in the 2010 Site Plan is different than the amount included in the 2009 Site Plan. In late 2009, the FPSC imposed significantly higher goals for DSM resources for FPL to add in the 2010 – 2019 period. The amount of demand (MW) reduction from the new DSM goals far exceeds (i.e., is more than double) the 2009 projection of FPL's remaining resource needs through 2019. Now, with FPL's lower long-term 2010 load forecast, and the commensurately lower 2010 projection of resource needs, the amount by which the MW reductions from the new DSM goals exceeds FPL's resource needs is even larger.

These key assumptions, plus the other updated information described above, are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's future resource needs. This determination is accomplished by system reliability analyses which for FPL are currently based on dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the reliability of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss-of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program used by FPL.

The result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. Information regarding the timing and magnitude of these resource needs is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analyses of new capacity options are conducted to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs. In similar analyses, feasibility analyses of new DSM options and/or continued growth in existing DSM options are typically conducted.

The individual new resource options emerging from these feasibility options are then typically "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using spreadsheet, dynamic programming, and/or linear and non-linear programming techniques.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs are identified.

Step 3: Evaluate the Competing Options and Resource Plans in Regard to System Economics and Non-Economic Factors:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for evaluating these resource options and resource plans. In 2009, once the resource plans were developed, FPL utilized the P-MArea production cost model and a Fixed Cost Spreadsheet to perform the economic analyses. The P-MArea model is the model used by FPL to develop the Fuel Cost Budget and to conduct other production cost-related analyses.

FPL also utilized several other models in the economic evaluation portion of its resource planning work. For analyses of individual DSM options, FPL typically uses its DSM cost-effectiveness model which is an FPL spreadsheet model utilizing the FPSC's approved methodology for analyzing the cost-effectiveness of individual DSM measures/programs, and its non-linear programming model for analyzing the potential for lowering system peak loads through additional load management capacity. FPL then utilizes its linear programming model to develop DSM portfolios.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases in which the DSM contribution was assumed as a given and the only competing options were new generating units and/or purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans in such cases were evaluated on a cumulative present value revenue requirement (CPVRR) basis.

Other factors are also included in FPL's evaluation of resource options and resource plans. While these factors may have an economic component or impact, they are often discussed in quantitative, but non-economic terms, such as percentages, tons, etc. rather than in terms of dollars. These factors are often referred to by FPL as "system concerns" that include (but are not necessarily limited to) maintaining/enhancing fuel diversity in the FPL system, system emission levels, and maintaining a regional balance between load and generating capacity, particularly in Southeastern Florida. In conducting the evaluations needed to determine which resource options and resource plans are best for FPL's system, both the economic and non-economic evaluations are conducted with an eye to whether the system concern is positively or negatively impacted by a given resource option or resource plan.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps were used to develop the future generation plan. This plan is presented in the following section.

III.B Incremental Resource Additions/Changes

FPL's projected incremental generation capacity additions/changes for 2010 through 2019 are depicted in Table III.B.1. These capacity additions/changes result from a variety of actions including: changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls), temporarily removing older, less efficient generating units from active service and placing them into Inactive Reserve status until their continued operation is again needed, changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, increases in generating capacity at FPL's four existing nuclear units, the projected modernizations of FPL's steam generating units at its existing Cape Canaveral and Riviera sites into new, very fuel-efficient CC generating units, and by construction of approved new generating units such as West County Energy Center (WCEC) Unit 3.

As shown in Table III.B.1, the capacity additions consist primarily of construction of one new CC unit, the projected modernization of existing steam units into new CC units, and capacity increases at FPL's existing nuclear generating units. (The DSM additions that are consistent with the DSM goals imposed by the FPSC through 2019 are not explicitly presented in this table, but have been accounted for in FPL's resource planning work. In addition, the projected MW reductions from these DSM additions are reflected in the projected reserve margin values shown in the table.)

This table also shows the addition of the previously discussed 85 MW of new solar facilities (10 MW of PV and 75 MW of solar thermal). However, as indicated in the table and its footnotes, these new solar facilities are not projected to contribute new firm capacity. There are two reasons for this. First, one of these facilities – the 75 MW solar thermal facility at the Martin site – is designed not to add new capacity, but to serve solely as a "fuel substitute" facility. (When sufficient sunlight is available, the solar thermal facility will produce steam that would otherwise have been produced by burning fossil fuels.) Second, in regard to the new PV facility that has a 10 MW nameplate rating, it is unclear at this time what the output of this facility will consistently be during FPL's late afternoon Summer and early morning Winter peak hours. Consequently, FPL is not assigning a firm capacity value (i.e., those values reflected in Table III.B.1) to this PV facility at this time. Once FPL has actual operating experience with this PV facility, it will evaluate what an appropriate firm capacity value for this facility should be. However, FPL's economic and non-economic analyses fully capture the system fuel and emission savings from both of these two new solar facilities.

The significantly lower long-term load forecast, coupled with the approved additions of highly efficient new natural gas-fired and nuclear generating capacity, and the new DSM goals imposed by the FPSC, allow the opportunity for FPL to temporarily remove some older, less efficient generating capacity from active service, resulting in savings in operational and maintenance costs. A number of such units are/will be on Inactive Reserve status in 2010. These units are: Cutler Units 5 & 6, Sanford Unit 3, Port Everglades Units 1 & 2, and Turkey Point Unit 2. In 2011, Port Everglades Units 3 & 4 are also projected to be placed on Inactive Reserve. These generating units will continue to be maintained and will be returned to active service when needed. The timing of the return of these units is uncertain at this time primarily due to the uncertainty regarding FPL's future load. However, for planning purposes, FPL is showing in this document that these units begin to return to active service starting in the latter years of the ten-year reporting period, 2018 and 2019.

In addition, the existing Cape Canaveral and Riviera units that would be removed as part of the projected modernization work, will initially be placed on Inactive Reserve status, then would be completely removed from service in preparation for the construction of the new CC units at those sites if the modernization projects proceed.

Finally, as shown in the table below, FPL is currently projecting no additional new generating units beyond those discussed above for the years 2015 through 2019. This result is primarily driven by the combination of the lower long-term 2010 load forecast and the higher DSM goals.[2]

[2] For purposes of establishing a Standard Offer Contract, and using the same forecasts and other assumptions presented in this document, FPL projects that it's next fossil-fueled new generating unit would be a Greenfield 3x1 H CC with a 2025 in-service date. Details of that unit are not provided in this Site Plan because its projected in-service date is beyond the 2010-2019 time period addressed in this document.

Table III.B.1: Projected Capacity Changes for FPL

Projected Capacity Changes and Reserve Margins for FPL [1]			
Year	*Projected Capacity Changes*	*Net Capacity Changes (MW)* Winter [2]	Summer [3]
2010	Martin Next Generation Solar Energy Center (Solar Thermal) [7]	—	—
	Space Coast Next Generation Solar Energy Center (PV) [6]	—	—
	Changes to Existing Purchases [4]	—	(50)
	Riviera Unit 3 - offline for modernization	(280)	(277)
	Riviera Unit 4 - offline for modernization	(291)	(288)
	Cape Canaveral Unit 1 - offline for modernization	—	(396)
	Cape Canaveral Unit 2 - offline for modernization	—	(396)
	Changes to Existing Units	149	15
	Inactive Reserve of Existing Units - offline [8]	(775)	(769)
2011	Changes to Existing Purchases [4]	(90)	(45)
	Cape Canaveral Unit 1 - offline for modernization	(398)	—
	Cape Canaveral Unit 2 - offline for modernization	(398)	—
	West County Unit 3 [5]	—	1,219
	Inactive Reserve of Existing Units - offline [8]	(394)	(1,171)
	Changes to Existing Units	0	0
2012	Changes to Existing Purchases [4]	—	(100)
	West County Unit 3 [5]	1,335	—
	Changes to Existing Units	3	3
	Inactive Reserve of Existing Units - offline [8]	(783)	—
	Existing Nuclear Units Capacity Uprates - St. Lucie 1	103	103
	Existing Nuclear Units Capacity Uprates - St. Lucie 2	—	88
	Existing Nuclear Units Capacity Uprates - Turkey Point 3	—	104
2013	Changes to Existing Purchases [4]	(180)	—
	Cape Canaveral Next Generation Clean Energy Center	—	1,210
	Existing Nuclear Units Capacity Uprates - St. Lucie 2	88	—
	Existing Nuclear Units Capacity Uprates - Turkey Point 3	104	—
	Existing Nuclear Units Capacity Uprates - Turkey Point 4	104	104
2014	Cape Canaveral Next Generation Clean Energy Center	1,355	—
	Riviera Beach Next Generation Clean Energy Center	—	1,212
2015	Riviera Beach Next Generation Clean Energy Center	1,344	—
2016	Changes to Existing Purchases [4]	(931)	(1,306)
2017	Changes to Existing Purchases [4]	(375)	—
2018	Inactive Reserve of Existing Units - online [8]	0	392
2019	Inactive Reserve of Existing Units - online [8]	394	387
	TOTALS =	**84**	**39**

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.

(2) Winter values are forecasted values for January of the year shown. FPL's actual 2010 Winter peak was significantly higher than forecasted.

(3) Summer values are forecasted values for August of the year shown.

(4) These are firm capacity and energy contracts with QF, utilities, and other entities. See Table I.B.1 and Table I.B.2 for more details.

(5) All new unit additions are scheduled to be in-service in June of the year shown. All additions assumed to start in June are included in the Summer reserve margin calculation starting in that year and in the Winter reserve margin calculation starting with the next year.

(6) Because of the intermittent nature of the photovoltaics (PV) resource, FPL is currently assigning no firm capacity benefit to these generating additions. FPL will reassess this once actual operating data from the PV facilities at these locations is available. This location-specific information is needed in order to gauge consistent output during the peak hours which are accounted for in FPL's reserve margin calculations.

(7) The Martin solar thermal facility is designed to provide steam for FPL's existing Martin Unit 8 combined cycle unit, thus reducing FPL's use of natural gas. No additional capacity (MW) will result from the operation of the solar thermal facility.

(8) A number of existing FPL power plants are being temporarily removed from service and placed on Inactive Reserve status. FPL plans to return these units to active service in the future as needed. The timing of the return of these units to full-time active status is uncertain at this time primarily due to the uncertainty regarding FPL's future load. However, for planning purposes, FPL is showing in this document that these units begin to return to active service starting in 2018.

III.C Issues Impacting FPL's Resource Planning Work

As indicated in the Executive Summary, FPL's resource planning efforts in 2010 will continue to be influenced by three factors: (i) a new lower long-term load forecast, (ii) significantly increased DSM goals for the 2010-2019 time frame, and (iii) regulatory and commercial developments regarding FPL's new nuclear units, Turkey Point 6 & 7.

In addition, there are other items that will also influence FPL's resource planning work. Among these other items are two that FPL typically refers to as on-going system concerns that FPL has considered in its resource planning work for a number of years. These two on-going system concerns are: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida.

A third factor that will influence FPL's on-going resource planning efforts is the Executive Order directive issued in 2007 by Governor Crist, calling for reductions in greenhouse gas emissions and for increased contribution from renewable energy sources.

A fourth factor that could affect FPL's resource planning is the future establishment of Florida standards for renewable or clean energy contributions to a utility system. A Renewable Portfolio Standard (RPS) proposal was prepared by the FPSC, and sent to the Florida Legislature for consideration, with a possible change to a Clean Portfolio Standard (CPS), during the 2009 legislative session. However, no RPS or CPS legislation was enacted during the 2009 legislative session. RPS or CPS legislation, or other legislative initiatives regarding renewable or clean energy contributions, may occur in the future. If such legislation is enacted in 2010 or later years, FPL will then determine what steps need to be taken to address the legislation. Such steps would then be discussed in FPL's Site Plan in the year following the enactment of such legislation.

These four (4) factors that impact FPL's on-going resource planning work are briefly discussed below.

1. System Fuel Diversity

FPL is currently dependent upon using natural gas to generate slightly more than half of the electricity it delivers to its customers. In the future, the percentage of FPL's electricity that is generated by natural gas is projected to increase. Therefore, FPL is continually seeking opportunities to maintain and enhance the fuel diversity of its system.

In 2007, FPL sought approval from the FPSC to add two new advanced technology coal units to its system. These two new units would have been placed in-service in 2013 and 2014. However, due to concerns over greenhouse gas emissions, FPL was unable to obtain approval for these units. Consequently, FPL does not believe that new advanced technology coal units are viable fuel diversity enhancement options in Florida for the foreseeable future.

Therefore, FPL has turned its attention to nuclear energy, renewable energy, and more efficient ways in which to generate electricity using natural gas in order to enhance its fuel diversity. In regard to nuclear energy, FPL obtained approval to increase capacity at each of its four existing nuclear units. In total, these capacity "uprates" will add approximately 400 MW of capacity and energy for FPL's customers beginning in the 2011/2012 time period. In 2008, the FPSC approved both the need for these uprates and the ability to recover uprates-related expenditures.

FPL also has been involved in activities to investigate adding or maintaining renewable resources as a part of its generation supply. One of these activities is a variety of discussions with the owners of existing facilities aimed at maintaining or extending current agreements that are scheduled to end during the ten-year reporting period of this document. Another activity is to periodically issue a request for proposals to solicit cost-effective new renewable projects from outside parties. Also, as previously discussed, FPL sought and received approval from the FPSC in 2008 to add 110 MW through three new FPL-owned solar facilities, one solar thermal facility and two PV facilities. One 25 MW PV facility began commercial operation in 2009. The remaining two solar facilities are scheduled to be in-service by the end of 2010. FPL's efforts to utilize renewable energy are discussed further in Section III.F.

In regard to using natural gas more efficiently, FPL received approvals in 2008 from the FPSC to build a third highly efficient CC unit at its West County Energy Center site (WCEC Unit 3) and to convert the older steam generating units at its existing Cape Canaveral and Riviera plant sites to new, highly efficient CC units. WCEC Unit 3 is currently projected to go in-service in 2011.

In the future, FPL will continue to identify and evaluate alternatives that may maintain or enhance system fuel diversity. FPL also plans to maintain the ability to utilize fuel oil at those existing units that have that capability, although cost factors currently limit the expected use of these facilities. Furthermore, FPL has traditionally purchased the gas transportation capacity required for new natural gas generating units from an existing natural gas pipeline company. As an alternative, FPL sought approval in 2009 from the FPSC for the construction of a new natural gas pipeline in Florida capable of serving future generation needs. Such a third pipeline was projected to have potential benefits for FPL and its customers by increasing the diversity of FPL's fuel supply sources, increasing the physical reliability of the pipeline delivery system, and enhancing competition among pipelines. However, the application for an FPL-owned pipeline was denied by the FPSC in 2009. FPL is currently re-evaluating how natural gas can be delivered to its system in the future.

2. **<u>Southeastern Florida Imbalance</u>**

In recent years, an imbalance had developed between regionally installed generation and peak load in Southeastern Florida. A significant amount of energy required in the Southeastern Florida region during peak periods was being provided through the transmission system from plants located outside the region. FPL's prior planning work concluded that either additional installed generating capacity in this region, or transmission capacity capable of delivering additional electricity from outside the region, would be required to address this imbalance.

Partly because of the lower transmission-related costs resulting from their location, four recent capacity addition decisions (Turkey Point Unit 5 and WCEC Units 1, 2, & 3) were evaluated as the most cost-effective options to meet FPL's capacity needs in the near-term. Adding these units will significantly reduce the imbalance between generation and load in Southeastern Florida.

In addition, FPL will be adding increased capacity at FPL's existing two nuclear units at Turkey Point in 2011 and 2012 and is currently projected to increase the generating capacity at its Riviera site through a modernization of that site in 2014. These generating unit additions in Southeastern Florida are expected to address the imbalance for most, if not all, of the 2010-2019 reporting period addressed in this document even after accounting for temporarily placing some of the existing generating units in the region on Inactive Reserve status. However, the Southeastern Florida imbalance will remain a consideration in FPL's on-going resource planning work.

3. **<u>Governor Crist's Executive Order</u>**

The Executive Order directive issued in 2007, particularly the portions of the directive that call for significant increases in renewable, non-emitting energy, and decreases in greenhouse gas emissions, are being addressed by FPL in a variety of ways. With respect to renewable energy, FPL's efforts to build its own renewable energy facilities were mentioned above in regard to fuel diversity and are also discussed in more detail in Section III.F.

These renewable energy efforts have the potential to help lower greenhouse gas emissions. In addition, significant reductions, particularly of carbon dioxide (CO_2), will be accomplished in the ten-year reporting time frame of this document by the approved capacity uprates at FPL's four existing nuclear power plants. Further reductions in greenhouse gas emissions are also expected from increasing the overall fuel efficiency of FPL's system through the addition of WCEC Unit 3 and the currently projected modernizations of FPL's existing Cape Canaveral and Riviera plant sites. FPL will also continue to look for cost-effective ways to further improve the efficiency of its system that will lead to even more greenhouse gas emission reductions.

FPL's system CO_2 emission rate (amount of CO_2 emitted per MWh of electricity generated) is already relatively low due in large part to the overall efficiency of FPL's system. The efforts described above have the potential not only to continue the trend of steadily lowering FPL's already low CO_2 emission rate, but also to begin to lower total system CO_2 emissions despite continued growth in population.

4. <u>Renewable Portfolio or Clean Energy Standards (RPS or CPS)</u>

At the time this document is being prepared, Florida does not have a Renewable or Clean Energy Portfolio Standard (RPS or CPS). An RPS proposal was prepared by the FPSC and sent to the Florida Legislature for their consideration, with a possible change to a Clean Portfolio Standard (CPS), during the 2009 legislative session. However, no RPS or CPS legislation was enacted during that session. RPS or CPS legislation, or other legislative initiatives regarding renewable or clean energy contributions, may occur in the future. If such legislation is enacted in 2010 or in a later year, FPL will then determine what steps need to be taken to address the legislation. Such steps would then be discussed in FPL's Site Plan in the year following the enactment of such legislation.

III.D Demand Side Management (DSM)

As previously discussed in Chapter I, and earlier in this chapter, the FPSC in late 2009 imposed significantly higher DSM goals for FPL for 2010 – 2019 than are needed to meet 100% of FPL's remaining resource needs through 2019. In addition, the FPSC ordered

FPL to spend up to $15.5 million per year to promote DSM-based applications of solar water heating and photovoltaics (PV).

The DSM goals recently imposed by the FPSC have three components: Summer MW reductions, Winter MW reductions, and GWh reductions. Table III.D.1 presents the Summer MW reduction component of these goals. (The Summer MW component, and to a much lesser degree the Winter MW reduction component, impacts FPL's need for future resources such as those discussed in this document. The GWh reduction component has no impact on FPL's need for future resources.)

Table III.D.1: FPL's Summer MW Reduction Goals for DSM
(at the Generator)

Year	Cumulative Summer MW DSM Goals for FPL (at Generator)
2010	110
2011	253
2012	419
2013	599
2014	783
2015	955
2016	1,111
2017	1,251
2018	1,379
2019	1,498

By March 30, 2010, FPL is required to petition the FPSC for approval of the DSM Plan it proposes to implement to meet the DSM goals and renewable energy expenditure mandates. At the time this Site Plan is being prepared, FPL was still developing its DSM Plan that it will petition the FPSC for approval to implement. FPL expects that the FPSC approval process for its DSM Plan will likely take several months. Therefore, FPL does not expect to know with certainty what its portfolio of approved DSM programs will be until mid-2010 at the earliest. FPL expects to provide a description of its approved DSM programs in its 2011 Site Plan.

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include both conservation initiatives and load management. FPL's DSM efforts through 2009 have resulted in a cumulative Summer peak reduction of approximately 4,257 MW at the generator and an estimated cumulative energy saving of approximately

51,055 Gigawatt Hour (GWh) at the generator. Accounting for reserve margin requirements, FPL's DSM efforts through 2009 have eliminated the need to construct approximately 13 new 400 MW generating units.

FPL has consistently been among the leading utilities nationally in DSM achievement. For example, according to the U.S. Department of Energy's 2007 data (the last year for which the DOE data was available at the time this Site Plan is being developed), FPL ranked # 1 nationally in energy efficiency demand reduction and # 2 nationally in load management demand reduction. And, importantly, FPL has achieved these significant DSM accomplishments while minimizing the impact on electric rates for all of its customers.

FPL's intent is to address the FPSC's DSM goals and funding mandate for DSM-based solar applications, to continue its national leadership role in DSM, and to continue to minimize the electric rate impact resulting from its DSM efforts.

III.E Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy to FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV bulk transmission lines that must be certified under the Transmission Line Siting Act.

Table III.E.1: List of Proposed Power Lines

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (KV)	(7) Capacity (MVA)
FPL	St. Johns 1/	Pringle	25	Dec - 13	230	759
FPL	Manatee 2/	BobWhite	30	Dec - 12	230	1190

1/ Final order certifying the corridor was issued on April 21, 2006. This project is to be completed in two phases. Phase I consisted of 4 miles of new 230kV line (Pringle to Pellicer) and was completed in May-2009. Phase II consists of 21 miles of new 230kV line (St. Johns to Pellicer) and is scheduled to be completed by Dec-2013.

2/ Final order certifying the corridor was issued on November 6, 2008. This project consists of 30 miles of new 230kV line (Manatee to Bobwhite) and is scheduled to be completed by Dec-2012

In addition, there will be transmission facilities needed to connect several of FPL's projected generating capacity additions to the system transmission grid. These transmission facilities for the projected generating capacity additions at the West County Energy Center site Unit 3, the capacity increases (uprates) at the existing St. Lucie and Turkey Point nuclear sites, and the Cape Canaveral and Riviera Beach modernizations are described on the following pages.

Certain new generation additions will not need new transmission facilities. These generation additions include the Martin Next Generation Solar Energy Center and the Space Coast Next Generation Solar Energy Center. The Martin solar thermal facility does not add any new generation capacity at the site and, therefore, no new transmission facilities are required. The Space Coast facility is an addition of 10 MW of PV generation that will be connected at distribution voltage at the Grissom substation. No new transmission facilities are needed.

In regard to the existing generating units that are projected to be temporarily placed on Inactive Reserve status in 2010 and 2011, there are no projected impacts to FPL's transmission system from these units because these units can be returned to active service with adequate notice.

III.E.1 Transmission Facilities for West County Energy Center (WCEC) Unit 3

The work required to connect West County Energy Center (WCEC) Unit 3 in 2011 to the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Build new Sugar 230 kV Substation on WCEC site.
3. Construct two string busses to connect the collector busses to Sugar 230kV Substation.
4. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
5. At Corbett Substation, relocate Germantown 230 kV line terminal from Corbett to Sugar Sub.
6. At Corbett Substation, relocate Broward/Yamato 230 kV line terminal from Corbett to Sugar Sub.
7. At Corbett Substation, install new Sugar 230 kV line terminal in Bay 2W.
8. At Corbett Substation, install one 5-ohm inductor on the 230 kV side of the 500/230 kV autotransformer.
9. Add relays and other protective equipment.

II. Transmission:

1. Relocate Germantown 230 kV line from Corbett to Sugar.
2. Relocate Broward/Yamato 230 kV line from Corbett to Sugar.
3. Construct one mile 230 kV 1190 MVA line from Sugar to Corbett.

III.E.2 Transmission Facilities for St. Lucie Units 1 & 2 Capacity Uprates

The work required to address the St. Lucie Units 1 & 2 uprates in 2011 for Unit 1, and in 2012 for Unit 2, in regard to the FPL grid is projected to be as follows:

I. Substation:

1. At Midway Substation, replace eleven 230 kV disconnect switches, and six wave traps. Also upgrade associated jumpers, bus work and equipment connections.
2. At St. Lucie Switchyard, replace eighteen 230 kV disconnect switches and six wave traps.
3. Uprate the Unit 1A and 1B main step-up transformers to 635 MVA.
4. Uprate the spare main step-up transformer to 635 MVA to replace Unit 2A main step-up transformer.
5. Replace the Unit 2B main step-up transformer with a new one rated at 635 MVA.
6. Add relays and other protective equipment.

II. Transmission:

1. Upgrade the three existing St. Lucie-Midway 230 kV lines with spacers between the conductors to achieve a normal (continuous) rating of 2790 Amperes.
2. Replace one existing overhead ground wire on each of the three existing St. Lucie Midway 230kV line with fiber optic overhead ground wire for protective relay communication.

III.E.3 Transmission Facilities for Turkey Point Units 3 & 4 Capacity Uprates

The work required to address the Turkey Point Units 3 & 4 uprates in 2012 in regard to the FPL grid is projected to be as follows:

I. Substation:

1. At Turkey Point Switchyard, install two 5-Ohm series phase inductors combined with external shunt capacitors on the southeast and southwest 230 kV operating busses.
2. At Turkey Point Switchyard, replace twelve 230 kV disconnect switches. Also upgrade associated jumpers, bus work and equipment connections.
3. Uprate the Unit 3 and Unit 4 main step-up transformers to 970 MVA.
4. Replace spare main step-up transformer with 1028 MVA transformer.
5. Add relays and other protective equipment.
6. Replace breaker failure panels at Davis Substation.
7. Replace breaker failure panels at Flagami Substation.

II. Transmission:

1. Upgrade the existing string busses for both Units 3 & 4 between the main step-up transformers and the switchyard with spacers between the conductors.

III.E.4 Transmission Facilities for Cape Canaveral Next Generation Clean Energy Center (Projected Modernization)

The work required to connect the projected Cape Canaveral Next Generation Clean Energy Center in 2013 to the FPL grid is forecasted to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Construct two string busses to connect the collector busses to Cape Canaveral 230kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. At Cape Canaveral Switchyard replace eight 230 kV disconnect switches. Also upgrade associated jumpers, bus work and equipment connections.
5. Expand switchyard relay vault and add relays and other protective equipment.

II. Transmission:

1. Relocate the Cape Canaveral-Grissom 115 kV line.

III.E.5 Transmission Facilities for Riviera Beach Next Generation Clean Energy Center (Projected Modernization)

The work required to connect the projected Riviera Beach Next Generation Clean Energy Center in 2014 to the FPL grid is forecasted to be as follows:

I. Substation:

1. Expand the Riviera 230 kV Switchyard five breakers to accommodate terminals for one combustion turbine (CT), and one steam turbine (ST).
2. Construct a new 138 kV Riviera Switchyard - five bays, 14 breakers with terminals to connect two CT units and seven 138 kV lines.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. Add relays and other protective equipment.
5. At Ranch Substation, add a new 230 kV bay 5 and upgrade bay 4 to 3000 Amperes.
6. Breaker replacements:
   Ranch Substation – Replace one 230 kV breaker
   Broward Substation – Replace one 230 kV breaker

II. Transmission:

1. Break the Indiantown-Riviera 230kV and extend each of the line segments south (approx. 4 miles) to connect to the Ranch 230 kV Substation forming Indiantown-Ranch and a Ranch-Riviera 230 kV circuits.
2. Remove Corbett-Ranch #2 230 kV line at Ranch and:
   a. extend to meet the Cedar-Lauderdale 230 kV line N/S corridor (approx. 10 miles).
3. Break Cedar -Corbett 230 kV (near Ranch Sub in Corbett-Jog section) and:
   a. Extend Cedar side to Riviera, (approx. 15 miles) creating new Cedar-Riviera 230 kV.
   b. Extend Corbett side to meet the Cedar-Lauderdale 230 kV N/S corridor (approx. 10 miles).
4. Break Cedar-Lauderdale 230 kV (near 230 corridor running N/S)
   a. Connect Cedar side to meet 3.b. to create a Cedar to Corbett 230 kV.
   b. Connect Lauderdale side to meet 2.a. to create a Corbett to Lauderdale 230 kV.
5. Upgrade the existing IBM-Yamato 138 kV line to 1200 Amperes.
6. New underground 138 kV tie line between new Riviera 138 kV Switchyard and 560 MVA, 230/138 kV autotransformer in the expanded Riviera 230 kV Substation.
7. Relocate six existing 138 kV lines from existing Ranch 138 kV Switchyard to new Riviera 138 kV Switchyard.

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various renewable energy technologies. For purposes of discussing FPL's renewable energy efforts in this document, those efforts will be placed into five categories.

1) **Early Research & Development Efforts:**

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970s in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities in Florida on both a daily and annual basis. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-kilowatt (kW) system was placed into operation in 1984. (The system was removed in 1990 to make room for substation expansion once testing of this PV installation had been completed.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. This FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed below).

2) **Demand Side & Customer Efforts:**

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program ended (due to the fact that it was no longer cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980s, FPL introduced another renewable energy program, FPL's Passive Home Program. This program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for six passive home designs with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the FPSC to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test were deemed to be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

FPL has since continued to analyze and promote the utilization of PV. These efforts have included a PV research, development, and education project, "green energy" research projects and pricing programs, and participation in the State of Florida's PV for Schools program. With resources from the FPL Group Foundation, FPL will contribute 30 kw of PV to schools and educational non-profits in its service area during 2010. This initiative also delivers teacher training and curriculum that is tied to the Sunshine Teacher Standards in Florida. Additionally, it provides teacher grants to promote and fund projects in the classrooms.

FPL has also been investigating fuel cell technologies through monitoring of industry trends, discussions with manufacturers, and direct field trials. From 2002 through the end of 2005, FPL conducted field trials and demonstration projects of Proton Exchange Membrane (PEM) fuel cells with the objectives of serving customer end-uses while evaluating the technical performance, reliability, economics, and relative readiness of the PEM technology. The demonstration projects were conducted in partnership with customers and included 5 locations. The research projects were useful to FPL in identifying specific issues that can occur in field applications and the current commercial viability of this technology. FPL will continue to monitor the progress of these technologies and conduct additional field evaluations as significant developments in fuel cell technologies occur.

In addition, FPL assists customers who are interested in installing PV equipment at their facilities. Consistent with Florida Administrative Code Rule 25-6.065, Interconnection and Net Metering of Customer-Owned Renewable Generation, FPL works with customers to interconnect these customer-owned PV systems. Through December 2009, approximately 645 customer systems (predominantly residential) have been interconnected.

Finally, as part of its DSM goals decision, the FPSC imposed a requirement for Florida's investor-owned utilities to spend up to a set, not-to-exceed amount of money annually to facilitate demand side solar water heater and photovoltaic applications. FPL's not-to-exceed annual amount of money for these applications is approximately $15.5 million. At the time this Site Plan is being prepared, FPL is developing its plan for how these expenditures will be made and is scheduled to file its plan for FPSC approval on March 30, 2010. The FPSC is expected to approve FPL's plan in mid-2010. FPL expects to provide a description of its approved plan for these DSM-based solar expenditures in its 2011 Site Plan.

3) <u>Supply Side Efforts – Power Purchases:</u>

FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy, and as-available energy, have been purchased by FPL from these types of facilities. (Please refer to Tables I.B.1, I.B.2, and Table I.C.1 in Chapter I).

Periodically, FPL invites renewables suppliers to provide proposals for renewable power and energy at or below avoided costs in response to FPL's Requests for Proposals (RFPs). FPL issued Renewable RFP's in 2007 and 2008 soliciting proposals to provide firm capacity and energy, and energy only, at or below avoided costs from renewable generators. FPL also promptly responds to inquiries for information from prospective renewable energy suppliers either by e-mail or phone.

With regard to existing contracts that have recently ended, FPL and the Solid Waste Authority of Palm Beach (SWA) agreed to extend their contract that expired March 31, 2010 for a 20 year term from April 1, 2012 through April 1, 2032. Also, the firm capacity and energy contract with Broward South that expired August 2009 was not renewed, but Broward South continues as an as-available supplier of energy to FPL

4) <u>Supply Side Efforts – FPL Facilities:</u>

FPL is in the process of developing a wind generation project on South Hutchinson Island in St. Lucie County. This project is known as the St. Lucie Wind project and it consists of up to six wind turbine generators capable of generating up to approximately 13.8 MW. In 2007, FPL began the St. Lucie County land use approval process, and soon after applied for the necessary federal and state permitting. However, a decision by the state and federal agencies on the St. Lucie Wind project's permitting will not be finalized until the local land use approval process is completed. The in-service date will depend on the approval and permitting process.

With regard to solar projects, FPL has completed construction of the nation's largest photovoltaic (PV) power generation facility in the country, the 25 MW DeSoto Next Generation Solar Energy Center. In addition, two solar projects that will add 85 MW of solar capacity are projected to be completed in 2010. These three projects are in response to the Florida Legislature's House Bill 7135 which was signed into law by Governor Crist in June 2008. House Bill 7135 (hereafter referred to as the 2008 Energy Bill), was enacted to enable the development of clean, zero greenhouse gas emitting renewable generation in the State of Florida. Specifically, the 2008 Energy Bill authorized cost recovery for the first 110 MW of eligible renewable projects that had the proper land, zoning and transmission rights in place. FPL's three solar projects met the specified criteria, and were granted approval for cost recovery in 2008. Each of the three solar projects is discussed below.

a. <u>The Martin Next Generation Solar Energy Center:</u>

This project will provide 75 MW of solar thermal capacity in an innovative way that directly displaces fossil fuel usage on the FPL system. This project will involve the installation of solar thermal technology that will be integrated into the existing steam cycle for the Martin Unit 8 natural gas-fired CC plant. This project will be the first "hybrid" solar plant in the world, the second largest solar facility in the world, and the largest solar plant of any kind in the U.S. outside of California. Construction began in December 2008 and is expected to be completed by the end of 2010.

b. **<u>The DeSoto Next Generation Solar Energy Center:</u>**

This facility has been constructed and began commercial operation in October 2009. It currently is providing up to 25 MW of PV non-firm capacity and energy, making it the largest PV facility in the U.S. The facility utilizes a tracking array that is designed to follow the sun as it traverses through the sky.

c. **<u>The Space Coast Next Generation Solar Energy Center:</u>**

Located at the Kennedy Space Center, this project is part of an innovative public/private partnership with NASA. When completed, it will provide up to 10 MW of PV non-firm capacity and energy. Construction began in June 2009 and is expected to be completed in 2010.

Each of these facilities is a significant and innovative renewable generating plant in its own right. Collectively, these Next Generation Solar Energy Centers are expected to produce a total of approximately 213,000 megawatt-hours (MWh) of electricity each year, and at peak production provide enough energy to serve the requirements of more than 15,000 homes.

For resource planning purposes, FPL projects that the energy delivered from these renewable facilities will be "as available", non-firm energy. This is due to several factors. First, the Martin solar thermal facility is designed as a "fuel-substitute" facility, not as a facility that will result in additional capacity and energy being generated. The solar thermal facility will displace the use of fossil fuel on the FPL system when the solar thermal facility is operating. Second, in regard to the two PV facilities, the intermittent nature of the solar resource makes it difficult to accurately determine what contribution the PV facilities at these specific locations can consistently make at FPL's late Summer afternoon and early Winter morning peak load hours. Once site-specific operating data has been gathered for an appropriate amount of time, FPL will then re-evaluate the actual output from each PV facility to determine what portion, if any, of its output can be projected as firm capacity at the projected peak hours in FPL's resource planning work.

In addition to these three approved projects, FPL is currently in the process of identifying other potential solar sites in the state in the event that a future Renewable Portfolio Standard (RPS), Clean Energy Portfolio Standard (CPS), or other enabling legislation is enacted by the Florida legislature. FPL is evaluating existing FPL generation sites along with potential greenfield sites within FPL's service territory. These potential FPL and greenfield sites are discussed further in Chapter IV.

5) **Ongoing Research & Development Efforts:**

FPL has developed alliances with several Florida universities to promote development of emerging technologies. For example, an alliance has been established with the newly formed Center for Ocean Energy Technology at Florida Atlantic University (FAU), which will focus on the commercialization of ocean current, ocean thermal (i.e., energy conversion as well as cold water air conditioning) and hydrogen technologies. FPL has been taking the lead in assisting FAU with the discussions being held with the U.S. Department of the Interior's Minerals Management Service Department (MMS). MMS is working to establish the permitting process for ocean energy development on the outer continental shelf.

FPL has also developed an alliance with the University of Florida to support its studies of biomass renewable potential and wind studies in the state. In addition, FPL has partnered with the Florida Institute of Technology on fuel cell technology and with the Florida State Universities Center for Applied Power System in regard to grid integration of ocean energy and other renewables.

FPL is also developing a "living lab" to demonstrate FPL's solar energy commitment to employees and visitors at its Juno Beach facility. FPL will evaluate multiple solar technologies and applications to develop a renewable business model resulting in the most cost-effective and reliable source(s) of solar energy to FPL customers.

FPL has also been in discussions with several private companies on multiple emerging technology initiatives including ocean current, ocean thermal, hydrogen, fuel cell technology, biomass, biofuels, and energy storage.

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. **FPL's Fuel Mix**

Until the mid-1980s, FPL relied primarily on a combination of fuel oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil–fired generation. In the early 1980s, FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit 4 which began serving FPL's customers in 1991. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP.

The trend since the early 1990s has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective CC generating units and the ready availability of natural gas. This planning document reflects an evolution in that trend in recognition that, although efficient gas-fired generation continues to provide significant benefits to FPL's customers, adding natural gas-fired additions exclusively would, in the long term, create an unbalanced generation portfolio. In 2009, FPL placed into commercial operation two new gas-fired CC units at the West County Energy Center (WCEC) site. A third new CC unit is projected to be added to the WCEC site in 2011. In addition, FPL is currently projecting to modernize its existing Cape Canaveral and Riviera plant sites by removing the existing steam generating units and replacing them with two highly efficient new CC units, one at each site. These new CC units will provide highly efficient generation that will dramatically improve FPL's overall system generation efficiency.

In addition, FPL is increasing its utilization of nuclear energy through capacity uprates of its four existing nuclear units. These uprates will add a total of approximately 400 MW of nuclear generation capacity by 2012. (FPL is also pursuing plans to obtain permits to build two new nuclear units at its existing Turkey Point site that, in total, would add approximately 2,200 MW of new nuclear generating capacity. FPL currently assumes, for resource planning purposes, that the in-service dates for the new nuclear units are outside of the 2010-2019 reporting time frame of this document. At the time this document is being prepared, FPL is evaluating what the revised in-service dates for Turkey Point Units 6 & 7 should be for planning purposes. FPL will address those revised in-service dates for planning purposes in its May 3, 2010 nuclear cost recovery filing to the FPSC.)

In regard to utilizing renewable energy, FPL has committed to add 110 MW of solar generating capacity by 2010 through a 75 MW solar thermal facility at FPL's existing Martin site, a 25 MW PV facility in DeSoto County, and a 10 MW PV facility in

Brevard County. The 25 MW PV facility was placed into commercial operation in 2009. The other two solar facilities are projected to be completed in 2010.

FPL's future resource planning work will continue to focus on identifying and evaluating alternatives that would most cost-effectively maintain and/or enhance FPL's long-term fuel diversity. These fuel diverse alternatives may include: the purchase of power from renewable energy facilities, addition of FPL-owned renewable energy facilities, obtaining access to diversified sources of natural gas such as liquefied natural gas (LNG) and natural gas from the Mid-Continent unconventional reserves, preserving FPL's ability to utilize fuel oil at its existing units, and increased utilization of nuclear energy. (New advanced technology coal generating units are not currently considered as viable options in Florida in the ten-year reporting period of this document due to concerns over greenhouse gas emissions.) The evaluation of the feasibility and cost-effectiveness of these, and other possible alternatives, will be an ongoing part of future planning cycles.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2019 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

2. **FPL's Fuel Mix**

Fossil fuel price forecasts, and the resulting projected price differentials between fuels, are major drivers used in evaluating alternatives for meeting future generating capacity needs. FPL's forecasts are generally consistent with other published contemporary forecasts.

Future oil and natural gas prices, and to a lesser extent, coal and petroleum coke prices, are inherently uncertain due to a significant number of unpredictable and uncontrollable drivers that influence the short-and long-term price of oil, natural gas, coal, and petroleum coke. These drivers include:

a. Current and projected worldwide demand for crude oil and petroleum products;

b. Current and projected worldwide refinery capacity/production;

c. Expected worldwide economic growth, in particular in China, and other Pacific Rim countries;

d. Organization of Petroleum Exporting Countries (OPEC) production, the availability of spare OPEC production capacity and the assumed growth in spare OPEC production capacity;

e. Non-OPEC production and expected growth in non-OPEC production;

f. The geopolitics of the Middle East, West Africa, the Former Soviet Union, Nigeria, Venezuela, etc., as well as, the uncertainty and impact upon worldwide energy consumption related to U. S. and worldwide environmental legislation, politics, etc.;

g. Current and projected North American natural gas demand;

h. Current and projected U.S., Canadian, and Mexican natural gas production;

i. The worldwide supply and demand for LNG; and

j. The growth in solid fuel generation on a U. S. and worldwide basis.

The inherent uncertainty and unpredictability in these factors today and tomorrow clearly underscores the need to develop a set of plausible oil, natural gas, and solid fuel (coal and petroleum coke) price scenarios that will bound a reasonable set of long-term price outcomes. In this light, FPL developed and utilized Low, Medium, and High price forecasts for fossil fuels in some of its 2009 resource planning work, particularly in regard to the nuclear cost recovery filings.

FPL's Medium price forecast methodology is consistent for oil and natural gas. For oil and natural gas commodity prices, FPL's Medium price forecast applies the following methodology:

a. For 2010 through 2012, the methodology used the January 26, 2010 forward curve for New York Harbor 1% sulfur heavy oil, U. S. Gulf Coast 1% sulfur heavy oil, ultra low sulfur diesel, and Henry Hub natural gas commodity prices;

b. For the next two years (2013 and 2014), FPL used a 50/50 blend of the January 26, 2010 forward curve and the most current projections at the time from The PIRA Energy Group;

c. For the 2015 through 2025 period, FPL used the annual projections from The PIRA Energy Group, and;

d. For the period beyond 2025, FPL used the real rate of escalation provided in the Energy Information Administration (EIA) *Annual Energy Outlook 2009* publication. FPL assumed a 2.5% annual rate of escalation to convert real prices to nominal prices prior to 2025, with no escalation from 2025 forward. In addition to the development of oil and natural gas commodity prices, nominal price forecasts also were prepared for oil and natural gas transportation costs. The addition of commodity and transportation forecasts resulted in delivered price forecasts.

FPL's Medium price forecast methodology is also consistent for coal and petroleum coke prices. Coal and petroleum coke prices were based upon the following approach:

a. The price forecasts for Central Appalachian coal (CAPP), Powder River Basin (PRB), South American coal, and petroleum coke were provided by JD Energy;

b. The marine transportation rates from the loading port for coal and petroleum coke to an import terminal were also provided by JD Energy;

c. The coal price forecast for SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements.

The development of FPL's Low and High price forecasts for oil, natural gas, coal, and petroleum coke prices were based on the historical volatility of the 12-month forward price, one year ahead. FPL developed these forecasts to account for the uncertainty which exists within each commodity as well as across commodities. These forecasts reflect a range of reasonable forecast outcomes.

3. <u>Nuclear Fuel Cost Forecast</u>

This section reviews the various steps needed to fabricate nuclear fuel for delivery to the nuclear power plants, the method used to forecast the price for each step, and other comments regarding FPL's nuclear fuel cost forecast.

a) <u>Steps Required for Nuclear Fuel to be delivered to FPL's Plants</u>

Four separate steps are required before nuclear fuel can be used in a commercial nuclear power reactor. These steps are summarized below.

(1) Mining: Uranium is produced in many countries such as Canada, Australia, Kazakhstan, and the United States. During the first step, uranium is mined from the ground using techniques such as open pit mining, underground mining, in-situ leaching operations, or production as a by-product from other mining operations, such as gold, copper, or phosphate rocks. The product from this first step is the raw uranium delivered as an oxide, U3O8 (sometimes referred to as yellowcake).

(2) Conversion: During the second step, the U3O8 is chemically converted into UF6 which, when heated, changes into a gaseous state. This second step further removes any chemical impurities and serves as preparation for the third step, which requires uranium to be in a gaseous state.

(3) Enrichment: The third step is called enrichment. Natural uranium contains 0.711% of uranium at an atomic mass of 235 (U-235) and 99.289% of uranium at an atomic mass of 238 (U-238). FPL's nuclear reactors use uranium with a higher percentage of up to five percent (5%) of U-235 atoms. Because natural uranium does not contain a sufficient amount of U-235, the third step increases the percentage amount of U-235 from 0.711% to a level specified when designing the reactor core (typically in a range from approximately 3% to as high as 5%). The output of this enrichment process is enriched uranium in the form of UF6.

(4) Fabrication: During the last step, fuel fabrication, the enriched UF6 is changed to a UO2 powder, pressed into pellets, and fed into tubes, which are sealed and bundled together into fuel assemblies. These fuel assemblies are then delivered to the plant site for insertion in a reactor.

Like other utilities, FPL has purchased raw uranium and the other components of the nuclear fuel cycle separately from numerous suppliers from different countries.

b) Price Forecasts for Each Step

(1) Mining: There is some volatility in the current uranium market. Demand is rather stable and outputs from production facilities have been increasing steadily. The following are the current major contributors that led to less volatility in the prices for uranium:

- The recent financial crisis had caused significant sales of inventories and caused the market price to drop earlier than predicted. However, Hedge funds continue to purchase uranium, reducing its availability to end users.

- The large inventory from the U.S. Department of Energy (DOE) is being withheld from the market due to political pressure from suppliers concerned about further price drop already affected by the current financial downturn. However, some of it is made available as barter in exchange for clean-up costs for the Department of Energy enrichment facilities.

- The Russians have announced that they would not supply down-blended weapons material to the U.S. government after 2013 for sale in the U.S. market. However, there is not an agreement between the U.S. and Russian government for the sales of enriched uranium.

- The U.S. Department of Commerce (DOC) has imposed restrictions on the import of nuclear fuel from France and Russia.

FPL expects the market to be more consistent with market fundamentals. In 2008 and 2009, a number of actions resolved restrictions of imports of foreign uranium. Recent law enacted in 2008 resolved the import of Russian-enriched uranium, by allowing some imports of Russian-enriched uranium to about 20-25% of needs for currently operating units, but with no restriction on the first core for new units and no restrictions after 2020. As mentioned earlier, the economic recession has also had a major impact and eliminated a significant portion of speculative demands with uranium pricing returning to close to the fundamentals. FPL cannot discount the possibility of future periodic sharp increase in prices, but believes such occurrences will likely be temporary in nature.

FPL's nuclear fuel price forecasts are the result of FPL's analysis based on inputs from various nuclear fuel market expert reports and studies.

(2) <u>Conversion:</u> FPL's price forecast considers the construction of new nuclear units. Just like for raw uranium, an increase in demand for conversion services would result from this need. Insufficient planned production is currently forecasted after 2013 to meet the higher demand scenario. As with additional raw uranium production, supply will expand beyond current level once more firm commitments are made including commitments to building new nuclear units.

(3) Enrichment: With no new production capacity, the current tight market supply for economically produced enrichment services will continue until 2013. The current expensive diffusion plant can make up any gaps in supply of enrichment services. In addition, there are a number of new facilities coming on-line through 2013, using more efficient and proven processes such as the use of centrifuges for enrichment of uranium. As with supply for the other steps of the nuclear fuel cycle, expansion of future capacity is feasible within the lead time for constructing new nuclear units and any other projected increase in demand. Meanwhile, world supply and demand will continue to be balanced such that FPL expects adequate supply of enrichment services. The tight supply/demand will most likely cause the price of enrichment services to continue to rise in the future.

(4) Fabrication: Because the nuclear fuel fabrication process is highly regulated by the Nuclear Regulatory Commission (NRC), not all production facilities can qualify as suppliers to nuclear reactors in the U.S. Although world supply and demand is expected to show significant excess capacity for the foreseeable future, the gap is not as wide for U.S. supply and demand. The supply for the U.S. market is expected to be sufficient to meet U.S. demand for the foreseeable future.

c) Other Comments Regarding FPL's Nuclear Fuel Cost Forecast

The calculations for the nuclear fuel cost forecasts used in FPL's 2009 resource planning work were performed consistent with the method then used for FPL's Fuel Clause filings, including the assumption of a fuel lease and the assumption of refueling outages every 18 months. The costs for each step to fabricate the nuclear fuels were added to come up with the total costs of the fresh fuel to be loaded at each refueling (acquisition costs). The acquisition cost for each group of fresh fuel assemblies were then amortized over the energy produced by each group of fuel assemblies FPL also added 1 mill per kilowatt hour net to reflect payment to DOE for spent fuel disposal.[3]

[3] Consistent with the FPSC's decision in FPL's recent base rate case, FPL will no longer be leasing its nuclear fuel. This fact, and its implications on the projected costs of nuclear fuel, will be reflected in FPL's 2010 and later resource planning work.

Schedule 5
Fuel Requirements 1/

	Fuel Requirements	Units	Actual 2/		Forecasted									
			2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
(1)	Nuclear	Trillion BTU	261	250	267	249	260	304	309	305	305	309	305	304

								2012 Changes/Additions with Inactive Reserve Total:				658	298	

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All MW additions/changes occurring later in the year will be picked up for reporting/planning purposes in the following year.

Note 2. Changes shown may include different ratings than shown in Schedule 1 due solely to ambient temperature consistent with those in FPL 's peak load forecast to maintain consistency in reserve margin calculations.

Note 3. The Martin solar thermal facility is designed to provide steam for FPL's existing Martin Unit 8 combined cycle unit, thus reducing FPL's use of natural gas. No additional capacity (MW) will result from the operation of the solar thermal facility.

Note 4: The Photovoltaic MWs are not included in the total at this time because these facilities are assumed to provide non-firm energy only.

Note 5: The nuclear uprates will be performed during the scheduled refueling outages for each unit.

Note 6: Certain existing FPL units that have been placed temporarily on inactive Reserve status are assumed, for planning purposes, to return to active reserve starting in 2016.

2019 Changes/Additions with Inactive Reserve Total:												394	387	

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All MW additions/changes occuring later in the year will be picked up for reporting/planning purposes in the following year.

Note 2: Changes shown may include different ratings than shown in Schedule 1 due solely to ambient temperature consistent with those in FPL 's peak load forecast to maintain consistency in reserve margin calculations.

Note 3: The nuclear uprates will be performed during the scheduled refueling outages for each unit.

Note 4: Certain existing FPL units that have been placed temporarily on Inactive Reserve status are assumed, for planning purposes,to return to active reserve starting in 2018

Schedule 9

Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Space Coast Next Generation Energy Center

(2) **Capacity**
a. Summer 10 MW
b. Winter 10 MW

(3) **Technology Type:** Photovoltaic

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2009
b. Commercial In-service date: 2010

(5) **Fuel**
a. Primary Fuel Solar
b. Alternate Fuel N/A

(6) **Air Pollution and Control Strategy:** N/A

(7) **Cooling Method:** N/A

(8) **Total Site Area:** 60 Acres

(9) **Construction Status:** U (Under Construction)

(10) **Certification Status:** Permitted (Individual Permits)

(11) **Status with Federal Agencies:** Permitted

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	N/A
Forced Outage Factor (FOF):	N/A
Equivalent Availability Factor (EAF):	0.98
Resulting Capacity Factor (%):	Approx. 21.3% (First Full Year of Operation)
Average Net Operating Heat Rate (ANOHR):	N/A Btu/kWh
Base Operation 75F,100%	

(13) **Projected Unit Financial Data *,****

Book Life (Years):	25 years
Total Installed Cost (2010 $/kW):	7,890
Direct Construction Cost ($/kW):	-
CWIP Amount ($/kW):	427.7
Escalation ($/kW):	-
Fixed O&M ($/kW -Yr.): (2010 $kW-Yr)	54
Variable O&M ($/MWH): (2010 $/MWH)	0
K Factor:	1.2100

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement.

NOTE: Total installed cost includes transmission interconnection.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1)	**Plant Name and Unit Number:**	West County Energy Center Combined Cycle Unit 3	
(2)	**Capacity**		
	a. Summer	1,219 MW	
	b. Winter	1,335 MW	
(3)	**Technology Type:**	Combined Cycle	
(4)	**Anticipated Construction Timing**		
	a. Field construction start-date:	2009	
	b. Commercial In-service date:	2011	
(5)	**Fuel**		
	a. Primary Fuel		Natural Gas
	b. Alternate Fuel		Distillate
(6)	**Air Pollution and Control Strategy:**		Natural Gas, Dry Low No_x Combustors, SCR 0.0015% S. Distillate, & Water Injection on Distillate
(7)	**Cooling Method:**		Cooling Tower
(8)	**Total Site Area:**	220	Acres
(9)	**Construction Status:**	U	(Under construction, less than or equal to 50% Complete)
(10)	**Certification Status:**	Permitted	
(11)	**Status with Federal Agencies:**	Permitted	

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 93%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582	Btu/kWh (Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data **,*****

Book Life (Years):	25	years
Total Installed Cost (2011 $/kW):	709	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):	71	
Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2011 $kW-Yr)	11.63	
Variable O&M ($/MWH): (2011 $/MWH)	0.480	
K Factor:	1.4697	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** St. Lucie 1 Nuclear (Uprate)

(2) **Capacity**
a. Summer 103 MW (Incremental)
b. Winter 103 MW (Incremental)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2011

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel —

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	No change from existing unit
Forced Outage Factor (FOF):	No change from existing unit
Equivalent Availability Factor (EAF):	No change from existing unit
Resulting Capacity Factor (%):	No change from existing unit
Average Net Operating Heat Rate (ANOHR):	No change from existing unit
Base Operation 75F,100%	No change from existing unit

(13) **Projected Unit Financial Data** *

Book Life (Years):	25	years (Matches the current operating license period.)
Total Installed Cost ($/kW): **	TBD	(See Note (1) for explanation.)
Direct Construction Cost:	TBD	(See Note (1) for explanation.)
AFUDC Amount ($/kW):		(See Note (2) for explanation.)
Escalation ($/kW):		(See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.):	There is no additional O&M impact from this project.	
Variable O&M ($/MWH):	There is no additional O&M impact from this project.	
K Factor:		(See Note (2) for explanation.)

NOTE:
(1) The projected capital cost values for the capacity uprates at each of FPL's existing nuclear units is currently being reviewed in on-going analyses as this document is being prepared. The capital cost projections that will result from these analyses are expected to be presented in FPL's May 2010 Nuclear Cost recovery filing.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

* $/kW values are based on incremental Summer capacity.
** $/incremental kW

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:**		Turkey Point 3 Nuclear (Uprate)	
(2) **Capacity**			
a. Summer	104	MW (Incremental)	
b. Winter	104	MW (Incremental)	
(3) **Technology Type:**	Nuclear		
(4) **Anticipated Construction Timing**			
a. Field construction start-date:		During scheduled refueling outage	
b. Commercial In-service date:		2012	
(5) **Fuel**			
a. Primary Fuel		Uranium	
b. Alternate Fuel		---	
(6) **Air Pollution and Control Strategy:**		No change from existing unit	
(7) **Cooling Method:**		No change from existing unit	
(8) **Total Site Area:**		No change from existing unit	
(9) **Construction Status:**	T	(Regulatory approval received, but not under construction)	
(10) **Certification Status:**	T	(Regulatory approval received, but not under construction)

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Space Center Next Generation Solar Energy Center (PV)

The new Space Center Next Generation Solar Energy Center (PV) does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

West County Energy Center Unit 3

(1)	Point of Origin and Termination:	New Sugar Substation – Corbett Substation
(2)	Number of Lines:	1
(3)	Right-of-way	FPL - Owned
(4)	Line Length:	1 mile
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: May 2009 End date: November 2010
(7)	Anticipated Capital Investment: (Trans. and Sub.)	$11,300,000
(8)	Substations:	New Sugar Substation and Corbett Substation
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

St. Lucie 1 Nuclear (Uprate)

The St. Lucie 1 Nuclear (Uprate) does not require any “new” transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point 3 Nuclear (Uprate)

The Turkey Point 3 Nuclear (Uprate) does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

St. Lucie 2 Nuclear (Uprate)

The St. Lucie 2 Nuclear (Uprate) does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point 4 Nuclear (Uprate)

The Turkey Point 4 Nuclear (Uprate) does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Cape Canaveral Next Generation Clean Energy Center (Projected Modernization)

The Cape Canaveral Next Generation Clean Energy Center, that would be the result of the projected modernization of the exiting Cape Canaveral power plant site, does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Riviera Beach Next Generation Clean Energy Center (Projected Modernization)

The Riviera Beach Energy Center Modernization, that would be the result of the projected *modernization of the existing* Riviera Beach power plant site, does not require any "new" transmission lines. Several lines will be extended and reconfigured to accommodate the increased capacity.

Schedule 11.1

Existing FIRM and NON-FIRM Capacity and Energy by Primary Fuel Type
Actuals for the Year 2009

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
		Net (MW) Capability				NEL	Fuel Mix
	Generation by Primary Fuel	Summer (MW)	Summer (%)	Winter (MW)	Winter (%)	GWh [2]	%
(1)	Coal	900	3.3%	902	3.2%	6,362	5.7%
(2)	Nuclear	2,939	10.9%	3,013	10.6%	22,893	20.6%
(3)	Residual	6,764	25.0%	6,818	23.9%	4,560	4.1%
(4)	Distillate	1,908	7.1%	2,160	7.6%	21	0.0%
(5)	Natural Gas	11,993	44.4%	12,942	45.3%	62,728	56.4%
(6)	*FPL Existing Units Total [1]:*	*24,504*	*90.7%*	*25,835*	*90.5%*	*96,565*	*86.8%*
(7)	Renewables (Purchases)- Firm	111.0	0.4%	162.0	0.6%	1,036	0.9%
(8)	Renewables (Purchases)- Non-Firm	Not Applicable		Not Applicable		416	0.4%
(9)	*Renewable Total:*	*111.0*	*0.4%*	*162.0*	*0.6%*	*1,452*	*1.30%*
(10)	*Purchases Other :*	*2,404.0*	*8.9%*	*2,542.0*	*8.9%*	*13,288*	*11.9%*
(11)	*Total :*	*27,019.4*	*100.0%*	*28,539.0*	*100.0%*	*111,304*	*100.0%*

Note:
(1) FPL Existing Units Total should match Total System found on Schedule 1 for summer and winter.
(2) Net Energy for Load GWH should match Schedule 6.1 the actual value.

Schedule 11.2

Existing NON-FIRM Self-Service Renewable Generation Facilities
Actuals for the Year 2009

(1) Type of Facility	(2) Installed Capacity DC (MW)	(3) Renewable Projected Annual Output (MWh)	(4) Annual Energy Purchased from FPL (MWh)	(5) Annual Energy Sold to FPL (MWh)	(6) = (3+4) - (5) Projected Annual Energy Used by Customer (MWh)
Customer-Owned PV (0 kW to 10 kW)	2.525	2,095	42,634.0	30.0	44,698.9
Customer-Owned PV (> 10 kW to 100 kW)	1.085	865	12,938	54.0	13,749.1
Customer-Owned PV (> 100 kW - 2 MW)	2.846	379	29,739	0.0	30,118.5
Total	6.456	3,339.1	85,311.3	84.0	88,566.5

Notes:

(1) There were approximately 645 customer-owned operating PV facilities interconnected with FPL during 2009.
(2) The Installed Capacity value is the sum of the nameplate ratings (DC MW) for all of the customer-owned PV facilities connected as of Dec. 31,2009.
(3) The Projected Annual Output value is based on NREL's PV Watts program and the Installed Capacity value in column (2), adjusted for the date when each facility was installed and assuming each facility operated as planned.
(3) The Annual Energy Purchased from FPL is an actual value from FPL's metered data for 2009.
(4) The Annual Energy Sold to FPL is an actual value from FPL's metered data for 2009.
(5) *The Projected Annual Energy Used by Customers* is a projected value that equals:
(Renewable Projected Annual output + Annual Energy Purchased) minus the Annual Energy Sold to FPL.

(This page is left intentionally blank.)

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered or threatened plant and animal species. FPL competes for air, land, and water resources that are necessary to meet the demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among electric utilities for its commitment to the environment. For example, FPL has one of the lowest CO_2 emission rates in the nation. The environmental leadership of FPL and its parent company, FPL Group, has been heralded by many outside organizations as demonstrated by a few recent examples. In 2009, FPL Group was ranked first among electric and gas utilities in FORTUNE® magazine's, "America's Most Admired Companies" edition. This is the third consecutive year that FPL Group scored number one in each of the eight attributes considered: innovation, people management, use of corporate assets, social responsibility, quality of management, financial soundness, long-term investments, and quality of products and services. According to *Fortune*, America's Most Admired Companies is "the definitive report card on corporate reputations".

FPL Group was named, for the fifth time, one of the Global 100 Most Sustainable Corporations in the World by Corporate Knights, Inc., a Canadian media company. Some 1,800 companies from a wide range of sectors were evaluated regarding effective management of environmental, social, and governance risks and opportunities. FPL Group was one of only three United States utility companies, or utility parent companies, to make the list of 100.

FPL Group's commitment to acknowledging the risks of climate change and effectively reducing its greenhouse gas emissions was again recognized when the company was named to the Carbon Disclosure Leadership Index for 2009. FPL Group was one of only three U.S. companies to be so named. The Carbon Disclosure Leadership Index is produced annually by the Carbon Disclosure Project (CDP), a not-for-profit organization that reports on the business risks and opportunities of climate change for investors. CDP represents 475 institutional investors with $55 trillion in assets under management. Compiled by PricewaterhouseCoopers on behalf of CDP, the Carbon Disclosure Leadership Index highlights companies within the S&P 500 Index that excel in the area of climate change awareness and action.

FPL Group was named to the 2009 Dow Jones Sustainability Index (DJSI) of the leading companies in North America for corporate sustainability. The DJSI North America selects the top 20 percent of companies in sustainability performance from the 600 largest companies in North America. According to Dow Jones, corporate sustainability leaders achieve long-term shareholder value by "gearing their strategies and management to harness the market's potential for sustainability products and services while successfully reducing and avoiding sustainability costs and risks."

The 11th Annual Sustainable Florida Best Practice Awards were announced on June 9, 2009 in Orlando, Florida. FPL was named a finalist in the large business category for its "initiative and leadership in the voluntary development of three state-of-the-art clean, renewable, emissions-free solar energy facilities." The awards are presented by the Council for Sustainable Florida, the premier statewide organization committed to balancing the economic interests of the state with the need to be socially and environmentally responsible. The Sustainable Florida Award recognizes organizations for protecting and preserving Florida's environment for the future while building markets for Florida's business.

In 2009, FPL received the Business of the Year Award from Martin County for efforts related to the construction of three solar energy facilities in Florida, including one in Martin County.

In recognition of the company's leadership role in using low-carbon vehicles, FPL earned the 2008 National Biodiesel Board's Eye on Innovation award for the early and substantive use of biodiesel, the 2008 National Association of Fleet Administrator's Green Fleet Award, and the 2007 Council for Sustainable Florida Large Business Best Practice Award.

In May 2007, FPL Group was included on the KLD Global Climate 100SM Index for the third time since the Global Climate 100 was launched in 2005. The Global Climate 100 is designed to promote investment in public companies whose activities demonstrate the greatest potential for reducing the social and economic consequences of climate change.

The Global Climate 100 Index includes a mix of 100 global companies that demonstrate leadership in providing near-term solutions to climate change through renewable energy, alternative fuels, clean technology, and efficiency.

In 2006, FPL and the Palm Beach County-based Arthur R. Marshall Foundation joined as "partners for the environment." FPL's support included a $25,000 donation to the non-profit organization for educational and restoration programs, including the planting of native Florida wetland trees. In 2007, FPL volunteers returned to the site of the tree plantings to help take care of the growing saplings.

FPL has also been the recipient of earlier environmental awards and recognition. In 2001, FPL was awarded Edison Electric Institute's National Land Management Award for its stewardship of 25,000 acres surrounding its Turkey Point Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. FPL received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" in 2001 for its emission-reducing "repowering" projects at its Fort Myers and Sanford Plants. FPL won the Council for Sustainable Florida's award in 2002 for its sea turtle conservation and education programs at its St. Lucie Plant. Finally, FPL has been recognized by numerous federal and state agencies for its innovative endangered species protection programs which include such species as manatees, crocodiles, and sea turtles.

As mentioned above, FPL Group has taken a leadership role to address climate change and the call for action for a national climate change policy. The decision to step into the forefront of this issue goes hand-in-hand with FPL Group's longtime commitment to managing operations with sensitivity to the environment.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Commitment in 1992 to clearly define its position. This statement reflects how FPL incorporates environmental values into all aspects of its activities and serves as a framework for new environmental initiatives throughout the company. FPL's Environmental Statement is:

It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:

- Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
- Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
- Encourage the wise use of energy to minimize the impact on the environment.
- Communicate effectively on environmental issues.
- Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, a dedicated environmental corporate governance program, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident and/or emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with corporate policy as well as legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and FPL policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2009 environmental outreach activities are noted in Table IV.E.1. In 2009 and 2010, FPL launched web cams at three facilities in order to increase public awareness of ongoing solar projects and the warm water refuge for manatees provided by power plants. The "solar cams" provide the public with a glimpse of the PV installation at the Space Coast Next Generation Solar Energy Center and the solar thermal installation at the Martin Next Generation Solar Energy Center. Additionally, the "manatee cam" provides the public a glimpse of hundreds of manatees that gather in the warm waters near the FPL Riviera Plant each Winter during the cold weather. In the first two months the manatee cam has been operational, the cam has received over 78,000 page views on-line. These web cam addresses, respectively, are:

http://www.fpl.com/environment/solar/spacecoast_cam.shtml),
(http://www.fpl.com/environment/solar/martin_cam.shtml),
http://www.fpl.com/environment/plant/riviera_cam.shtml).

In 2009 FPL also initiated efforts to recommence tours of the Barley Barber Swamp at the Martin Power Plant. Public tours are expected to begin by the end of 2010.

Table IV.E.1: 2009 FPL Environmental Outreach Activities

Activity	# of Participants (Approx.)
Visitors to FPL's Energy Encounter at St. Lucie	20,000
Visitors to Manatee Park	180,000
Number of visits to FPL's Environmental Website	103,000
Number of pieces of Environmental literature distributed	>60,000
Solar Schools Program (# of schools participating)	13

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified seven Preferred Sites and ten Potential Sites for future generation additions. Preferred Sites are those locations where FPL has conducted significant reviews and has either taken action, or is currently committed to take action, to site new generation capacity. Potential Sites are those sites that have attributes that support the siting of generation and are under consideration as a location for future generation. Some of these sites are currently in use as existing generation sites and some are not. The identification of a Potential Site does not indicate that FPL has made a definitive decision to pursue generation (or generation expansion in the case of an existing generation site) at that location, nor does this designation indicate that the size or technology of a generator has been determined. The Preferred Sites and Potential Sites are discussed in separate sections below.

As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites and other Greenfield sites.

IV.F.1 Preferred Sites

FPL identifies seven Preferred Sites in this Site Plan: the West County Energy Center (WCEC) adjacent to the existing Corbett FPL substation, the existing St. Lucie plant site, the existing Turkey Point plant site, the existing Cape Canaveral plant site, the existing Riviera plant site, and two locations for new solar power generation: Brevard County and the existing Martin plant site.

The West County Energy Center site is the location for one CC capacity addition FPL will make in 2011. The St. Lucie site is the location for nuclear capacity uprates that FPL will make in 2011 and 2012. The St. Lucie site is also the location for a proposed wind generation addition. The Turkey Point site is the location for nuclear capacity uprates that FPL will make in 2011 and 2012. (Turkey Point is also the site for two new nuclear units, Turkey Point Units 6 & 7, for which FPL is pursuing licensing approvals. Current projections for these new, nuclear units' in-service dates are beyond the 2010-2019 reporting time frame of this document.). The Cape Canaveral and Riviera sites are the locations for potential modernizations of existing power plant sites that are projected in this document. And, as previously mentioned, the other two sites, Brevard County and Martin County, are the sites for new solar energy facilities.

The seven Preferred Sites are discussed below.

Preferred Site # 1: West County Energy Center, Palm Beach County

FPL has identified the property adjacent to the existing Corbett Substation property in unincorporated western Palm Beach County as a Preferred Site for the addition of new generating capacity. The site was selected for the addition of another CC natural gas unit (Unit 3) with ultra-low sulfur light fuel oil (distillate) as a backup fuel. WCEC Units 1 & 2 were constructed on this site and went into commercial operations on August 27, 2009, and November 3, 2009, respectively. WCEC Unit 3, which began construction in March 2009, was approved by both the FPSC and the Secretary of the Florida Department of Environmental Protection (FDEP) and is anticipated to go into commercial operation in June of 2011. Unit 3 will be identical to Units 1 & 2 in regard to technology and capacity.

The existing site is accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections. The facility will use natural gas as the primary fuel and state-of-the-art combustion controls.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the West County Energy Center (WCEC) plant site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the WCEC generating facilities at the site is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

The site was undeveloped until February 2007 when construction of WCEC Units 1 & 2 was initiated. The site was previously dedicated to industrial (mining) and agricultural use. The site had been excavated, back-filled, and totally re-graded to an elevation of approximately 10 feet above the surrounding land surface. Prior to the initiation of power plant construction, no structures were present on the site and vegetation was virtually non-existent. Units 1 & 2 are completed and are now in commercial operation.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The plant site had been significantly altered by the construction and operation of a limestone mine where vegetation had been cleared and removed. The surrounding land use is predominantly sugar cane, agriculture, and limestone mining. FPL's existing Corbett substation is located north of the site. The Arthur R. Marshall Loxahatchee National Wildlife Refuge is located to the south of the site.

2. Listed Species

Construction and operation of Unit 3 at the site will not affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the prior mining activities. Common wading birds can be observed on areas adjacent to, and occasionally within, the property. The property is adjacent to areas that have been identified as potential habitats for wood stork.

3. Natural Resources of Regional Significance Status

The construction and operation of another gas-fired CC generating facility at this location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands including the Arthur R. Marshall Loxahatchee National Wildlife Refuge. Construction will not result in any onsite wetland impacts under federal, state, or local agency permitting criteria.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design of Unit 3 comprises the following: one 1,219 MW (Summer capacity) unit consisting of: three combustion turbines (CT), three heat recovery steam generators (HRSG), and a new steam turbine. Natural gas delivered via pipeline is the primary fuel type for this facility with ultra-low sulfur light fuel oil (distillate) serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the project site is "Rural Residential" according to the Palm Beach County Future Land Use Map. Designations for the area under the Palm Beach County Unified Land Development Code classified the project site and surrounding area as Special Agricultural District. The site has been granted conditional use for electrical power facilities under a General Industrial zoning district.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues.

i. **Water Resources**

WCEC Units 1 & 2 are currently operating using water from the Floridan Aquifer for cooling, service, and process water. Potable water is purchased from the Palm Beach County water municipality.

The primary water source for the entire site will be reclaimed (reuse) water that will come from Palm Beach County Water Utilities Department once Unit 3 is complete. FPL has obtained the necessary approvals to also supply WCEC Units 1 & 2 using reclaimed water once WCEC Unit 3 is operational. Reclaimed water will be used for cooling, service, and process water. Backup water sources include utilizing the Floridan Aquifer allocation permitted for WCEC Units 1, 2, & 3.

j. **Geological Features of Site and Adjacent Areas**

The site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks. Little information is known about these rocks due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, clay, and phosphate grains. The deepest formation in Palm Beach County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying

Oldsmar formation. The published information on the sediments comprising the formations below the Avon Park Limestone is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach counties.

Testing during construction of Exploratory Well 2 (EW-2) demonstrated the presence of a highly permeable zone (Boulder Zone) below a depth of 2,790 feet below pad level (bpl) overlain by a thick confining interval from approximately 2,000 to 2,790 feet bpl. The base of the Underground Source of Drinking Water (USDW) was identified between the depths of 1,932 and 1,959 feet bpl through interpretation of packer tests, water quality data, and geophysical logs. Injection testing has confirmed that the hydrogeology of the EW-2 site is favorable for disposal of fluids via a deep injection well system.

k. <u>Projected Water Quantities for Various Uses</u>

The estimated quantity of water required for industrial processing and cooling for all 3 units is approximately 29 million gallons per day (mgd). Cooling water for the three generating units would be cycled through cooling towers. Water quantities needed for other uses such as potable water are estimated to be approximately 35,000 gallons per day (gpd) for the entire WCEC site.

l. <u>Water Supply Sources by Type</u>

WCEC Units 1 & 2 will use available ground water as the source of cooling water until Unit 3 comes on line. Cooling towers will act as a heat sink for the facility auxiliary cooling system. Such needs for cooling and process water will comply with the existing SFWMD regulations for consumptive water use.

WCEC Unit 3, and eventually Units 1 & 2, will use reclaimed water as the primary source of cooling water for the cooling tower. The cooling tower will also act as a heat sink for the facility auxiliary cooling system. Such needs for cooling and process water will comply with the existing SFWMD regulations for consumptive water use. In addition, reclaimed water used at WCEC must meet all relevant requirements of Chapter 62-610, F.A.C., Part III, for use in cooling towers.

m. <u>Water Conservation Strategies Under Consideration</u>

The use of reclaimed water is a water conservation strategy because it is a beneficial use of wastewater. Impacts on the surficial aquifer would be minimized and used only for potable water, if necessary. Water from the Floridan Aquifer will be used for cooling purposes as a backup water source and cooling towers will be utilized. In addition, captured stormwater may be reused in the cooling tower whenever feasible. Stormwater captured in the stormwater ponds will also recharge the surficial aquifer.

n. Water Discharges and Pollution Control

Heat will be dissipated in the cooling towers. Blowdown water from the cooling towers, along with other wastestreams, will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. In addition, captured stormwater may be reused in the cooling towers, whenever feasible. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is serviced by a new natural gas transmission pipeline that is capable of providing a sufficient quantity of gas to the entire site. Ultra-low sulfur light fuel oil (distillate) will be received by truck and stored in above-ground storage tanks to serve as backup fuel for the WCEC generating units.

p. Air Emissions and Control Systems

The use of natural gas and ultra-low sulfur light fuel oil (distillate) and combustion controls will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminants. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil (distillate) as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the WCEC generating units incorporate features that will make them among the most efficient and cleanest power plants in the State of Florida.

q. **Noise Emissions and Control Systems**

Noise expected to be caused by construction at the site is expected to be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will be within allowable levels.

r. **Status of Applications**

In regard to WCEC Unit 3, a Site Certification Application (SCA) was filed in December 2007 and received Site Certification by the Secretary of the FDEP, in lieu of the Governor and Cabinet, in November 2008. A Prevention of Significant Deterioration (PSD) air permit was filed in December 2007. The permit was issued by FDEP in July 2008. FPL initiated construction in March 2009 and anticipates an in-service date of mid-2011. WCEC Unit 3 will utilize the underground injection control (UIC) system permitted for the entire site.

Preferred Site # 2: St. Lucie Plant, St. Lucie County

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The plant site is bordered by the Atlantic Ocean to the east and the Indian River Lagoon to the west. Located on the site are two nuclear-powered generating units, St. Lucie Units 1 & 2, which have been in operation since 1976 and 1983, respectively. The St. Lucie site has been selected as a Preferred Site for the addition of two types of new generating capacity.

The first type of generating capacity addition is an increase in the capacity of the two existing nuclear generating units that is used to serve FPL's customers of approximately 103 MW for St. Lucie Unit 1 and 88 MW for St. Lucie Unit 2. This difference is due to FPL's 100% ownership share of St. Lucie 1 and its 85% ownership share of St. Lucie Unit 2. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing Turkey Point nuclear units, was approved by the FPSC in January 2008. The capacity uprates at St. Lucie for the two nuclear units sited there are projected to be in-service in late 2011 and 2012.

The second type of generating capacity addition is the proposed installation of FPL wind generation turbines at the plant site. In 2007, FPL began the St. Lucie County land use approval process, and soon after applied for the necessary federal and state permitting. However, a decision by the state and federal agencies on the St. Lucie Wind project's permitting won't be finalized until the local land use approval process is completed. The in-service date will depend on the approval and permitting process. Six wind turbines are being proposed that, in total, would have a maximum output of approximately 13.8 MW.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the FPL St. Lucie Nuclear site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the proposed generating facilities at the site is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

St. Lucie Units 1 & 2 are pressurized water reactors, each having two steam generators. The prominent structures, enclosed facilities, and equipment associated with St. Lucie Units 1 & 2 include the containment building, the turbine generator building, the auxiliary building, and the fuel handling building.

Prominent features beyond the power block area include the intake and discharge canals, switchyard, spent-fuel storage facilities, technical and administrative support facilities, and public education facilities (the Energy Encounter and the College of Turtle Knowledge). Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay, and Indian River Lagoon.

In regard to the nuclear capacity uprates, the only changes will be modifications to the existing power generation facilities within the power block area, modifications to the switchyard facilities, and modifications to the transmission lines from St. Lucie to Midway substation. None of the other existing facilities at the plant will change as a result of the uprates. No changes to the nuclear power generation facilities are projected as a result of the proposed wind turbine additions.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The St. Lucie Plant includes the reactor buildings, turbine buildings, access/security building, auxiliary building, maintenance facilities, and miscellaneous warehouses and other buildings associated with the operation of Units 1 & 2. The site includes adjacent undeveloped mangrove areas. As a result of the approved capacity uprates, the site characteristics will not change.

The proposed wind turbines would also be located on the FPL-owned site. Impacts to the site characteristics are projected to be minimal from the proposed wind turbines.

2. Listed Species

Some listed species known to occur in the area of the plant location are Atlantic sturgeon, smalltooth sawfish, loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas)*, leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtle (*Eretmochelys imbriccata*), gopher tortoise (*Gopherus polyphemus*), kemp's ridley sea turtle (*Lepidochelys kempi*), wood stork (*Mycteria americana*), black skimmer (*Rynchops niger*), and least tern (*Sterna antillarum*).

In regard to the nuclear capacity uprates, neither the development work, nor the continued operation of the two nuclear units after the uprate work has been completed, are expected to adversely affect any rare, endangered, or threatened species. No changes in wildlife populations at the adjacent undeveloped areas are anticipated, including listed species. Noise and lighting impacts will not change and it is expected that wildlife will continue to use the undeveloped areas within the St. Lucie Plant boundary.

In regard to the wind turbines, some changes to the adjacent undeveloped areas are anticipated. Noise and lighting impacts will not change and the wind turbines are not anticipated to deter the continued use by wildlife of the undeveloped areas within the St. Lucie Plant boundary or any adjacent areas.

3. **Natural Resources of Regional Significance Status**

Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay, and Indian River Lagoon.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. It is a once-through system. The effects of the discharge of cooling water via these discharge structures were evaluated and mixing zones were established to allow compliance with thermal water quality standards as a part of the Plant's NPDES (Permit No. FL0002208). These mixing zones include the volume of water beyond the discharge structures, at the edge of which the water temperature is no greater than 17°F above the ambient temperature of the intake water.

In regard to the nuclear capacity uprates, the once-through system will continue to be used for the nuclear units. In regard to the wind turbines, no water will be required.

g. **Local Government Future Land Use Designations**

St. Lucie Units 1 & 2 are located in unincorporated St. Lucie County, Florida. The County has adopted a comprehensive plan, which is updated on a periodic basis. The County Comprehensive Plan incorporates a map that depicts the future land use categories of all property falling within the unincorporated portions of the County. The St. Lucie Plant has a Future Land Use category of Transportation/Utilities (T/U) according to the St. Lucie County Future Land Use Map. The T/U category is described in the St. Lucie County Comprehensive Plan Future Land Use Element Future Land Use.

In regard to the wind turbines, FPL has submitted an application to St. Lucie County to rezone the land that would serve as the footprint of the turbines to the T/U category.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity. The site has been selected as a Preferred Site for the wind turbines because of the available wind resource at that location.

i. **Water Resources**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. The once-through system flow will not change as a result of the nuclear uprates. No water will be required to operate the wind turbines. Due to the existing nature of the St. Lucie Plant, surrounding surface waters will not be adversely affected by either of the generation capacity additions. Stormwater will be handled by the existing facilities and no new areas will be impacted. Wetlands, groundwater, and nearby surface waters will not be impacted.

j. **Geological Features of Site and Adjacent Areas**

Beneath the land surface, there is a peat layer 4 to 6 feet thick. Below this layer is the Anastasia Formation, a sedimentary rock formation composed of clay lenses, sandy limestone, and silty fine to medium sand with fragmented shells. This highly permeable stratum extends 35 to 90 feet below mean sea level (msl). Underlying this stratum there is a semi-permeable zone, The Hawthorn Formation, consisting of slightly clayey and very fine silt which extends 600 feet below msl.

The original surficial deposits at the St. Lucie Plant were excavated to a depth of 60 feet and backfilled with Category I or II fill. The fill is underlain by the Anastasia formation, a sequence of partially cemented sand and sandy limestone, which extend to an average depth of about 145 feet. The Anastasia is underlain to a depth of about 600 to 700 feet by the partially cemented and indurated sands, clays, and sandy limestones of The Hawthorn Formation. Underlying these surface strata are about 13,000 feet of Jurassic through Tertiary Formations, primarily carbonate rocks. These formations have a relatively gentle slope to the southeast.

k. **Projected Water Quantities for Various Uses**

In regard to the nuclear capacity uprates, no change is expected in the quantity or characteristics of industrial wastewaters generated by the facility. Therefore, no change in that compliance achievement status is expected. The capacity uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The St. Lucie Plant does not directly withdraw groundwater under its current operations and it will not withdraw groundwater after the capacity uprates work is completed. The use of water supplied by the City of Fort Pierce, which does withdraw groundwater, will remain unchanged and there will be no changes to the groundwater discharges. There will be no quality, quantity, or hydrological changes, either by withdrawal or discharge to a drinking water source. Therefore, there will be no impacts on drinking water.

The wind turbines will not require water for operations and will not cause any changes in the hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow.

l. **Water Supply Sources by Type**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. General plant service water, fire protection water, process water, and potable water are obtained from City of Fort Pierce. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns.

The existing St. Lucie Plant water use is projected to be unchanged as a result of the nuclear capacity uprates. The wind turbines will not require water for operations.

m. **Water Conservation Strategies Under Consideration**

The existing water resources will not change as a result of the nuclear capacity uprates. The wind turbines will not require water for operations.

n. **Water Discharges and Pollution Control**

St. Lucie Units 1 & 2 use once-through cooling water from the Atlantic Ocean to remove heat from the main (turbine) condensers via the Circulating Water System (CWS), and to remove heat from other auxiliary equipment via the Auxiliary Equipment Cooling Water System (AECWS). The great majority of this cooling water is used for the CWS.

Under emergency conditions, water can be withdrawn from Big Mud Creek via the Emergency Intake Canal through two 54-inch pipe assemblies in the barrier wall that separates the Creek from the Canal. FPL does not use this intake during normal operations, but does test this system quarterly.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants. The wind turbines will not require water for operations. Consequently, there will be no water discharge as a result of these turbines.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

St. Lucie Units 1 & 2 are licensed for uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core. Each reactor core includes 217 fuel assemblies.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 47,000 megawatt-days per metric ton uranium. In regard to the nuclear capacity uprates, more nuclear fuel will be used due to the increased capacity of each generating unit. No changes in the fuel-handling facilities are required. The addition of the wind turbines will have no fuel-related impact; i.e., no impacts from fuel delivery, storage, waste, or pollution control. Used fuel assemblies are stored in the onsite Nuclear Regulatory Commission (NRC) approved spent fuel storage facilities. Following completion of the uprates, approximately 11 percent more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel-handling facilities are required.

Diesel fuel is used in a number of emergency generators that include four main plant generators, two building generators, and various general purpose diesel engines. The main plant emergency generators will not be changed as a result of either of the two types of generation capacity additions. These emergency generators are for standby use only and are tested to assure reliability and for maintenance. Diesel fuel is delivered to the St. Lucie Plant by truck as needed, and stored in tanks with secondary containment.

p. Air Emissions and Control Systems

The St. Lucie Plant is classified as a minor source of air pollution, since FDEP has issued a Federally Enforceable State Operating Permit (FESOP) to keep emissions less than 100 tons per year for any air pollutant regulated under the Clean Air Act.

The applicable units at the St. Lucie Plant consist of eight large main plant diesel engines, two smaller diesel engines, and various general-purpose diesel engines. The air emissions from these engines are limited by the use of 0.05-percent sulfur diesel fuel and good combustion practices. Best Available Control Technology (BACT) is not applicable to these existing emission units.

Nitrogen oxide (NO_x) emissions from the operation of the diesel engines comprise the limiting pollutant for these diesel units at the St Lucie Plant. The FDEP FESOP limits NO_x emissions to 99.4 tons, which includes fuel use limits on the large main plant emergency diesel engines of 97,000 gallons in any 12-month consecutive period and the smaller building and general purpose diesel engines of 190,000 gallons in any 12-month consecutive period. Also, the Plant may choose to combine the diesel units' fuel-tracking, which then limits the NO_x totals for a 12-month consecutive period to a maximum of 80 tons. There will be no change in the operation or emissions of the diesel engines resulting from either the nuclear capacity uprates or the wind turbines.

In addition, neither of these types of generation capacity additions will result in an increase of carbon dioxide (CO_2) or other greenhouse gas emissions. In fact, both of these increases in generation capacity are projected to result in decreased FPL system-wide emissions of CO_2.

q. <u>Noise Emissions and Control Systems</u>

A field survey and impact assessment of noise expected to be caused by construction activities at the site was conducted for both types of generation capacity additions. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site during construction or operation of either generating capacity additions.

r. <u>Status of Applications</u>

In regard to the nuclear capacity uprates, a Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in December 2007 and a final order issued in September 2008. The FPSC voted to approve the need for the St. Lucie (and Turkey Point) nuclear capacity uprates and the final order approving the need for these capacity additions was issued in January 2008. In regard to the wind turbines, a Site Certification Application is not required. Individual permit applications were submitted for an Environmental Resource Permit (ERP) and the Army Corps of

Engineers Permits in May 2008 and the Coastal Construction Control Line in July 2008. In September of 2007, FPL submitted an application to St. Lucie County for a Conditional Use, Rezoning, and Height Amendment. The local approvals process is ongoing. However, the state and federal permitting process is on hold awaiting completion of local permitting.

Preferred Site # 3: Turkey Point Plant, Miami-Dade County

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear units (Units 3 & 4), two natural gas/oil conventional boiler units (Units 1 & 2), one CC natural gas unit (Unit 5), nine small diesel generators, the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the Everglades Mitigation Bank (EMB).

Turkey Point Units 3 & 4 have been in operation since 1972 and 1973, respectively. The Turkey Point site has been selected as a Preferred Site for the increase in the capacity of its two existing nuclear generating units by approximately 103 MW each. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new or expanded facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing St. Lucie nuclear units, was approved by the FPSC in January 2008. The capacity uprates at Turkey Point are projected to be in-service in 2012.

As previously mentioned, FPL is pursuing licensing for two new nuclear units at the Turkey Point site. Each of these two units would provide 1,100 MW of capacity. Current projections for the in-service dates of these two units, Turkey Point Units 6 & 7, are beyond the 2010-2019 reporting time frame of this document. At the time this document is being prepared, FPL is evaluating what the revised in-service dates for Turkey Point 6& 7 should be for planning purposes. FPL will address those revised in-service dates for planning purposes in its May 3, 2010 cost recovery filing to the FPSC.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Turkey Point plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the Turkey Point Units 3 and 4 generating facility at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The five existing power generation units and support facilities occupy approximately 150 acres of the 11,000-acre Turkey Point Plant site. Support facilities include service buildings, an administration building, fuel oil tanks, water treatment facilities, circulating water intake and outfall structures, wastewater treatment basins, and a system substation. The cooling canal system occupies approximately 5,900 acres. The two 400-megawatt (MW) (nominal) fossil fuel-fired steam electric generation units at the Turkey Point Plant have been in service since 1967 (Unit 1) and 1968 (Unit 2). These units currently burn residual fuel oil and/or natural gas with a maximum equivalent sulfur content of 1 percent. The two 700-MW (nominal) nuclear units have been in service since 1972 (Unit 3) and 1973 (Unit 4). Turkey Point Units 3 and 4 are pressurized water reactor (PWR) units. Turkey Point Unit 5 is a nominal 1,150-MW CC unit that began operation in 2007. Significant features in the vicinity of the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The prominent structures and enclosed facilities and equipment associated with Units 3 & 4 include: the containment building, which contains the nuclear steam supply system, including the reactor, steam generators, reactor coolant pumps, and related equipment; the turbine generator building, where the turbine generator and associated main condensers are located; the auxiliary building, which contains waste management facilities, engineered safety components, and other facilities; and the fuel handling building, where the spent fuel storage pool and storage facilities for new fuel are located. Prominent features beyond the power block area include the intake system, cooling canal system, switchyard, spent fuel storage facilities, and technical and administrative support facilities.

2. **Listed Species**

The construction during the uprating of the units, and operation of the units after the capacity uprating is completed, are not expected to adversely affect any rare, endangered, or threatened species. Listed species known to occur at the site and in the nearby Biscayne National Park that could potentially utilize the site include the peregrine falcon *(Falco peregrinus)*, wood stork *(Mycteria americana)*, American crocodile *(Crocodylus acutus)*, mangrove rivulus *(Rivulus marmoratus)*, roseate spoonbill (*Ajaja ajaja)*, limpkin *(Aramus guarauna)*, little blue heron *(Egretta caerulea)*, snowy egret *(Egretta thula)*, American oystercatcher *(Haematopus palliates)*, least tern *(Sterna antillarum)*, the white ibis *(Eudocimus albus)*, and bald eagle *(Haliaeetus leucocephalus)*. No bald eagle nests are known to exist in the vicinity of the site. The federally listed, threatened American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American crocodile and is attributed with survival improvement and the downlisting of the American Crocodile from endangered to threatened.

3. **Natural Resources of Regional Significance Status**

Significant features in the vicinity on the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park. Biscayne National Park contains 180,000 acres, approximately 95 percent of which is open water interspersed with more than 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant and is adjacent to the Miami-Dade County Homestead Bayfront Park which contains a marina and day-use recreational facilities.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

Turkey Point Units 3 & 4 uses cooling water from a closed-cycle cooling canal system to remove heat from the main (turbine) condensers, and to remove heat from other auxiliary equipment. The existing cooling canals will accommodate the increase in heat load that is associated with the increased capacity from the uprates. The maximum predicted increase in water temperature entering the cooling canal system from the units resulting from the uprates is predicted to be about 2.5°F, from 106.1°F to 108.6°F. The associated maximum increase in water temperature returning to the units is about 0.9°F, from 91.9°F to 92.8°F.

g. <u>Local Government future Land Use Designations</u>

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. <u>Site Selection Criteria Process</u>

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity.

i. <u>Water Resources</u>

Unique to the Turkey Point plant site is the self-contained cooling canal system that supplies water to condense steam used by the plant's turbine generators. The canal system consists of 36 interconnected canals. The cooling canals occupy an area approximately two miles wide by five miles long (5,900 acres), approximately four feet deep. The system performs the same function as a giant radiator. The water is circulated through the canals in a two-day journey, ending at the plant's intake pumps.

j. <u>Geological Features of Site and Adjacent Areas</u>

The Turkey Point Plant lies upon the Floridian Plateau, a partly-submerged peninsula of the continental shelf. The peninsula is underlain by approximately 4,000 to 15,000 feet of sedimentary rocks consisting of limestone and associated formations that range in age from Paleozoic to Recent. Little is known about the basement complex of Paleozoic igneous and metamorphic rocks due to their great depth.

Generally in Miami-Dade County, the surficial aquifer (Biscayne Aquifer) consists of a wedge-shaped system of porous clastic and carbonate sedimentary materials, primarily limestone and sand deposits of the Miocene to late Quaternary age. The Biscayne Aquifer is thickest along the eastern coast and varies in thickness from 80 to 200 feet thick. The surficial aquifer is typically composed of Pamlico Sand, Miami Limestone (Oolite), the Fort Thompson and Anastasia Formations (lateral equivalents), Caloosahatchee Marl, and the Tamiami formation. The lower confining layers below the surficial aquifer range in thickness from 350 to 600 feet and are composed of the Hawthorn Group. Beneath the Hawthorn Group, the Floridan Aquifer System ranges from 2,800 to 3,400 feet thick and consists of Suwannee Limestone, Avon Park Limestone, and the Oldsmar Formations.

k. Projected Water Quantities for Various Uses

The addition of nuclear generating capacity as a result of the uprates will not cause any changes in the quantity or characteristics of industrial wastewaters generated by the facility; therefore, no change in that compliance achievement status is expected. The uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The Turkey Point Plant does not directly withdraw groundwater under its current operations and it will not do so after the capacity uprates. Locally, groundwater is present beneath the site in the surficial or Biscayne Aquifer and in deeper aquifer zones that are part of the Floridan Aquifer System. There will be no effects on those deeper aquifer zones from the capacity uprates.

l. Water Supply Sources and Type

The source of cooling water for Turkey Point Units 3 & 4 is the cooling canal system. There will be no increase in the amount of water withdrawn as a result of the capacity uprates. General plant service water, fire protection water, process water, and potable water are obtained from Miami-Dade County. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns. The water use for the facility will not change as a result of the capacity uprates.

m. Water Conservation Strategies

The existing water resources will not change as a result of the uprates.

n. Water Discharges and Pollution Control

Heated water discharges are dissipated using the existing closed cooling water system and the cooling canal system.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. **Fuel Delivery, Storage, Waste Disposal, and Pollution Control**

Turkey Point Units 3 & 4 utilize uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core. Used fuel assemblies are stored in the onsite NRC-approved spent fuel storage facilities.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at refueling intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 45,000 megawatt-days per metric ton of uranium. Following completion of the uprates, more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel handling facilities are required. Following completion of the uprates, approximately 11 percent more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel-handling facilities are required.

Diesel fuel is used in a number of emergency generators that include four main emergency generators, five smaller emergency generators and various general purpose diesel engines. The emergency generators will not be changed as a result of the capacity uprates. These emergency generators are for stand-by use only and only operated for testing purposes to assure reliability and for maintenance. Diesel fuel for the emergency generators is delivered to the Turkey Point Plant by truck as needed, and stored in tanks with secondary containment.

p. **Air Emissions and Control Systems**

The normal operation of Turkey Point Units 3 & 4 does not create fossil fuel-related air emissions. However, there are 9 emergency generators associated with Units 3 & 4. Four of these nine emergency generators are main plant emergency generators which are rated at 2.5 MW each. The remaining five are smaller emergency generators which are associated with the security system. In addition, various general purpose diesels are used as needed for Units 3 & 4.

Turkey Point Plant Units 3 & 4's associated emergency generators and diesel engines, together with Units 1, 2, & 5, are classified as a major source of air pollution. FDEP has issued a separate Title V Air Operating Permit for the Turkey Point Nuclear Plant (Permit Number 0250003-004-AV). There are no operating limits for the emergency generators or diesel engines. Emergency diesel generators are limited to ultra-low sulfur distillate (0.0015% sulfur). NOx emissions are regulated under Reasonably Available Control Technology (RACT) requirements in Rule 62-296.570(4)(b)7 F.A.C., which limit NO_x emissions to 4.75 lb/MMBtu. The use of 0.05 percent sulfur diesel fuel and good combustion practices serve to keep NO_x emissions under this limit.

q. **Noise Emissions and Control Systems**

A field survey and impact assessment of noise expected to be caused by activities associated with the uprates was conducted. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site.

r. **Status of Applications**

A Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in January 2008 and a final order was issued in October 2008. The FPSC voted to approve the need for the Turkey Point (and St. Lucie) uprates and the final order approving the need for this additional nuclear capacity was issued in January 2008.

Preferred Site # 4: Cape Canaveral Plant, Brevard County

This site is located on the existing FPL Cape Canaveral Plant property in unincorporated Brevard County. The site is bound to the east by the Indian River Lagoon and on the west by a four lane highway (US. 1). The city of Port St. Johns is located less than a mile away. A rail line is located near the plant.

The existing 788 MW (summer) of generating capacity at FPL's Cape Canaveral site occupies a portion of the 43 acres that are wholly owned by FPL. The generating capacity is made up of steam units (Units 1 & 2).

The Cape Canaveral Plant site has been listed as a Potential Site in previous FPL Site Plans for both CC and simple cycle generation options. FPL is proposing, for resource planning purposes, to modernize the existing Cape Canaveral Plant, to be renamed the

Cape Canaveral Next Generation Clean Energy Center (CCEC), by replacing the existing generating units with a modern, highly efficient, lower-emission next-generation clean energy center using the latest CC technology. The existing two (2) steam units will first be dismantled and removed from the site and will be replaced by a single new CC unit.

a. Geological Survey (USGS) Map

A USGS map of the Cape Canaveral Plant site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the general layout of the CCEC generating facilities at the site is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing land uses on the site are primarily dedicated to electrical generation; i.e., FPL's existing Cape Canaveral Units 1 & 2. The existing land uses that are adjacent to the site consist of single- and multi-family residences to the south and southwest, commercial property to the northwest, utility systems to the west, and a private medical/office facility to the north.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The natural environment surrounding the site includes the Indian River Lagoon to the east and upland scrub, pine and hardwoods to the north and south. Vegetation with the approximately 45-acre offsite construction laydown and parking area (located west of U.S. Highway 1) consists of open land, upland scrub, pine, hardwoods along with exotic plant species.

2. Listed Species

No adverse impacts to federally or state-listed terrestrial plants and animals are expected in association with construction at the Site, due to the existing developed nature of the Site and lack of suitable onsite habitat for listed species. Federal- or state-listed terrestrial plants and animals inhabiting the offsite construction laydown and parking area are limited to the state-listed gopher tortoise and the state- and federally-listed scrub jay. The warm water discharges from the plant attract manatees, an endangered species. FPL is working closely with state and federal wildlife agencies to ensure protection of the manatees during the modernization process and upon operation of the new plant. FPL will be complying with several manatee related conditions of certification to ensure the protection of the manatees during this time.

3. **Natural Resources of Regional Significance Status**

The construction and operation of a natural gas-fired CC generating facility at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design option is to replace the existing steam generating units (Units 1 & 2) with one new 1,219 MW (approximate) CC unit consisting of three new combustion turbines (CT), three new heat recovery steam generators (HRSG), and a new steam turbine. The new CC unit would be in-service in mid-2013. Natural gas delivered via pipeline is the primary fuel type for this unit with ultra-low sulfur light oil serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the site is "Public Utilities" and the area has been rezoned to GML-U. Designations for the surrounding area are primarily "Community Commercial" and "Residential". The Indian River Lagoon is to the east of the site.

h. **Site Selection Criteria Process**

The Cape Canaveral Plant has been selected as a preferred site for a site modernization due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. However, there are environmental benefits of replacing the existing steam units with a new CC unit including a significant reduction in system air emissions and improved aesthetics at the site.

i. **Water Resources**

Condenser cooling for the steam cycle portion of the new plant and auxiliary cooling will come from the existing cooling water intake system. Process, potable, and irrigation water for the new plant will come from the existing City of Cocoa's potable water supply.

j. **Geological Features of Site and Adjacent Areas**

FPL's Cape Canaveral Plant is located on the Atlantic Coastal Ridge and is at an approximate elevation of 12 feet above mean sea level (msl). The land consists primarily of fine to medium sand that parallels the coast. There is a lack of shell as it was deposited during a time of transgression. The base of the sedimentary rocks is made up of a thick, primarily carbonate sequence deposited during the Jurassic age through the Pleistocene age. Starting in the Miocene age and continuing through the Holocene age, siliciclastic sedimentation became more predominant. The basement rocks in this area consist of low-grade metamorphic and igneous intrusives, which occur several thousand feet below land surface and are Precambrian, Paleozoic, and Mesozoic in age.

k. **Projected Water Quantities for Various Uses**

The estimated quantity of water required for processing is approximately 0.232 million gallons per day (mgd) for uses such as process water and service water. Approximately 619 million gallons per day (mgd) of cooling water would be cycled through the once-through cooling water system. Potable water demand is expected to average .001 mgd.

l. **Water Supply Sources by Type**

The new plant will continue to use the Indian River Lagoon water as the source of once-through cooling water. Such needs for cooling water will comply with the existing St. John's River Water Management District (SJRWMD) Consumptive Use Permit (CUP). Process, potable, and irrigation water for the new plant will come from the existing City of Cocoa's potable water supply.

m. **Water Conservation Strategies Under Consideration**

No additional water sources will be required as a result of the modernization project.

n. Water Discharges and Pollution Control

The modernized site will utilize portions of the existing once-through cooling water systems for heat dissipation. The heat recovery steam generator blowdown will be mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's once-through cooling water system. Stormwater runoff will be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for the new unit would be transported to the site via a pipeline. New on-site gas compressors may be installed to raise the gas pressure of the existing pipeline for the new unit. Ultra-low sulfur light fuel oil would be received by truck or barge from Port Canaveral and stored in an existing above-ground storage tank.

p. Air Emissions and Control Systems

The emission rates of CCEC would decrease by almost 100-fold from the existing Cape Canaveral Plant, resulting in substantial annual emissions reductions and increased air quality benefits. The use of natural gas and ultra-low sulfur light fuel oil and combustion controls would minimize air emissions from the unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of the new CCEC plant will incorporate features that would make it among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise from the operation of the new unit will be within allowable levels.

r. Status of Applications

The FPSC voted to approve the need for the modernization project and the need order was issued in September 2008. The project received final state certification on October 9, 2009, through the issuance of a final order signed by the Secretary of the DEP.

Preferred Site # 5: Riviera Plant, Palm Beach County

This site is located on the existing FPL Riviera Plant property primarily within Riviera Beach, Palm Beach County (with a small portion of the Site in West Palm Beach). The site is bound to the east by the Lake Worth Lagoon (Intracoastal Waterway) and on the west by a four lane highway (US. 1). The site has barge access via the Port of Palm Beach. A rail line is located near the plant.

The current site generating capacity is made up of two (2) operational 300 MW (approximate) steam generating units (Units 3 & 4). Units 1 & 2 have been retired and dismantled and are no longer on the plant site.

The Riviera Plant site has been listed as a Potential Site in previous FPL Site Plans for both CC and simple cycle generation options. FPL is proposing, for resource planning purposes, to modernize the existing Riviera Plant, to be renamed the Riviera Beach Next Generation Clean Energy Center (RBEC), by replacing the existing generating units with a modern, highly efficient, lower-emission next-generation clean energy center using the latest CC technology. The existing two steam units will first be removed from the site and will be replaced by a single new CC unit.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Riviera site is found at the end of this chapter.

b. Proposed Facilities Layout

A general layout of the RBEC generating facilities is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing Riviera Plant currently consists of two 300 MW (approximate) units with conventional dual-fuel fired steam boilers and steam turbine units. The plant site includes minimal vegetation and a landscape buffer area south of the power plant. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the site is comprised of facilities related to electric power generation for the existing Riviera Plant. The site is located on the Intracoastal waterway which provides warm water refugia for manatees during cold winter days.

2. Listed Species

No adverse impacts to federally or state-listed terrestrial plants and animals are expected in association with construction at the Site, due to the existing developed nature of the Site and lack of suitable onsite habitat for listed species. The warm water discharges from the plant attract manatees, an endangered species. FPL is working closely with state and federal wildlife agencies to ensure protection of the manatees during the modernization process and upon operation of the new plant. FPL will be complying with several manatee related conditions of certification to ensure the protection of the manatees during this time.

3. Natural Resources of Regional Significance Status

The construction and operation of a natural gas-fired CC generating facility at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to replace the existing units (Units 3 & 4) with one new 1,219 MW (approximate) unit consisting of three new combustion turbines (CT), three new heat recovery steam generators (HRSG), and a new steam turbine. The new CC unit would be in service in mid-2014. Natural gas delivered via pipeline is the primary fuel type for the unit with ultra-low sulfur light oil serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the site is "Utility". The Port of Palm Beach is to the north of the site. Designation to the west of the site is "Commercial". To the south of the site is "Residential" and is in the City of West Palm Beach.

h. **Site Selection Criteria Process**

The Riviera plant has been selected as a Preferred Site to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. However, there are environmental benefits of replacing the existing steam units with a new CC unit including a significant reduction in system air emissions and improved aesthetics at the site.

i. **Water Resources**

Water from the Lake Worth Lagoon (Intracoastal waterway) is currently used for once-through cooling water. The new plant will utilize portions of the existing once through cooling water intake and discharge structures. Water for cooling pump seals and irrigation will come from three onsite surficial aquifer wells. Process and potable water for the converted plant will come from the existing City of Riviera Beach potable water supply.

j. **Geological Features of Site and Adjacent Areas**

FPL's Riviera Plant site is underlain by the surficial aquifer system. The Surficial aquifer system in eastern Palm Beach County is primarily composed of sand, sandstone, shell, silt, calcareous clay (marl), and limestone deposited during the Pleistocene and Pliocene Epochs. The sediments forming the aquifer system are the Pamlico Sand, Fort Thompson Formation (Pleistocene) and the Caloosahatchee Marl (Pleistocene and Pliocene). Permeable sediments in the upper part of the Tamiami Formation (Pliocene) are also part of the aquifer system. The sediments in the eastern portion of the county are appreciably more permeable than in the west due to better sorting and less silt and clay content.

The surficial aquifer is underlain by at least 600 feet the Hawthorn formation (confining unit). The Floridan Aquifer System underlies the Hawthorn formation.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for processing is approximately 0.232 million gallons per day (mgd) for uses such as process water and service water. Approximately 600 mgd of cooling water would be cycled through the once-through cooling water system. Potable water demand is expected to average .001 mgd.

l. Water Supply Sources by Type

The new plant will continue to use the Lake Worth Lagoon water as the source of once-through cooling water. Water for cooling pump seals and irrigation will come from on-site surficial aquifer wells currently permitted by SFWMD. Process and potable water for the new plant will come from the existing City of Riviera Beach's potable water supply.

m. Water Conservation Strategies Under Consideration

No additional water sources will be required as a result of the modernization project.

n. Water Discharges and Pollution Control

The new plant will utilize portions of the existing once-through cooling water system for heat dissipation. The heat recovery steam generator blowdown will be mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's once-through cooling water system prior to discharge. Stormwater runoff will be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for the new unit would be transported to the site via a pipeline. New gas compressors may be installed to raise the gas pressure of the existing pipeline to the appropriate level for the converted unit. Ultra-low sulfur light fuel oil would be received by truck, pipeline or barge and stored in a new above-ground storage tank.

p. **Air Emissions and Control Systems**

The regulated air emissions at the new plant would be more than 90 percent lower than the existing Riviera Plant's emissions are, resulting in significant annual emissions reductions and air quality benefits. The use of natural gas and ultra-low sulfur light fuel oil and combustion controls would minimize air emissions from the unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of RBEC would incorporate features that will make it among the most efficient and cleanest power plants in the State of Florida.

q. **Noise Emissions and Control Systems**

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site.

r. **Status of Applications**

The FPSC voted to approve the need for the modernization project and the need order was issued in September 2008. The project received final state certification on November 24, 2009, through the issuance of a final order signed by the Secretary of the DEP.

Preferred Site #6: Space Coast Next Generation Solar Energy Center, Brevard County

The Space Coast site is located at Section 13, Township 23 South, and Range 36 East, North of North Courtenay Parkway. FPL is leasing approximately 60 acres from Kennedy Space Center in Brevard County. This Space Coast site has been selected as a Preferred Site for the addition of a 10 MW PV generation facility. The Space Coast Next Generation Solar Energy Center is expected to be in operation by the end of 2010. This

Site has the potential to expand by another 10 MW. Also, FPL is evaluating the potential for expansion beyond the existing site.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the Space Coast Next Generation Solar Energy Center plant site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the Space Coast Next Generation Solar Energy Center generating facility is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

The site is inactive. The site was previously dedicated to agricultural use as citrus groves. There are no structures on the site and the majority of the vegetation is citrus grove.

e. **General Environment Features On and In the Site Vicinity**

1. **Natural Environment**

The surrounding land use is predominantly agriculture. FPL was able to design the PV facility to avoid most of the impacts to natural wetlands.

2. **Listed Species**

Wildlife resources at the site were evaluated in February 2008 through pedestrian surveys. There were no listed species observed.

3. **Natural Resources of Regional Significance Status**

The construction and operation of a PV generating facility at this location is not expected to have any adverse impacts on parks or recreation areas. Construction will result in minimal wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design consists of 10 MW of PV technology. No mitigating options are deemed necessary at the site.

g. **Local Government future Land Use Designations**

Future land use designation for the site is Spaceport Management as designated by the Brevard County Future Land Use Map.

h. **Site Selection Criteria Process**

The site has been selected as a Preferred Site for the installation of a PV technology due to consideration of various factors including its suitability for a PV facility of this magnitude and the cooperation of the Kennedy Space Center.

i. **Water Resource**

No water will be required at the PV facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water would be brought to the site by truck.

j. **Geological Features of the Site and Adjacent Areas**

The surface and near-surface deposits of east-central Florida range from surficial unconsolidated sands to well indurated limestones and dolomites at depth. In ascending order the four main geologic units present in east-central Florida are: (i) Eocene limestones; (ii) Lower and Middle Miocene compact silt and clays; (iii) Upper Miocene and Pliocene silty and clayey sands; and (iv) Pleistocene and Recent age sands with interbedded shell layers.

k. **Projected Water Quantities for Various Uses**

The projected water use for the PV facility is expected to be minimal with water being used occasionally only to clean the PV panels.

l. **Water Supply Sources and Type**

At this time, it is expected that natural rainfall will be sufficient to keep the solar panels clean. In the event that additional water is required, a small amount of water may be occasionally trucked in to clean the PV panels.

m. **Water Conservation Strategies**

FPL constructed this PV facility knowing it would not use water for operation and would only need a minimal amount for cleaning the PV panels.

n. **Water Discharges and Pollution Control**

There will not be any water discharges or pollution as a result of this facility

o. **Fuel Delivery, Storage, Waste Disposal, and Pollution Control**

The facility will use the sun for fuel. Therefore, there will not be any fuel delivery, storage, waste, or pollution at this site.

p. **Air Emissions and Control Systems**

No air emissions will be emitted from this facility.

q. **Noise Emissions and Control Systems**

Noise expected during construction is expected to be below noise levels allowed by Brevard County. No noise will be emitted from this facility during operation.

r. **Status of Applications**

FPL received an Environmental Resource Permit (ERP) from the St. Johns Water Management District in April 2009 and a U.S. Army Corps of Engineers permit in December 2008 for the 10 MW site. .

Preferred Site #7: Martin Next Generation Solar Energy Center, Martin County

The Martin Next Generation Solar Energy Center (MSEC) is located on the existing FPL Martin Plant site in unincorporated Martin County, Florida. The Martin Plant site is located in southwestern Martin County about 40 miles northwest of West Palm Beach and about 1.3 miles east of Lake Okeechobee (Figure 2.1-1). The Martin Plant site is bounded by State Road (SR) 710 and a CSX Railroad line (east and north), a Florida East Coast Railway line and SFWMD L-65 Canal (west), and the St. Lucie Waterway (south).The MSEC Project will be constructed in an approximately 600-acre area (Project Area) within FPL's existing 11,300-acre Martin Plant site. The land surrounding the site is owned by FPL and acts as a buffer zone.

The site has been selected as a Preferred Site for the addition of approximately 75 MW of solar thermal generation. The facility will produce steam that will replace steam that would otherwise have been produced by burning natural gas in one of the existing CC units at the site, Martin Unit 8. The Martin Next Generation Solar Energy Center is expected to be in operation by the end of 2010.

There also is potential for an additional 75 MW of photovoltaic or solar thermal on the Martin Plant Property in the future. Adjacent farmlands are also being considered for additional photovoltaic facilities.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the Martin Next Generation Solar Energy Center plant site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the Martin Next Generation Solar Energy Center generating facility is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

Total acreage for the existing Martin Plant site is approximately 11,300 acres, which represents land owned by FPL. The Martin Plant site consists of a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of embankment) and approximately 400 acres for existing Units 1 through 4, Unit 8, and associated facilities. Units 1 & 2 are nominal 800-MW steam electric generating units that use natural gas and low-sulfur residual oil. Units 3 & 4 are nominal 500-MW natural gas-fired CC units. Unit 8 is a natural gas fired 4-on-1 CC unit with a nominal capacity of 1,100 MW that began operation in 2005. Light oil is used as backup in Unit 8. The other onsite facilities include water and wastewater treatment facilities, residual and light fuel oil storage, switchyards and transmission lines, offices, warehouses, maintenance buildings, and other miscellaneous uses.

Adjacent areas include agricultural uses such as croplands, pastures, and groves account for much of the land use and cover within 5 miles of the Martin Plant site. Three types of wetlands, forested freshwater, non-forested freshwater, and mixed forested and forested freshwater also account for a great deal of nearby land use.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The portions of the Martin Plant site that will be affected by the construction of the MSEC are about 550 acres that will be utilized for solar arrays and construction facilities. The solar arrays will be located east of the existing Unit 8. Activities associated with construction will occupy about 100 acres. This will include construction laydown, parking, and trailers. These areas will be cleared of any vegetation. The area for the heat exchangers will be near Unit 8 and this area has been previously impacted by the construction of Units 3, 4, and 8.

2. Listed Species

Threatened and endangered species within the project area are limited to avian species and gopher tortoise. No listed species of plants were identified within the MSEC project area. Due to the presence of large areas of similar habitat both within the Northwest Mitigation Area and areas north of the existing transmission line right-of-way (ROW) adjacent to the project area, and the highly mobile nature of protected avian species, no significant adverse impacts to federally or state listed animals are expected. Creation of wood stork foraging ponds and sandhill crane habitat within the Northwest Mitigation Area provides suitable habitat to offset the loss of shallow hydroperiod wetlands within the project area.

Gopher tortoises are classified as threatened by the Florida Fish and Wildlife Conservation Commission (FFWCC), but are not listed federally by the U.S. Fish and Wildlife Service (USFWS). Gopher tortoise burrows were observed in the palmetto prairie and woodland pasture. Other listed species are known to utilize gopher tortoise burrows (commensal species), including the Eastern indigo snake (*Drymarchon corais couperi*; federally and state threatened), gopher frog (*Rana capito*; state species of special concern), and Florida mouse (*Podomys floridanus*; state species of special concern). A permit was obtained to relocate the gopher tortoises and any commensal species. Construction and operation at the site is not expected to affect any rare, endangered, or threatened species.

3. Natural Resources of Regional Significance Status

The construction and operation of a solar thermal facility at this location is not expected to have any adverse impacts on parks or recreation areas.

Construction will result in minimal wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

The Florida Department of State, Division of Historical Resources, has determined that no significant archaeological or historical sites are recorded or are likely to be present within the project area. As a result no construction impacts on historic properties listed or eligible for listing in the National Register of Historic Places, or otherwise of historical or archaeological value, are anticipated.

f. **Design Features and Mitigation Options**

The design consists of approximately 75 MW of solar thermal technology. FPL has already undertaken an extensive wetland mitigation program on a 1,130-acre parcel northwest of the existing Martin Plant generating units. That mitigation program was deemed successful by the SFWMD in 2001. All wetland impacts associated with the MSEC have been fully mitigated through this now-successful wetland and upland mitigation effort.

g. **Local Government future Land Use Designations**

The Martin Plant site that includes Units 1 & 2 was developed prior to the county's adoption of a future land use map. In 1982, at the time of the original land use plan map adoption, the portion of the Martin Plant site surrounding the existing units was designated Industrial. The Electric Utility Element of the Comprehensive Plan acknowledged FPL's then current plans to construct two integrated coal gasification combined cycle (IGCC) plants at the Martin Plant site and encouraged the facilities to be developed under the industrial planned unit development [PUD(i)] zoning designation. In September 1988, FPL requested a comprehensive plan land use amendment to industrial for the licensing of the Martin Coal Gasification/Combined Cycle (CG/CC) Project Area and a rezoning of that area to PUD(i). In August 1989, the Martin County Board of County Commissioners (BOCC) approved the comprehensive plan amendment and the rezoning request. In June 2008, with the BOCC approval of the rezoning, a PUD Zoning Agreement was executed between Martin County and FPL in which development standards and special conditions were addressed. Most of the special conditions were addressed during earlier phases of developing the Martin Plant site. An amendment of the PUD Zoning Agreement was requested by FPL to allow renewable energy facilities to be located within the PUD area. Subsequent to the certification of the CG/CC project, which includes the area of the MSEC, Martin County has amended its future land use element and map to designate 7,300 acres in the Martin Plant site as Public Utilities – Major Public Power Generation Facilities.

h. Site Selection Criteria Process

The site has been selected as a Preferred Site due to consideration of various factors including available land area and proximity to an existing generating unit (Martin Unit 8) to which the steam generated by the solar thermal facility could be fed.

i. Water Resource

There will be no water used at the solar thermal facility except the small amount needed to occasionally clean the solar mirrors. The additional water needed for mirror cleaning is already within the previously approved allocation of water for the Martin Plant site.

j. Geological Features of the Site and Adjacent Areas

Borings drilled in the area just east of the existing Unit 8 show that the predominant soil type is sand from the ground surface [approximately 30 feet above mean sea level (ft-msl)] to −70 ft-msl (negative number denotes feet below sea level). The sands vary in color from light to dark gray and brown. Clayey sand and sandy clay seams from a few inches to several feet in thickness are generally found at 10 ft-msl. A thin layer of greenish-gray sandy clay was found in the borings at approximately −25 ft-msl. The Pamlico and Anastasia Formations extend from the ground surface (20 to 30 ft-msl) to an average of −3 ft-msl. These strata consist of fine sands and silty sands with shell fragments. Thin beds of limestone and cemented sand occur sporadically at depths ranging from 2 to 4.5 ft-msl in localized areas; this zone may represent the boundary between the Pamlico and Anastasia Formations. In areas where the cemented sands and limestone are absent, it is not possible to differentiate the two formations.

The underlying Caloosahatchee Group extends to an average −80 ft-msl. This formation can be subdivided into two units, namely an upper limestone interbedded with sand and shell present to an average −12 ft-msl, and a lower unit of silty sand with shell fragments and shell beds to −80 ft-msl. The Tamiami Formation underlies the Caloosahatchee from −105 ft-msl to −150 ft-msl. This formation consists of silty sand varying with depth to clayey sand from −72 ft-msl. The color of the formation also varies from gray in the sands to predominantly green in the clayey zone.

The top of the Hawthorn Group occurs at approximately −105 ft-msl to −150 ft-msl. These elevations are based on the logs of test wells and exploratory borings drilled in the area. The Hawthorn, approximately 550 ft thick, consists predominantly of greenish clay with subordinate amounts of shell, limestone, silt, and sand. Major limestone zones generally occur near the base of the formation. Due to very low vertical permeability, the Hawthorn acts as a confining bed overlying the Floridan Aquifer.

k. Projected Water Quantities for Various Uses

Washing mirrors requires about 50 gallons per 120 mirrors (i.e., a 50 meter section). Based on the amount of mirrors for the MSEC, about 75,000 gallons per washing will be required. This amount of water is estimated to be no more than about 2 million gallons per year for cleaning mirrors.

l. Water Supply Sources and Type

The plant water use for MSEC can be accommodated by the current authorization for water in the Conditions of Certification (PA89-27L). The amount of water required by the MSEC is estimated to not exceed about 2 million gallons per year for cleaning mirrors, or an annual average of about 5 gallons per minute (gpm). The usage will be intermittent, with maximum usage of about 75,000 gallons every 1 or 2 weeks during periods without rain and depending upon the reflectivity of the mirrors. The source of water for the MSEC is the existing demineralized water system.

m. Water Conservation Strategies

FPL plans to construct this solar thermal facility knowing it will use very little water for operation.

n. Water Discharges and Pollution Control

There will not be any water discharges or pollution as a result of this facility.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The facility will use the sun for fuel. Therefore, there will not be any fuel delivery, storage, waste, or pollution at the site from the operation of the solar thermal facility.

p. Air Emissions and Control Systems

There will be no SO_2, NO_x, or CO_2 emissions from the solar thermal facility and its operation will result in reductions of FPL system emissions for all three types of emissions.

There will be minor amounts of volatile organic compounds (VOCs) released from the expansion tanks as a result of decomposition products of heat transfer fluids (HTF). Based on reported values from FPL Energy SEGS facilities in California, the VOC emissions from the MSEC will be about 0.8 tons per year (TPY). This amount would classify these emissions as insignificant activities and the amount is well below the threshold requiring permitting under FDEP rules in 62-210.300, F.A.C. A generic exemption is that emissions of any regulated pollutant be less than 5 TPY. The 5 TPY applies to the "potential-to-emit" for the emission unit, which would be 8,760 hours/year unless restricted as an enforceable permit condition in a permit. The exemption covers the requirement to obtain construction permits required pursuant to Rule 62-210.300(1), F.A.C.

q. Noise Emissions and Control Systems

Noise during construction is expected to be below noise level allowed by Martin County. There will not be any noise from the solar thermal facility during operation.

r. Status of Applications

FPL submitted an application for a Site Certification Modification for the Martin Next Generation Solar Energy Center to the FDEP in May 2008. FPL received the site certification modification approval in August 2008.

IV.F.2 Potential Sites for Generating Options

Ten (10) sites are currently identified as Potential Sites for near-term future generation additions to meet FPL's capacity and energy needs.[4]

These sites have been identified as Potential Sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these Potential Sites offer a range of considerations relative to engineering and/or costs associated with the construction and operation of feasible technologies. In addition, each Potential Site has different characteristics that will require further definition

[4] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites and other greenfield sites. Greenfield sites that FPL currently does not own, or for which FPL has not currently secured the necessary rights to, are not specifically identified as Potential Sites in order to protect the economic interests of FPL and its customers.

and attention. Solely for the purpose of estimating water requirements for each site, it was assumed that either one dual-fuel (natural gas and light oil) simple cycle combustion turbine (CT) or a natural gas-fired CC unit would be constructed at the Potential Sites unless otherwise noted. A simple cycle CT would require approximately 50 gallons per minute (gpm) for both process and cooling water (assuming air cooling). A CC unit would require approximately 150 gpm for service and process water and approximately 14 million gallons per day (mgd) for cooling water depending upon the water source and associated water quality. If an existing power plant site is ultimately selected for converting an existing unit(s), the water requirements discussed above for a CC unit would be approximately correct for the converted unit. If a renewable energy generating technology, such as photovoltaic or solar thermal, is ultimately selected for one of these sites, the water requirements would be less than those for CT or CC facilities.

Permits are presently considered to be obtainable for each of these sites. No significant environmental constraints are currently known for any of these sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time, FPL considers each site to be equally viable.

Potential Site # 1: Babcock Ranch , Charlotte County

This site is located within the Babcock Ranch Community on the north side of Truckers Grade, approximately 10.5 miles north of the intersection of SR-80 and SR-31 and 1.1 miles east of SR-31. The project is bordered on the north by the Babcock Ranch Reserve owned by the State of Florida. The site is within the SFWMD and, therefore, the drainage would be in accordance with the SFWMD Basis of Review. Permitting of the surface water management system would be through the Florida Department of Environmental Protection (FDEP) - South District based on a pre-application meeting. This site is a possibility for an FPL photovoltaic (PV) facility.

a. U.S. Geological Survey (USGS) Map

A map of this site is found at the end of this chapter.

b. Land Uses

Existing Land Use on the site is agricultural. FPL would attempt to re-zone the property to PD-P1 which will allow for electrical generation.

c. **Environmental Features**

FPL anticipates mitigating for any panther and/or wetland impacts as a result of the project.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility.

e. **Supply Sources**

No water will be required at the PV facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water would be brought to the site by truck.

Potential Site # 2: DeSoto Solar Expansion, DeSoto County

The DeSoto site is located at 4051 Northeast Karson Street approximately 0.3 miles east of US 17 and immediately north of Bobay Road in Arcadia, Florida. The site is located in Sections 26, 27, & 35, Township 36 South, and Range 25 East. FPL owns an approximate 13,000 acre parcel in DeSoto County. FPL has designated approximately 1,523 acres for development of a photovoltaic (PV) facility. The land surrounding the site is owned by FPL and acts as a buffer zone.

The DeSoto site was previously selected as the site for the addition of a 25 MW PV facility, which is currently operational. There is also a potential to create an additional 275 MW PV generating facility which would be implemented in phases on the additional land.

a. **U.S. Geological Survey (USGS) Map**

A map of this site is found at the end of this chapter.

b. **Land Uses**

Existing Land Use on the site is agricultural.

c. **Environmental Features**

There are no significant environmental features on the site.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility.

e. **Supply Sources**

No water will be required at the PV facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water would be brought to the site by truck.

Potential Site # 3: Florida Heartland Solar, Glades County

This site is located within Glades County, Florida off of SR 78. This site is a possibility for an FPL PV facility.

a. **U.S. Geological Survey (USGS) Map**

A map of this site is found at the end of this chapter.

b. **Land Uses**

The existing land uses on the site is agriculture.

c. **Environmental Features**

FPL anticipates mitigating for any panther and/or wetland impacts as a result of the project.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility.

e. **Supply Sources**

No water will be required at the PV facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water would be brought to the site by truck.

Potential Site # 4: Fort Myers Plant, Lee County

FPL's existing 460-acre Fort Myers property is located just east of Interstate 75 in Lee County and is adjacent to the Caloosahatchee River. The existing facilities on the site include one 1,440 MW (approximate) CC unit, 12 gas turbines, each with an approximate capacity of 54 MW, and two combustion turbines, each with an approximate capacity of 160 MW.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the Fort Myers plant site is found at the end of this chapter.

b. **Land Uses**

The land on the site is currently dedicated to industrial use with surrounding grassy and landscaped areas. Much of the site has been used in recent years for direct plant construction activities. The adjacent land uses include light commercial and retail to the east of the property, plus some residential areas located toward the west.

c. **Environmental Features**

Mixed scrub with some hardwoods can be found to the east and further south. The Caloosahatchee River is designated as critical habitat for manatees.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

The available water source is the Caloosahatchee River and the available groundwater source is the sandstone aquifer. FPL is aware that the Caloosahatchee River provides habitat for a variety of listed species. Prior to definitive site selection, FPL will take into account impingement and entrainment impacts as well as potential water quality impacts as a result of any new generating unit addition.

Potential Site # 5: Hendry County

FPL is currently evaluating potential sites in Hendry County for a future photovoltaic facility for up to 100 MW. Sites currently under investigation are approximately 1500 acres. No specific locations have been selected at this time.

a. **U.S. Geological Survey (USGS) Map**

Not available because a specific site has not been selected at this time.

b. **Land Uses**

Hendry County is predominantly agricultural land use.

c. **Environmental Features**

Not available because a specific site has not been selected at this time.

d. **Water Quantities**

Minimal amounts of water would be required for a photovoltaic facility.

e. **Supply Sources**

No water will be required at the PV facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water would be brought to the site by truck.

Potential Site # 6: Lauderdale Plant, Broward County

The Lauderdale site is located in Eastern Broward County approximately 5 miles inland from Dania Beach and less than 2 miles west of Ft. Lauderdale International Airport. The site is bounded on the south by Dania Cutoff Canal, on the east by S.W. 30th Avenue, and on the North by I-595.

The existing approximately 1,700 MW of generating capacity at FPL's Lauderdale site occupies a portion of the approximately 210 acres that are wholly owned by FPL. The generating capacity is made up of two CC units (Units 4 & 5), and 24 simple cycle gas turbine (GT) units.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site is found at the end of this chapter.

b. **Land Uses**

The existing power plant facilities are located on approximately 130 acres. The existing site has been in use since the 1920s and is adjacent to a county resource recovery project.

c. **Environmental Features**

To the north of the power plant is an area of mixed uplands with a scattering of small wetlands. Manatees are known to inhabit the waters nearby the plant.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Existing groundwater or the municipal water supply are potential water sources. FPL will also consider the potential for alternative water development options at this site.

Potential Site # 7: Manatee Plant, Manatee County

The existing FPL Manatee Plant 9,500-acre site is located in unincorporated north-central Manatee County. The existing power generating facilities are located in all or portions of Sections 18 and 19 of Township 33S, Range 20-E. The plant site lies approximately 5 miles east of Parrish, Florida. It is approximately 5 miles east of U.S. 301 and 9.5 miles east of Interstate Highway 75 (I-75). The existing plant is approximately 2.5 miles south of the Hillsborough-Manatee County line; a portion of the north property boundary of the plant site abuts the county line. State Road 62 (SR 62) is about 0.7 mile south of the plant, with the plant entrance road going north from that highway. This site is a possibility for an FPL PV or solar thermal facility.

a. **U.S. Geological Survey (USGS) Map**

A map of the site is found at the end of this chapter.

b. **Land Uses**

Existing Land use on the site is agricultural. FPL is attempting to rezone the property to PD-PI which will allow for electrical generation.

c. **Environmental Features**

FPL anticipates mitigating for any gopher tortoise and/or wetland impacts as a result of the project.

d. **Water Quantities**

Minimal amounts of water would be required for a solar thermal facility.

e. **Supply Sources**

The existing water supply could be used for the water required to clean the mirrors for a solar thermal facility.

Potential Site # 8: Northeast Okeechobee County

This site is located within Okeechobee County, Florida. The northeastern portion of Okeechobee County has been identified as an area with the potential to provide a project site that requires strategic consideration. Further assessments of NE Okeechobee County are anticipated to determine suitability of a specific site.

a. **U.S. Geological Survey (USGS) Map**

Not available because a specific site has not been selected at this time.

b. **Land Uses**

Northeast Okeechobee County is predominantly agricultural land use.

c. **Environmental Features**

Not available because a specific site has not been selected at this time.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Existing groundwater is a potential water source.

Potential Site # 9: Southwest Indian River County

This site is located within Indian River County, Florida. The southwestern portion of Indian River County has been identified as an area with the potential to provide a project site that requires strategic consideration. Further assessments of SW Indian River County are anticipated to determine suitability of a specific site.

a. **U.S. Geological Survey (USGS) Map**

Not available because a specific site has not been selected at this time.

b. **Land Uses**

Southwestern Indian River County is predominantly agricultural land use.

c. **Environmental Features**

Not available because a specific site has not been selected at this time.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Existing groundwater is a potential water source.

Potential Site # 10: West Broward, Broward County

FPL has identified the Andytown Substation property in western unincorporated Broward County as a potential site for the addition of new generating capacity and FPL refers to this potential site as the West Broward site. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site has been included at the end of this chapter.

b. **Land Uses**

The land uses for the site were designated as agricultural use.

c. **Environmental Features**

Extensive low-quality wetlands are present on the site. Construction and operation of a new facility on this site would not be expected to adversely affect any rare, endangered, or threatened species.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for both process and cooling water (assuming air cooling) and up to 14 million gallons per day (mgd) for cooling water.

e. **Supply Sources**

Groundwater from the shallow aquifer or a local source of reclaimed (reuse) water has been identified as potential water sources. The Floridan Aquifer has also been identified as a potential cooling water source. FPL will also consider the potential for alternative water development options at this site.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints: external limitations and internal limitations. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance that is available to the FPL system as well as the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In the loss of load probability (LOLP) portion of its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new units that minimize adverse impacts to the flow of electricity within FPL's system. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations and by evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system.

Both of these site- and system-related transmission costs are developed for each different unit/unit location option or groups of options. In addition, transfer limits for capacity and energy that can be imported into the Southeastern region of FPL's system are also developed for use in FPL's production costing analyses. (A further discussion of the Southeastern Florida region and the need to maintain a regional balance between generation and transmission contributions is found in Chapter III.)

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's planned transmission facilities to interconnect and integrate FPL's resource plans and those that must be certified under the Transmission Line Siting Act are presented in Chapter III.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.[4]

The load forecast that is presented in FPL's 2010 Site Plan was developed in February 2010. FPL has not performed sensitivity analyses on forecasts that differ from this recently developed load forecast.

[4] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis (i.e., when only new generating options are considered), the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its fuel price forecasts are discussed in Chapter III of this document. FPL used three fuel and four environmental compliance cost forecasts in the 2009 nuclear cost recovery filings. FPL utilized one of these fuel cost forecasts, and one of these environmental compliance cost forecasts in its DSM Goals analyses.

The resource plan presented in this Site Plan is based, in part, on those prior analyses. For that reason, this resource plan, with the recently developed February 2010 load forecast, has not been further tested for different fuel cost forecasts.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item # 3, FPL used up to three fuel cost forecasts in its 2009 resource planning analyses. While these forecasts did not represent a constant cost differential between oil/gas and coal, a variety of fuel cost differentials were represented in these forecasts.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 in Chapter I, and Schedule 8 in Chapter III, present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options in its resource planning work. A summary of this information for the new capacity options FPL projects to add over the planning horizon is presented on the Schedule 9 forms in Chapter III.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

In its 2009 resource planning work, FPL used the following financial assumptions: (i) a capital structure of 44.2% debt and 55.8% equity; (ii) a 7.03% cost of debt; (iii) a 12.5% return on equity; and (iv) an after-tax discount rate of 8.89%. In this work, FPL performed no sensitivity analyses that used varying financial assumptions.

In its new resource planning analysis work in 2010, financial assumptions such as these will change due to the outcome of FPL's recent base rate case.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). As discussed in response to Discussion Item # 2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective are identical when DSM levels are unchanged between competing plans. Therefore, in planning work in which DSM levels were unchanged, the equivalent cumulative present value of revenue requirements perspective was utilized.

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two system reliability criteria in its resource planning work that addresses generation, purchase, and DSM options. One of these is a minimum 20% Summer and Winter reserve margin. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability analysis work, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the Reliability Standards established by the North American Electric Reliability Council (NERC). The *NERC Reliability Standards* are available on the internet site (http://www.nerc.com/).

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Facility Rating Methodology* document that are also available on the internet under the FPL OATT Documents directory at https://www.oatioasis.com/FPL/index.html.

Generally, FPL limits its transmission facilities to 100% of the applicable thermal rating. The normal and contingency voltage criteria for FPL stations are provided below:

	Normal/Contingency	
Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95/0.95	1.05/1.07
230	0.95/0.95	1.06/1.07
500	0.95/0.95	1.07/1.09
Turkey Point (*)	1.01/1.01	1.06/1.06
St. Lucie (*)	1.00/1.00	1.06/1.06

(*) Voltage range criteria for FPL's Nuclear Power Plants

There may be isolated cases for which FPL may have determined that it is acceptable to deviate from the general criteria stated above. There are several factors that could influence this criteria, such as the overall number of potential customers that may be impacted, the probability of an outage actually occurring, or transmission system performance, as well as others.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM programs on demand and energy consumption is revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

The Executive Summary chapter provides a discussion of two system concerns that are typically addressed in FPL's resource planning work: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida. In addition, two other relatively recent items will also influence FPL's resource planning efforts. One of these items is the Executive Orders directive issued in 2007 by Governor Crist calling for reduction in greenhouse gas emissions and greater contribution from renewable energy sources. As previously discussed in both the Executive Summary chapter and Chapter III, FPL's resource planning has already taken positive steps in regard to both of these issues. The other item that could affect FPL's resource planning is the possibility of the establishment of a Florida standard for renewable energy, or clean energy, contributions to a utility system. A Renewable Portfolio Standard (RPS) proposal was prepared by the FPSC, and then sent to the Florida Legislature for consideration, with a possible change to a Clean Portfolio Standard (CPS), during the 2009 legislative session. However, no RPS or CPS legislation was enacted during the 2009 legislative session. RPS or CPS legislation, or other legislative initiatives regarding renewable or clean energy contributions, may occur in the future. If such legislation is enacted in 2010 or later years, FPL will then determine what steps need to be taken to address the legislation. Such steps would then be discussed in FPL's Site Plan in the year following the enactment of such legislation.

In addition to these system concerns/issues, there are other strategic factors FPL typically considers when choosing between resource options. These include the following: (1) technology risk; (2) environmental risk, and (3) site feasibility. The consideration of these factors may include both economic and non-economic aspects.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology, which has not achieved general commercial acceptance, has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts on the FPL system, including environmental compliance costs. Technologies regarded as more acceptable from an environmental perspective for a plan are those which minimize environmental impacts for the FPL system as a whole through highly efficient fuel use and state of the art controls.

Site feasibility assesses a wide range of economic, regulatory, and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed in prior FPL Site Plans, elements of FPL's recent and future capacity additions include the construction of new generating capacity at the West County Energy Center (WCEC) site, WCEC Units 1, 2, & 3. These generation construction projects were selected after evaluating competing bids received in response to Requests for Proposals (RFP) issued by FPL. The FPSC subsequently approved FPL's decision to construct these new combined cycle (CC) units in Determination of Need dockets.

In regard to the Modernization projects at FPL's existing Cape Canaveral and Riviera plants, these projects were also evaluated using the competing bids received in response to the RFP issued for WCEC Unit 3. In addition, bids from competing vendors were also evaluated for FPL's new solar thermal and PV projects.

The nuclear capacity additions, both the nuclear uprates and the new nuclear units, do not lend themselves to an RFP approach involving bids from third parties who would build new nuclear generation capacity. In addition, nuclear capacity additions are exempted from the Commission's Bid Rule by section 403.519 (4) (c). For these nuclear projects, FPL's procurement activities were conducted to ensure the best combination of quality and cost for the delivered products.

Construction capacity addition decisions for non-nuclear generation for years beyond those presented in this document are expected to be conducted in a manner consistent with the Commission's Bid Rule.

Identification of self-build options, beyond those units already approved by the FPSC and Governor and Siting Board or units for which FPL may be then seeking approval, in future FPL Site Plans will not be an indication that FPL has pre-judged any capacity solicitation it may conduct. The identification of future generating units is required of FPL in its Site Plan filings and represents those alternatives that appear to be FPL's best, most cost-effective self-build options at the time. FPL reserves the right to refine its planning analyses and to identify other self-build options. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an RFP is issued for Supply options, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

(1) FPL has identified the need for a new 230kV transmission line that required certification under the Transmission Line Siting Act which was issued in April 2006. The new line is to be completed in two phases connecting FPL's St. Johns Substation to FPL's Pringle Substation (also shown on Table III.E.1 in Chapter III). Phase 1 was completed in May 2009 and consisted of a new line connecting Pringle

to a new Pellicer Substation. Phase 2 is planned to connect St. Johns to Pellicer and is scheduled to be complete by December 2013. The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

(2) FPL has identified the need for a new 230kV transmission line (by December 2012) that required certification under the Transmission Line Siting Act which was issued on November 2008. The new line will connect FPL's Manatee Substation to FPL's proposed BobWhite Substation (also shown on Table III.E.1 in Chapter III). The construction of this line is necessary to serve existing and future customers in the Manatee and Sarasota areas in a reliable and effective manner.

Re: Docket No. 100000; Corrections to FPL's Ten Year Power Plant Site Plan

Dear Ms. Cole:

Please find enclosed an original and 25 copies of three replacement pages for FPL's 2010-2019 Ten Year Power Plant Site Plan, originally filed on April 1, 2010, reflecting corrected information. Revisions are in bold, red font.

Specifically, pages 45, 46, and 47 are being replaced and contain the following corrections:

- Page 45 – Schedule 3.1: Residential Load Management and Conservation and C/I Load Management and Conservation values for years 2010 – 2019 were corrected and the footnote for Cols (5) – (9) was revised.
- Page 46 – Schedule 3. 2: Residential Load Management and Conservation and C/I Load Management and Conservation values for years 2010 – 2019 were corrected and the footnote for Cols (5) – (9) was revised.
- Page 47 – Schedule 3.3: Historical Actual Total Billed Retail Energy Sales (GWh) and the Load Factor (%) for 2009 were corrected; Residential Conservation and C/I Conservation GWh values for years 2010 – 2019 were corrected; and the footnote for Projected Values Cols (3) and (4) was revised.

Please contact me if you or your Staff have any questions regarding this filing.

Sincerely,

Jessica Cano

Jessica Cano

Historical Values (2000 - 2009):

Col. (2) - Col. (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 2000 through 2009 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values **except for 2009 values which are August values.**
Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC), CILC and Commercial /Industrial Demand Reduction (CDR).

Col. (11) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (11) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8).

Projected Values (2010 - 2019):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation, cumulative load management, or **incremental load management.**

Col. (5) - Col. (9) represent **cumulative** load management, and incremental **conservation and** load management. **All** values are projected August values. **The 2010 values are based on IRP projections through the end of 2009 and FPL's new DSM Goals for 2010. In the projections for 2011 through 2019, FPL used cumulative values from the new DSM Goals with estimated breakouts into the residential, C/I, load management, and conservation categories.**

Col (8) represents FPL's Business On Call, CDR,CILC, and Curtailable programs/rates.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

2008	18,055	163	17,892	0	879	644	635	279	16,541
2009	20,081	162	19,919	0	951	678	764	295	18,366
2010	20,550	376	20,174	0	937	72	767	41	18,733
2011	20,647	381	20,266	0	943	87	774	55	18,788
2012	20,861	386	20,475	0	949	107	783	72	18,949
2013	21,138	392	20,746	0	957	131	793	93	19,163
2014	22,152	1,060	21,092	0	966	157	805	116	20,108
2015	22,745	1,284	21,461	0	975	185	817	141	20,627
2016	23,118	1,311	21,807	0	984	212	829	164	20,929
2017	23,488	1,341	22,147	0	993	237	840	186	21,232
2018	23,889	1,374	22,514	0	1,000	260	850	206	21,573
2019	24,293	1,409	22,884	0	1,007	281	859	225	21,921

Historical Values (2000 - 2009):

Col. (2) - Col. (4) are actual values for historical winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 2000 through 2009 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC), CILC and Commercial /Industrial Demand Reduction (CDR).

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (11) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8) - Col.(9).

Projected Values (2010 - 2019):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2010 are incorporated into the load forecast.

Col. (5) - Col. (9) represent **cumulative** load management, and incremental **conservation and** load management. **All** values are projected August values. **The 2010 values are based on IRP projections through the end of 2009 and FPL's new DSM Goals for 2010. In the projections for 2011 through 2019, FPL used cumulative values from the new DSM Goals with estimated breakouts into the residential, C/I, load management, and conservation categories.**

Col (8) represents FPL's Business On Call, CDR,CILC, and Curtailable programs/rates.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

2002	107,755	1,917	1,639	104,199	1,233	7,443	95,523	61.9%
2003	112,160	2,008	1,759	108,393	1,511	7,386	99,496	62.9%
2004	112,034	2,106	1,834	108,093	1,531	7,467	99,095	59.9%
2005	115,440	2,205	1,934	111,301	1,506	7,498	102,296	56.8%
2006	117,490	2,312	2,041	113,137	1,569	7,909	103,659	59.2%
2007	118,894	2,373	2,206	114,315	1,499	7,401	105,415	59.4%
2008	115,755	2,485	2,267	111,004	993	7,092	102,919	60.0%
2009	116,221	2,581	2,336	111,304	1,155	7,394	102,755	56.8%

Historical Values (2000 - 2009):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: Col. (2) = Col. (3) + Col. (4) + Col. (5).

Col.(3) & Col.(4) for 2000 through 2009 are DSM values starting in January 1988 and are annual (12-month) values. Col. (3) and Col. (4) for 2009 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWh reductions actually experienced each year .

Col. (5) is the **actual** Net Energy for Load (NEL) for years 2000 - 2009.

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (5) - Col. (6) - Col. (7). These values are at the meter.

Col. (9) is calculated using Col. (5) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (5)*1000) / ((Col.(2) * 8760) Adjustments are made for leap years.

Forecast of Annual Net Energy for Load - GWh: Base Case
(All values are "at the generator"values except for Col (8))

(1) Year	(2) **Forecasted** Net Energy For Load without DSM	(3) Residential Conservation	(4) C/I Conservation	(5) = (2) - (3) - (4) Net Energy For Load Adjusted for DSM	(6) Sales for Resale GWh	(7) Utility Use & Losses	(8) = (2) - (6) - (7) **Forecasted** Total Billed Retail Energy Sales (GWh) without DSM	(9) Load Factor(%)
2010	109,886	61	41	109,784	2,046	7,172	100,668	57.2%
2011	111,634	211	141	111,282	2,145	7,150	102,340	58.5%
2012	113,516	408	272	112,837	2,166	7,372	103,979	58.4%
2013	115,899	633	422	114,845	2,059	7,493	106,347	59.2%
2014	122,471	868	579	121,025	4,846	8,068	109,558	59.3%
2015	124,742	1,094	729	122,918	5,484	7,980	111,278	59.5%
2016	125,672	1,298	865	123,510	5,513	8,070	112,089	58.8%
2017	127,236	1,477	984	124,775	5,555	8,173	113,508	58.6%
2018	129,665	1,636	1,091	126,938	5,602	8,370	115,693	58.4%
2019	131,712	1,781	1,187	128,744	5,648	8,468	117,596	58.3%

Projected Values (2010 - 2019):

Col. (2) represents Forecasted Net Energy for Load w/o DSM values. The values are extracted from Schedule 2.3, Col. (19).

Col. (3) & Col. (4) are forecasted values of the reduction on sales from incremental conservation and are mid-year (6-month) values **reflecting DSM signups occurring evenly thoughout each year.**
The effects of conservation implemented prior to 2010 are incorporated into the load forecast.

Col. (5) is the forecasted Net Energy for Load (NEL) after adjusting for DSM impacts DSM for years 2010 - 2019. Col.(5) = Col.(2) - Col.(3) - Col.(4)

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (2) - Col. (6) - Col. (7). These values are at the meter.

Col. (9) is calculated using Col. (2) from this page and Col. (2), "Total", from Schedule 3.1. Col. (9) = ((Col. (2)*1000) / ((Col. (2) * 8760) Adjustments are made for leap years.

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan. This plan should include an estimate of the utility's future electric power generating needs, a projection of how these estimated generating needs might be met, and disclosure of information pertaining to the utility's preferred and potential power plant sites. The information contained in this Site Plan is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (F.A.C.).

This Ten Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2010 and that were on-going in the first Quarter of 2011. The forecasted information presented in this plan addresses the years 2011 through 2020.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information and all of this information is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings, at the appropriate time.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, based on FPL's IRP work in 2010 and

early 2011.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as Preferred and Potential site locations for additional electric generation facilities.

Chapter V – *Other Planning Assumptions and Information*

This chapter addresses twelve "discussion items" which pertain to additional information that is included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2011 Ten Year Power Plant Site Plan (Site Plan) presents FPL's current plans to augment and enhance its electric generation capability (owned or purchased) as part of its efforts to meet its projected incremental resource needs for the 2011 - 2020 time period. By design, the primary focus of this document is on supply side additions; i.e., electric generation capability and the sites for these additions. The supply side additions discussed in this document are resources projected to be needed after accounting for FPL's demand side management (DSM) efforts and the significant energy efficiency contributions from the current federal appliance and lighting efficiency standards. The projected impacts of the federal appliance and lighting efficiency standards are already reflected in FPL's load forecast which is discussed in Chapter II. The projected impacts of FPL's DSM efforts are addressed as projected reductions to the forecasted load.

The resource plan that is presented in FPL's 2011 Site Plan contains a number of key similarities to the resource plan presented in FPL's 2010 Site Plan. On the other hand, there are specific factors that are driving changes in FPL's resource plans and which will continue to influence FPL's on-going resource planning work. A brief discussion of these similarities, factors, and changes is provided below. Additional information regarding many of these topics is presented in Chapter III.

I. Similarities to the Resource Plan Previously Presented in FPL's 2010 Site Plan:

There are six key similarities in the current resource plan presented in this document compared to the resource plan presented in the 2010 Site Plan.

Similarity # 1: A third highly efficient combined cycle (CC) generating unit at the West County Energy Center site will be added to FPL's system in 2011.

One similarity to FPL's 2010 Site Plan is the addition of a third new highly efficient natural gas-fired CC generating unit at FPL's West County Energy Center (WCEC) site in 2011. FPL placed in-service two 1,219 MW (Summer) CC units at the WCEC site in 2009. These units are identified as WCEC Units 1 and 2. The WCEC Units 1 and 2 were approved by the Florida Public Service Commission (FPSC) in June 2006 in Order No. PSC-06-0555-FOF-EI. Site Certification for these units under the Florida Electric Power Plant Siting Act was approved by the Governor and the Cabinet serving as the Siting Board in December 2006 in Order No. DEP 06-1755.

FPL is currently constructing the third new CC unit, WCEC Unit 3, at this site. This new CC unit is projected to go into commercial operation by June 2011. The WCEC Unit 3 was approved by the FPSC in September 2008 in Order No. PSC-08-0591-FOF-EI and Site Certification for this unit was obtained in November 2008 in Order No. DEP 08-1204.

Similarity # 2: FPL's 2011 Site Plan continues to project that the DSM Goals imposed by FPSC for FPL will be met.

In late 2009, the FPSC imposed new DSM Goals for FPL for the years 2010 through 2019. As was the case in its 2010 Site Plan, FPL continues to project that these DSM Goals will be met.

However, there are several aspects of the new DSM Goals that are cause for concern. One issue is that, in imposing DSM Goals for FPL, the approach used by the FPSC in 2009 deviated from prior practice in ways that resulted in electric rates for FPL's customers being higher than would otherwise have been the case. In addition, this high level of DSM Goals means that FPL is becoming increasingly dependent upon DSM resources for reserves needed to maintain system reliability. This concern is mentioned again later in this Executive Summary and is discussed in more detail in Chapter III.

Similarity # 3: Generating capacity at FPL's four existing nuclear generation units will increase in the 2011 – 2013 time frame.

FPL will be adding approximately 450 MW of increased generating capacity from its existing Turkey Point and St. Lucie nuclear power plants. This increased capacity is currently scheduled to come in-service between March 2011 and January 2013. The need for these nuclear capacity "uprates" was approved by the FPSC in January 2008 in Order No. PSC-08-0021-FOF-EI. The Final Order for the Site Certification was issued in September 2008 for the St. Lucie uprates in Order No. DEP 08-0942 and in October 2008 for the Turkey Point uprates in Order No. DEP 08-1141. (There are some relatively small changes in the schedules for the increased nuclear capacity that are discussed in Chapter III.)

Similarity # 4: FPL continues to pursue licenses, permits, and approvals that would be necessary for future construction and operation of two new nuclear generating units at its Turkey Point site.

FPL is continuing its work to obtain all of the licenses, permits, and approvals that would be necessary to construct and operate two new nuclear units at its Turkey Point site in the future.

These licenses, permits, and approvals will provide FPL with the option to construct these nuclear units at Turkey Point for a time expected to be up to 20 years from the time the licenses and permits are granted, and then to operate the units. A decision regarding construction of these new units will be made once the licenses and permits are granted. (Based on the current estimated time for construction, the earliest practical deployment dates for the two new units would be beyond the 10-year reporting period for this Site Plan. Therefore, these units are not shown in this document.)

Similarity # 5: A number of existing generating units have been placed on Inactive Reserve.

In 2009, FPL began to take a number of its existing generating units out of active service and place them on Inactive Reserve status. That process is continuing in early 2011. The specific generating units that have been placed on Inactive Reserve status are discussed in Chapter III of this document. However, there are changes in regard to FPL's current plans for these units that are discussed later in this Executive Summary and in more detail in Chapter III.

Similarity # 6: The modernizations of FPL's existing Cape Canaveral and Riviera plant sites is underway and are projected to be completed in 2013 and 2014, respectively.

FPL's 2010 Site Plan projected that the modernizations of FPL existing generating units at these two sites would occur in 2013 (Cape Canaveral) and 2014 (Riviera). FPL received need determination approval from the FPSC for both of these modernizations in September 2008 in Order No. PSC-08-0591-FOF-EI. Site Certification was received for Cape Canaveral in October 2009 in Order No. DEP 09-1015. , Site Certification was received for Riviera in November 2009 in Order No. DEP O9-1245. These modernizations are underway and are again reflected in this Site Plan.

II. Factors That Are Driving Changes in FPL's Resource Plan:

There are two primary factors that are driving the changes in FPL's 2011 resource plan compared to the resource plan presented in FPL's 2010 Site Plan. These factors, and their impacts on the resource plan, are summarized below and are addressed in more detail in Chapter III of this document.

Factor # 1: The costs of returning units from Inactive Reserve status are projected to be high.

Recent detailed evaluation of the specific costs of returning generating units from their current Inactive Reserve status, and then operating those units after they are returned to service, indicate that such costs are projected to be high. These cost projections require further analysis to determine when, and if, these units will be returned to active service.

Factor # 2: The growing number of combined cycle units on FPL's system will require that planned maintenance outages for FPL's fleet of fossil-fueled generating units be scheduled throughout the year, including Summer and Winter peak load months .

Combined cycle units are based on advanced combustion turbines whose planned maintenance outages must be strictly tied to their operating hours. Therefore, there is relatively little flexibility regarding when planned maintenance for the combined cycle units can be scheduled. This makes it more difficult to schedule planned maintenance for these units, plus all of FPL's other fossil-fueled generating units, solely in non-peak load months.

III. Resulting Changes in FPL's Resource Plan Compared to the Resource Plan Previously Presented in FPL's 2010 Site Plan:

The combined effect of the factors discussed above contribute to three significant changes in FPL's resource plan presented in this document compared to the resource plan previously presented in FPL's 2010 Site Plan. The changes are summarized below and are discussed in more detail in Chapter III.

Resulting Change # 1: FPL's 2011 Site Plan does not specify a permanent return to active service of the existing generating units placed in Inactive Reserve.

The effect of the projected high costs of returning these units to active status, and subsequently operating these units, are reflected in the resource plan that FPL presents in its 2011 Site Plan. Based on these cost projections, and the comparatively lower projected system costs of new combined cycle capacity, this resource plan does not show the permanent return to service of any of these generating units in the ten-year period addressed in this document.

FPL currently expects that three of these generating units, Cutler 5 & 6 and Sanford 3, will be retired by 2012. FPL will be examining other potential uses for these sites, including their potential use as sites for new renewable energy facilities. The four steam units at FPL's Port Everglades site will remain available to return to service at least until 2014. Two of these four steam units, Port Everglades Units 3 & 4, are currently scheduled to be returned to active service in 2012 and then return to Inactive Reserve status at least until the "modernized" units at Cape Canaveral and Riviera are in normal operation (i.e., until mid-2014). The other two steam units, Port Everglades Units 1 & 2, are currently scheduled to remain on Inactive Reserve status during this time period. The remaining unit on Inactive Reserve status, Turkey Point 2, will remain on Inactive Reserve status, but will operate as a synchronous condenser (which provides reactive power support for FPL's transmission system in Southeastern Florida) rather than as provider of electricity. This unit is capable of returning to active service in the future to provide MW and MWh. (Further discussion of the units on Inactive Reserve status is provided in Chapter III.)

FPL will continue to evaluate the relative economics of returning the Port Everglades and Turkey Point 2 units from Inactive Reserve compared to adding new combined cycle capacity at Greenfield/Brownfield sites and/or modernizing generation facilities at existing sites.

Resulting Change # 2: For planning purposes consistent with the objectives of this reporting document, the resource plan presented in this Site Plan shows the addition of two new Greenfield CC units.

With the assumption that none of the units currently in Inactive Reserve status will be permanently returned to active service during the ten-year period addressed in this document, and consistent with all other assumptions (new load forecast, DSM Goals, etc.), FPL currently projects that it will have its next resource need in 2016. Consistent with two of the objectives of this document, which are to provide a preview of what types of generating units FPL projects would be added, and when FPL projects that those additions would be made, FPL is projecting that this resource need would be met by the addition of one new CC unit similar to the new CC units being added as part of the modernizations of the Cape Canaveral and Riviera sites. An additional resource need is then projected by the year 2020. For planning purposes, FPL currently projects that this subsequent resource need would also be met by the addition of another new CC unit of the same type. No specific sites have been designated for these two new CC units and they are referred to as Greenfield CC units throughout this document.

As previously mentioned, and as part of FPL's ongoing resource planning process, FPL will continue to evaluate how best to meet future resource needs; i.e., through new CC capacity and/or the return of Inactive Reserve units to active service. These analyses will also examine the potential for modernizing additional existing power plants such as is being done at the Cape

Canaveral and Riviera sites. For example, the existing Port Everglades site is a potential site for modernization. Other existing sites may also emerge in the ongoing analyses as potential candidates for modernization. Analyses of any modernization candidates would include evaluation of numerous factors including: fuel delivery costs/issues, transmission impacts (especially in the Southeastern region of Florida as will be discussed later), system reliability issues due to the removal of existing units from active service prior to the construction of new capacity at the site, overall system economics, etc.

Resulting Change # 3: *FPL's resource plan reflects that planned maintenance must be scheduled during Summer and Winter peak months.*

Due to the previously discussed requirement that combustion turbine maintenance take place on a strict schedule based on operating hours, FPL must schedule planned maintenance during peak load months. This is reflected in this Site Plan as MWs of capacity that are projected to be out-of-service in Summer and Winter reserve margin calculations (as presented in Schedules 7.1 through 7.4 in Chapter III.) One effect of this change is that it increases FPL's projected resource needs in future years.

IV. Additional Factors Influencing FPL's Resource Planning Work:

In addition to the two factors specifically described above (projected high costs of returning units in Inactive Reserve to active service and the need to schedule planned maintenance in peak load months) that are driving changes in FPL's resource plans, there are additional factors that also influence FPL's resource planning work. Among these other additional factors are two that FPL typically refers to as on-going system concerns that FPL has considered in its resource planning work for a number of years. These two on-going system concerns are: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida, particularly in Miami-Dade and Broward counties.

A third factor that could affect FPL's resource planning is the possibility of the establishment of a Florida standard for renewable energy or clean energy. A Renewable Portfolio Standard (RPS) proposal was prepared by the FPSC, and then sent to the Florida Legislature for consideration, with a possible change to a Clean Portfolio Standard (CPS), during the 2009 legislative session. However, no RPS or CPS legislation was enacted during the 2009 or 2010 legislative sessions. RPS or CPS legislation, or other legislative initiatives regarding renewable or clean energy contributions, may occur in the future. If such legislation is enacted during 2011 or in later years, FPL will then determine what steps need to be taken to address the legislation. Such steps would then be discussed in FPL's Site Plan in the year following the enactment of such legislation.

A fourth factor that will affect FPL's resource planning is the issue of how best to reliably obtain additional natural gas for FPL's system which is projected to continue to add more natural gas-fired generating capacity after the modernizations of Cape Canaveral and Riviera are completed.

A fifth factor or issue that will affect FPL's resource planning was previously mentioned in this Executive Summary: the extent to which FPL's reserves will become increasingly dependent upon DSM resources as opposed to generation resources. This projected imbalance in future reserves is becoming more pronounced, in part, because of higher DSM Goals requirements.

Each of these factors will continue to be examined in FPL's on-going resource planning work during the rest of 2011 and in future years.

Table ES-1 presents a current projection of major changes to specific generating units and firm capacity purchases for 2011 – 2020 in terms of Summer MW. Table ES-2 then expands upon the information presented in Table ES-1 by adding projections of Winter MW impacts, Summer reserve margins, Winter reserve margins, etc. (Although neither table specifically identifies the impacts of the new DSM Goals on FPL's resource needs and resource plan, the DSM Goals have been fully accounted for in the resource plan presented in this Site Plan.)

Table ES-1: Projected Capacity & Firm Purchase Power Changes

*Year **	*Projected Capacity & Firm Purchase Power Changes*	*Summer MW*	*Date*
2011	Riviera Unit 3 & 4 - removed for modernization	(565)	February-11
	St. Lucie Unit 2 Uprates - interim increase	17	April-11
	West County Unit # 3	1,219	June-11
	Total of MW changes to Summer reserve margin:	**671**	
2012	Inactive Reserve Unit (PE Units 3 & 4) - active service	761	January-12

2020	Greenfield 3x1 Combined Cycle (6)	—	1,191	30.4%	23.1%

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) The Summer and Winter reserve margins reflect an additional 350 MW in summer and 550 MW in winter of units scheduled to be out during those peak periods. Saa Section III.C.1 in Chapter 3 for more details.
(3) Winter values are forecasted values for January of the year shown.
(4) Summer values are forecasted values for August of the year shown.
(5) These are firm capacity and energy contracts with QF, utilities, and other entities. See Table I.B.1 and Table I.B.2 for more details.
(6) All new unit additions are scheduled to be in-service in June of the year shown. All additions assumed to start in June are included in the Summer reserve margin calculation starting in that year and in the Winter reserve margin calculation starting with the next year.
(7) Outages for uprate work.
(8) Outages for ESP work.
(9) A number of existing FPL power plants have been removed from service and placed on Inactive Reserve status. See Chapter 3 for a discussion of the units on Inactive Reserves.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.7 million people. FPL served an average of 4,520,328 customer accounts in thirty-five counties during 2010. These customers were served from a variety of resources including: FPL-owned fossil-fueled, renewable, and nuclear generating units, non-utility owned generation, demand side management (DSM), and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at sixteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, Florida. The current electrical generating facilities consist of four nuclear units, three coal units, fourteen combined cycle (CC) units, fifteen fossil steam units, forty-eight combustion gas turbines, one simple cycle combustion turbine, and two photovoltaic facilities[1]. The locations of these eighty-seven generating units are shown on Figure I.A.1 and in Table I.A.1. Table I.A.2 provides a "break down" of the capacity provided by the combustion turbine (CT) and steam turbine (ST) components of FPL's existing CC units.

FPL's bulk transmission system is comprised of 6,721 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 586 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

[1] FPL also has one 75 MW solar thermal facility at its Martin plant site. This facility does not generate electricity as the other units mentioned above do. Instead, it produces steam that reduces the use of fossil fuel to produce steam.

FPL Generating Resources by Location

Location/ Map Key	Plant Name	Number of Units	Summer MW
A	Turkey Point	5	3,322
B	St. Lucie *	2	1,553

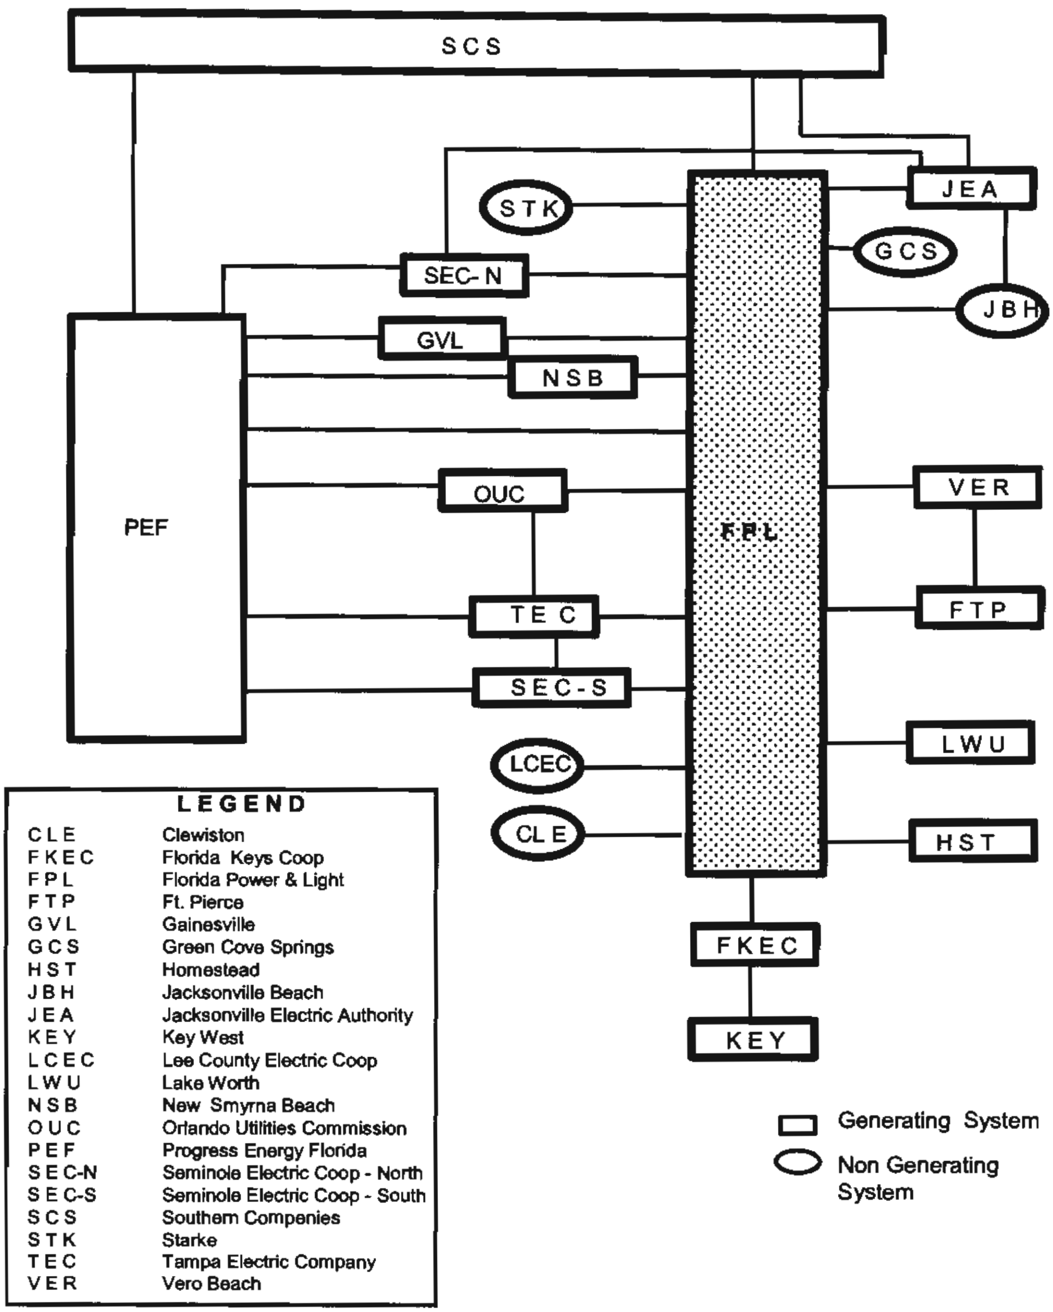

Figure I.A.3: FPL Interconnection Diagram

I.B Firm Capacity Power Purchases

Purchases from Qualifying Facilities (QF):

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five qualifying facilities; i.e., cogeneration/small power production facilities, to purchase firm capacity and energy as shown in Table I.A.2, Table I.B.1, and I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Purchases from Utilities:

FPL has a Unit Power Sales (UPS) contract to purchase 931 MW from the Southern Company (Southern) through the end of December 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 375 MW (Summer) and 383 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. However, due to Internal Revenue Service (IRS) regulations, the total amount of energy that FPL may receive from this purchase is limited. FPL currently assumes, for planning purposes, that this limit will be reached in the first half of 2016. Once this limit is reached, FPL will be unable to receive firm capacity and energy from these purchases. (However, FPL will continue to receive firm capacity and energy from its ownership portion of the SJRPP units.)

These purchases are shown in Table I.A.3, Table I.B.1, and Table I.B.2. FPL also has ownership interest in the SJRPP units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.

Other Purchases:

FPL has another firm capacity purchase contract with a non-QF, non-utility supplier. This purchase contract runs through May 2012. Table I.B.1 and I.B.2 present the Summer and Winter MW, respectively, resulting from this contract.

Table I.B.1: FPL's Firm Purchased Power Summer MW

Summary of FPL's Firm Capacity Purchases: Summer MW (for August of Year Shown)

I.C Non-Firm (As Available) Energy Purchases

FPL purchases non-firm (as-available) energy from several cogeneration and small power production facilities. Table I.C.1 shows the amount of energy purchased in 2010 from these facilities.

Table I.C.1: As-Available Energy Purchases From Non-Utility Generators in 2010

I.D. Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include a number of conservation/energy efficiency and load management initiatives. FPL's DSM efforts through 2010 have resulted in a cumulative Summer peak reduction of approximately 4,371 MW at the generator and an estimated cumulative energy saving of approximately 55,462 Gigawatt-hour (GWh) at the generator. After accounting for reserve margin requirements, FPL's DSM efforts through 2010 have eliminated the need to construct the equivalent of more than 13 new 400 MW generating units. DSM is discussed further in Chapter III.

1/ These ratings are peak capability.
2/ The Cape Canaveral modernization project has resulted in the removal of the two steam units previously at the Canaveral site to clear the site for the introduction of a new combined cycle generating unit. This new unit is projected to go into service in June 2013.
3/ These generating units were on Inactive Reserve status as of 12/31/2010.
4/ The capacity shown for the PV facility at DeSoto is considered as non-firm generating capacity due to the intermittent nature of the solar resource.
5/ Martin 8 is also partially fueled by a 75 MW solar thermal facitility that supplies steam when adequate sunlight is available, thus reducing fossil fuel use.

System Firm Generating Capacity as of December 31, 2010 [6/] =												24,762	23,687

1/ These ratings are peak capability.

2/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Unit No. 1 and No. 2, excluding the Jacksonville Electric Authority (JEA) share of 80%.

3/ Total capability of each unit is 853/839 MW. FPL's ownership share of St. Lucie 1 and 2 is 100%(853/839) and 85% (714/726) respectively as shown above. FPL's share of the deliverable capacity from each unit is approx. 92.5% and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit.

4/ This generating unit was on Inactive Reserve status as of 12/31/2010.

5/ The Total System Generating Cpacity value shown includes FPL-owned firm and non-firm generating capacity.

6/ The System Firm Generating Capacity value shown includes only firm generating capacity.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

II. A. Overview of the Load Forecasting Process

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are typically developed on an annual basis for resource planning work at FPL. New long-term forecasts were developed by FPL in early 2011 that replaced the previous long-term load forecasts that were used by FPL during 2010 in much of its resource planning work and which were presented in FPL's 2010 Site Plan. These new load forecasts are utilized throughout FPL's 2011 Site Plan. These forecasts are a key input to the models used to develop FPL's integrated resource plan.

The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads. Consistent with past forecasts, the primary drivers to develop these forecasts include economic conditions and weather.

The projections for the national and Florida economies are obtained from the consulting firm IHS Global Insight. Population projections are obtained from the Florida Legislature's Office of Economic and Demographic Research (EDR). These projections are developed, in conjunction with the Bureau of Economic and Business Research (BEBR) of the University of Florida. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects FPL's energy sales and peak demand. Two sets of weather variables are developed and used in FPL's forecasting models:

1. Cooling and Heating Degree-Hours are used to forecast energy sales.
2. Temperature data, along with Cooling and Heating Degree-Hours, are used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Hours are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. A composite hourly temperature profile is derived using hourly temperatures across FPL's service territory. Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained. In developing the composite hourly profile, these regional temperatures are weighted by regional energy sales. This composite temperature is used to derive projected Cooling and Heating Degree-Hours, which are based on starting point temperatures of 72° F and 66° F degrees, respectively.

Similarly, composite temperature and hourly profiles of temperatures are used for the Summer and Winter peak models.

II. B. Comparison of FPL's Current and Previous Load Forecasts

FPL's current load forecast is generally in line with the load forecast presented in its 2010 Site Plan. There are three primary factors that are driving the current load forecast: projected population growth, a projection of gradual recovery following the economic recession in Florida, and a somewhat lower projected long-term price of electricity. The net impact of these three factors is that the current load forecast is similar to the 2010 Site Plan forecast in most years between 2011 and 2020.

The customer forecast is based on recent population projections. Population projections are derived from the EDR's February 2011 Demographic Estimating Conference. This forecast is slightly higher than the prior projection. During the recent recession, net migration into Florida fell to record lows. Historically low rates of net migration are expected to continue until around 2012 - 2013 due to the weakened housing market and other lingering effects from the recession which make it difficult for people to relocate.

As population growth recovers, a modest rebound in customer growth is projected in 2012 and 2013. However, population growth is not expected to reach the level historically experienced in Florida until 2014 - 2015. As a result of the higher than expected customer growth in 2010, the total number of customers projected in the current load forecast is above the levels projected in FPL's 2010 Site Plan.

Consistent with the economic assumptions incorporated into the 2010 Site Plan, the state's economy continues to suffer the lingering effects of an economic recession. Beginning in mid-2010, Florida began seeing an annual increase in employment for the first time in three years. Since December 2009, Florida has gained nearly 44,000 jobs. However, Florida is still a long way from recovering. Since the recession began, Florida had lost over 800,000 jobs. Foreclosures are still a problem for the state, with Florida being second only to California in the number of mortgage foreclosures. The severity of the recession and current economic conditions suggests that Florida's economic recovery will be gradual. By 2013, the state's economy is projected to resume a more historically typical rate of growth. The real price of electricity in the current forecast is somewhat lower than that utilized in last year's Site Plan. A delay in carbon pricing, combined with lower projected fuel costs, are two factors driving the relatively lower forecasted price of electricity.

Consistent with the forecast presented in FPL's 2010 Site Plan, the total growth projected for the ten-year reporting period of this document is significant. The Summer peak is projected to increase to 26,193 MW by 2020, an increase of 3,937 MW over the 2010 actual Summer peak. Likewise, NEL is projected to reach 133,121 GWH in 2020, an increase of 18,747 GWH from the actual 2010 value.

II.C. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class and are adjusted to match the NEL forecast. The results of these sales forecasts for the years 2011 - 2020 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and NEL forecast are outlined below.

1. Residential Sales

Residential electric usage per customer is estimated by using an econometric model. Residential sales are a function of: Cooling Degree-Hours, Heating Degree-Hours, lagged Cooling Degree-Hours, lagged Heating Degree-Hours, consecutive minimum temperature days square, real price of electricity (a 12-month moving average), Florida real per capita income, a variable designed to reflect the impact of empty homes, and a dummy variable for the month of January. The impact of weather is captured by the Cooling Degree-Hours, Heating Degree-Hours, the one month lag of these variables, and the consecutive minimum temperature variable. The price of electricity plays a role in explaining electric usage, because electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. To capture economic conditions, the model includes Florida's real per capita income. The housing crisis has also had an impact on use per customer. Consequently, the model includes a variable designed to capture the impact of empty homes. A dummy variable for January is included to reflect a different usage pattern for this month. Residential energy sales are forecasted by multiplying the residential use per customer forecast by the number of residential customers forecasted.

2. Commercial Sales

The commercial sales forecast is also developed using an econometric model. Commercial sales are a function of the following variables: Florida real per capita income, commercial real price of electricity, Cooling Degree-Hours, Heating Degree-Hours, lagged Cooling Degree-Hours, a variable designed to reflect the impact of empty homes, a dummy variable for the month of December and for the specific month of January 2007, and an autoregressive term. Cooling Degree-Hours, Heating Degree-Hours, and the one month lag of Cooling Degree-Hours are used to capture weather-sensitive load in the commercial sector.

3. Industrial Sales

The industrial class is comprised of two distinct groups; very small accounts (those with less than 20 kW of demand) and large, traditionally industrial customers. As such, the forecast is developed using a separate econometric model for each group of industrial customers. The small industrial sales model utilizes the following variables: Florida Housing Starts, Cooling Degree-Hours, Heating Degree-Hours, and an autoregressive term. The Cooling and Heating Degree-Hours are used to capture the weather-sensitive load in this group of industrial customers. Florida Housing Starts are reflective of construction activity which comprises a significant portion of this group. The large industrial sales model utilizes the following variables: Florida population, and the industrial real price of electricity (a 24-month moving average).

4. Railroad and Railways Sales and Street and Highway Sales

The projections for railroad and railways sales are based on historical average use per customer which is multiplied by the forecasted number of customers. This class consists solely of Miami-Dade County's Metrorail system.

The forecast for street and highway sales is developed by using a trended use per customer, which is multiplied by the number of forecasted customers.

5. Other Public Authority Sales

This revenue class is a closed class with no new customers being added. This class consists of sports fields and a government account. The forecast for this class is based on historical knowledge of its usage characteristics.

6. Total Sales to Ultimate Customer

Sales forecasts by revenue class are summed to produce a total sales forecast.

7. Sales for Resale

Sales for resale (wholesale) customers are composed of municipalities and/or electric co-operatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers. Currently there are four customers in this class: the Florida Keys Electric Cooperative; City of Key West; Metro-Dade County; and Lee County Electric Cooperative. In addition, FPL will begin making sales to Seminole Electric Cooperative in June 2014 under a long term agreement[2].

FPL provides service to the Florida Keys Electric Cooperative under a long-term partial requirements contract. The sales to Florida Keys Electric Cooperative are forecasted using a regression model.

FPL's sales to the City of Key West are expected to terminate in 2013. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor.

Metro-Dade County sells 60 MW to Progress Energy Florida. Line losses are billed to Metro-Dade under a wholesale contract.

Lee County has contracted with FPL for FPL to supply a portion of their load through 2013, then to begin serving their entire load beginning in 2014 through 2033. This contract began in January 2010. Forecasted sales to Lee County are based on assumptions regarding their contract demand and expected load factor.

A new contract with Seminole Electric Cooperative is included in the forecast which includes delivery of 200 MW beginning in June 2014.

II.D. Net Energy for Load (NEL)

An econometric model is developed to produce a NEL per customer forecast. The inputs to the model include the real price of electricity (a 12-month moving average), and Florida real per capita income. The model also includes three weather variables: Cooling Degree Hours using a base temperature of 72 degrees, Heating Degree Days using a base of 66 degrees, and an additional heating degree variable for extreme cold weather

[2] FPL is currently evaluating the possibility of serving the Vero Beach electrical load at the time the 2011 Site Plan is being prepared. Because this possibility is still being evaluated, the load forecast presented in this Site Plan does not include this potential load.

using a base of 45 degrees. In addition, the model also includes variables for mandated energy efficiency and a variable designed to capture the impact of empty homes. Seasonal dummy variables are included for the months of February, May, July, October, and December.

The mandated energy efficiency variables are included to capture the impacts of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and compact florescent light bulbs. The estimated impact of these factors for the 2011 to 2020 time period is a reduction, on average, of 10,447 GWh per year. The increase in the number of empty homes resulting from the current housing slump has affected use per customer and is captured in a separate variable. The forecast was also adjusted for additional load estimated from hybrid vehicles, beginning in 2010, which resulted in an increase of approximately 2,052 GWh by the end of the ten-year reporting period.

The NEL forecast is developed by multiplying the NEL per customer forecast by the total number of customers forecasted. Once the NEL forecast is obtained, total billed sales are computed using a historical ratio of sales to NEL. The sales by class forecasts previously discussed are then adjusted to match the total billed sales. The forecasted NEL values for 2011 - 2020 are presented in Schedule 3.3 that appears at the end of this chapter.

II.E. System Peak Forecasts

The rate of absolute growth in FPL system peak load has been a function of the size of the customer base, varying weather conditions, projected economic conditions, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient appliances and lighting. FPL developed the peak forecast models to capture these behavioral relationships. Impacts of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the impact of compact fluorescent light bulbs are taken into account in developing the peak forecast. The estimated impact of these federal mandates for the 2011 to 2020 time frame is a reduction of approximately 909 MW (Summer) and 454 MW (Winter) in 2011, and approximately 2,268 MW (Summer) and 1,315 MW (Winter) by 2020. The forecast was also adjusted for additional load estimated from hybrid vehicles which resulted in an increase of approximately 261 MW in the Summer and 114 MW in the Winter by the end of the ten-year reporting period.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2011 – 2020 are presented at the end of this chapter in Schedules 3.1 and 3.2, and in Chapter III in Schedules 7.1 through 7.4.

1. **System Summer Peak**

   The Summer peak forecast is developed using an econometric model. The variables included in the model are the real price of electricity, Florida real per capita income, Cooling Degree-Hours in the day prior to the peak, the maximum temperature on the day of the peak, and a variable for mandated energy efficiency. The model is based on the Summer peak contribution per customer and is, therefore, multiplied by total customers, and adjusted to account for incremental loads resulting from hybrid vehicles and new wholesale contracts, to derive FPL's system Summer peak.

2. **System Winter Peak**

   Like the system Summer peak model, this model is also an econometric model. The model consists of two weather-related variables: the minimum temperature on the peak day and Heating Degree-Hours for the prior day square. The model also includes a dummy variable for winter peaks occurring on weekends and an autoregressive term. The forecasted results are adjusted for the impact of mandated energy efficiency. The model is based on the Winter peak contribution per customer and is, therefore, multiplied by total customers, and adjusted to account for incremental loads resulting from hybrid vehicles and new wholesale contracts, to derive FPL's system Winter peak.

3. **Monthly Peak Forecasts**

   The forecasting process for monthly peaks consists of the following actions:

   a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to the appropriate seasonal peak.

   b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.F. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2011 - 2020 are produced using a System Load Forecasting "shaper" program. This model uses years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

II.G. Uncertainty

In order to address uncertainty in the forecasts of aggregate peak demand and NEL, FPL first evaluates the assumptions underlying the forecasts. FPL takes a series of steps in evaluating the input variables, including comparing projections from different sources, identifying outliers in the series, and assessing the series' consistency with past forecasts. In addition, FPL reviews factors which may affect the input variables. This may require reviewing data from local economic development boards or from FPL's own Customer Service Business Unit. Other factors which may be considered include demographic trends and housing characteristics such as starts, size, and vintage of homes.

Uncertainty is also addressed in the modeling process. Generally, econometric models are used to forecast the aggregate peak demand and NEL. During the modeling process, the relevant statistics (goodness of fit, F-statistic, P-values, mean absolute deviation (MAD), mean absolute percentage error (MAPE), etc.) are scrutinized to ensure that the models adequately explain historical variation. Once a forecast is developed, it is compared with past forecasts. Deviations from past forecasts are examined in light of changes in input assumption to ensure that the drivers underlying the forecast are well understood. Finally, forecasts of aggregate peak demand and NEL are compared with their actual values as they become available. An ongoing process of variance analyses is performed. To the extent that the variance analysis identifies large unexplained deviations between the forecast and actual values, revisions to the econometric model may be considered.

The inherent uncertainty in load forecasting is addressed in different ways in regard to FPL's overall resource planning and operational planning work. In regard to FPL's resource planning work, FPL's utilization of a 20% reserve margin criterion (approved by the FPSC) is designed, in part, to maintain reliable electric service to FPL's customers in light of forecasting uncertainty. In regard to operational planning, an extreme weather load forecast for the projected Summer peak day is produced based on maximum historical temperatures on the day of the Summer peak. Likewise, an extreme weather Winter peak forecast is developed by considering minimum historical temperatures at the time of the Winter peak. Statistical analysis on the distribution of historical weather data is performed to evaluate and understand the impact of extreme weather on the peaks and on NEL, and the likelihood of experiencing extreme weather.

II.H. DSM

The effects of FPL's DSM energy efficiency programs implementation through 2010 are assumed to be imbedded in the actual usage data for forecasting purposes. Any change in usage pattern, be it the impact of FPL's DSM energy efficiency efforts, price impact, or weather impact, is reflected in the actual observed load data. Therefore, energy efficiency impacts, whether market-driven or as a result of FPL's DSM programs, are assumed to be included in the historical usage data for peaks and NEL.

The impacts of incremental energy efficiency that FPL plans to implement in the future, plus the impacts of FPL's cumulative and incremental load management programs, are accounted for as "line item reductions" to the forecasts as part of the IRP process as shown in Schedules 7.1 and 7.2. After making these adjustments to the load forecasts, the resulting "firm" load forecast is then used in FPL's IRP work.

Schedule 2.1

2006	21,819	258	21,563	0	910	770	607	634	20,302
2007	21,962	261	21,701	0	941	608	676	672	20,345
2008	21,060	181	20,879	0	986	861	734	697	19,360
2009	22,351	249	22,102	0	976	902	760	719	20,595
2010	22,256	419	21,837	0	991	982	816	747	16,720

Historical Values (2001 - 2010):

Col. (2) - Col. (4) are actual values for historical Summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) represent ectual DSM capebilities starting from January 1988 end are ennuel (12-month) values except for 2010 values which are August values. Note thet the values for FPL's former Interruptible Rete are incorporated into Col. (8), which elso includes Business On Call (BOC), CILC, end Commercial /Industrial Demand Reduction (CDR).

Col. (10) represents a HYPOTHETICAL "Net Firm Demend" as if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col.(2) - Col.(6) - Col.(8).

Schedule 3.1
History and Forecast of Summer Peak Demand (MW)
(Projected)

(1) August of Year	(2) Total	(3) Wholesela	(4) Retail	(5) Interruptible	(6) Res. Load Manegement	(7) Residential Conservation	(8) C/I Load Management	(9) C/I Conservation	(10) Net Firm Demand
2011	21,679	383	21,295	0	1,005	79	858	39	19,697
2012	21,853	385	21,468	0	1,017	154	676	93	19,712
2013	22,155	343	21,812	0	1,023	244	698	154	19,837
2014	23,452	1,129	22,322	0	1,041	343	934	216	20,917
2015	24,172	1,136	23,037	0	1,044	442	952	272	21,462
2016	24,605	1,143	23,463	0	1,047	536	971	316	21,734
2017	25,025	1,150	23,875	0	1,050	625	989	353	22,006
2016	25,266	1,157	24,109	0	1,053	711	1,007	378	22,117
2019	25,690	1,165	24,526	0	1,056	792	1,026	397	22,419
2020	26,193	1,172	25,022	0	1,060	837	1,042	412	22,823

Projected Values (2011 - 2020):

Col. (2) - Col. (4) represent FPL's forecasted peak w/o incrementel conservation, cumulative load management, or Incremental load management.

Col. (5) - Col. (9) represent cumulative load management, and incremental conservation and load management. All values ere projected August values. The 2011 values are based on IRP projections after the 2010 Summer peak and FPL's new DSM Goals for 2011. The projections for 2012 through 2020 ere besed on FPL's DSM Goels.

Col. (8) represents FPL's Business On Call, CDR, CILC, and Curtailable programs/rates.

Col. (10) represents a "Net Firm Demand" which accounts for all of the incremental conservation end assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.2
History and Forecast of Winter Peak Demand:Base Case
(Historical)

(1) Year	(2) Total	(3) Firm Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management	(7) Residential Conservation	(8) C/I Load Management	(9) C/I Conservation	(10) Net Firm Demand

OCT	19,116	9,020	19,582	9,728	19,740	9,872
NOV	17,052	8,145	17,922	8,099	18,082	8,255
DEC	21,153	8,619	17,787	8,202	17,946	8,383
TOTALS		114,373		111,175		112,517

Cols. (4) - (7) do not include the impacts of cumulative load management, incremental conservation, and incremental load management and are consistent with values shown in Col. (19) of Schedule 2.3 and Col. (2) of Schedule 3.3.

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990s and has since utilized this approach, in whole or in part as analysis needs warranted, to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of new power plants, the primary subjects of this document, are determined as part of the IRP process work.

This section describes FPL's basic IRP process. Some of the key assumptions, in addition to a new load forecast, that were used in developing the resource plan presented in this Site Plan are also discussed.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental steps to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Evaluate the competing options and resource plans in regard to system economics and non-economic factors; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

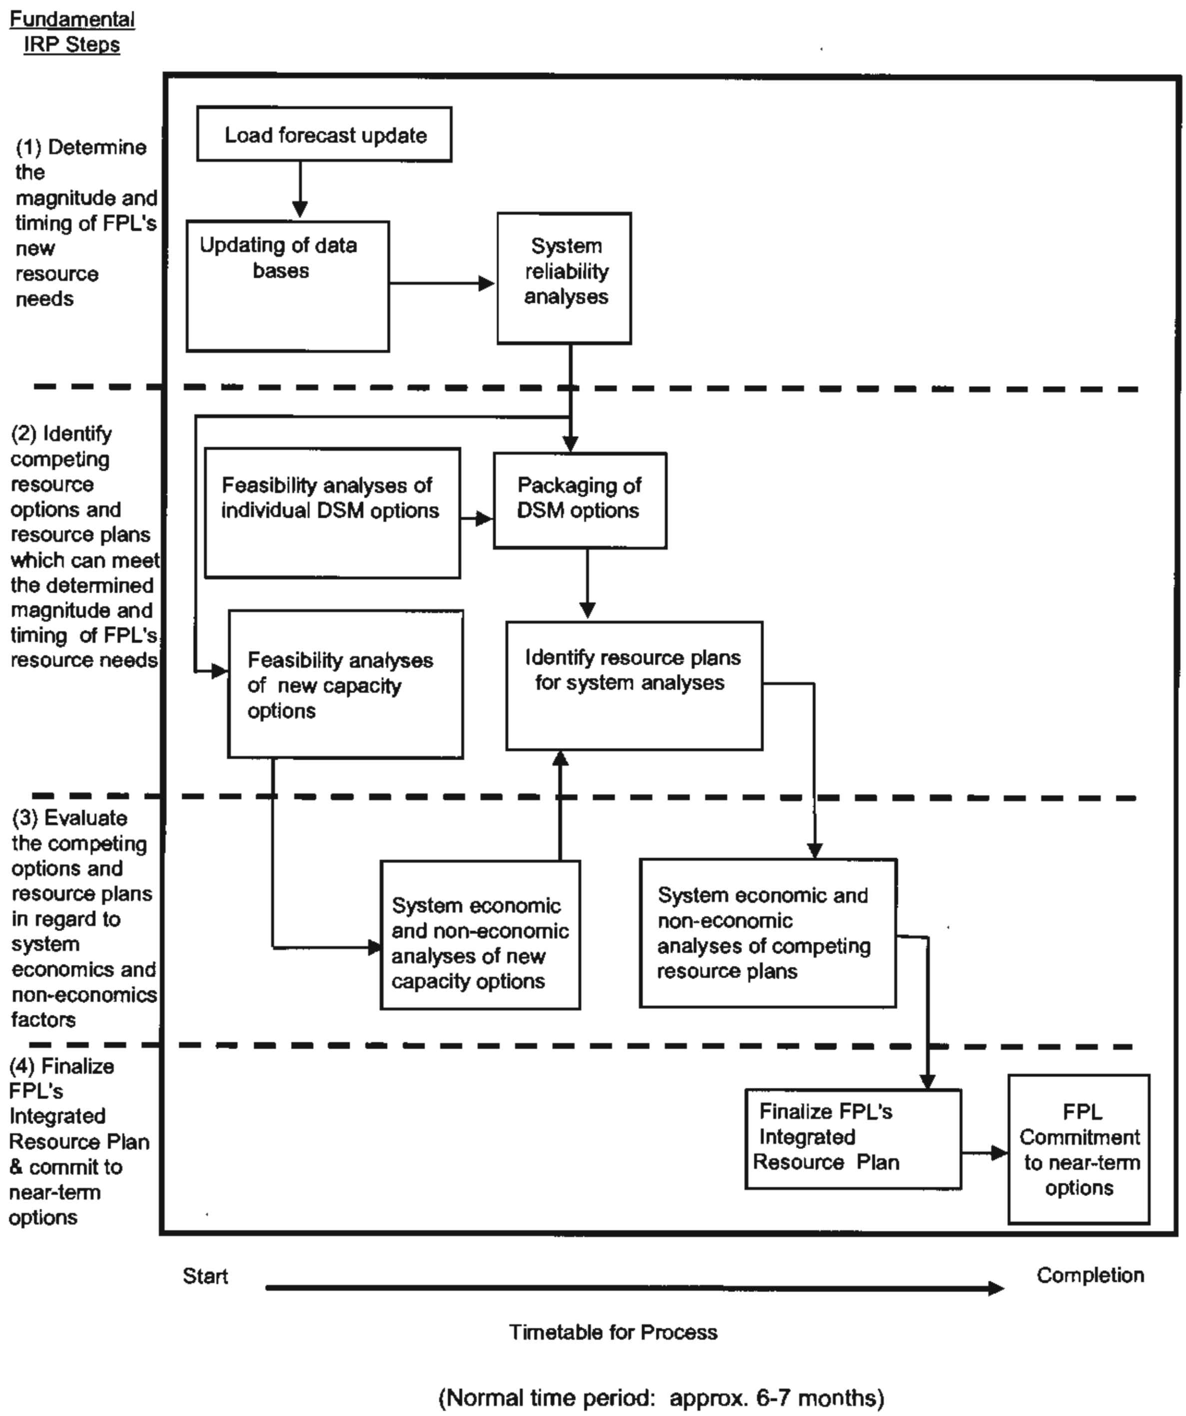

Figure III.A.1: Overview of FPL's IRP Process

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of the four resource planning steps, determining the magnitude and timing of FPL's resource needs, is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed to maintain system reliability. Also determined in this step is when the MWs are needed to meet FPL's reliability criteria. This step is often referred to as a reliability assessment, or resource adequacy, analysis for the utility system.

Step 1 typically starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information that is used in many of the fundamental steps in resource planning. Examples of this new information include, but are not limited to: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) firm capacity power purchases, and (3) DSM implementation.

The first of these assumptions is based on new generating capacity additions that have been approved by the Florida Public Service Commission (FPSC) through Determination of Need proceedings that evaluated both the need for, and the cost-effectiveness of, each of the new capacity additions. These generating capacity additions have also received the necessary Site Certification approvals from either the Secretary of the Florida Department of Environmental Protection (FDEP) or the Governor and Cabinet (acting as the Siting Board). (There is also work in progress to obtain the necessary federal and state licenses, permits, and approvals for construction and operation of two new nuclear units whose earliest practical deployment dates are outside of the 2011 – 2020 reporting period of this Site Plan.)

Several new generating unit additions will occur in the 2011 – 2020 reporting time frame of this document. These generating unit additions include:

- The completion of a third gas-fired CC unit at FPL's West County Energy Center (WCEC) site which is scheduled to come in-service in June 2011. This new unit, WCEC Unit 3, will add approximately 1,219 MW (Summer) of generation capacity.

FPSC approval for this unit was obtained in September 2008 and site certification was granted in November 2008.

- Two existing generating plant sites, each featuring two older fossil fuel-fired steam generating units, are in the process of being modernized by removing the existing generating units and replacing them with one new, highly efficient CC unit. The new CC plant at FPL's Cape Canaveral site is projected to be placed in-service in 2013. This new CC unit is projected to have a peak output of 1,210 MW and will be called the Cape Canaveral Next Generation Clean Energy Center. The new plant at FPL's Riviera site is projected to be placed in-service in 2014 and it is expected to have a peak output of 1,212 MW. This new plant will be called the Riviera Beach Next Generation Clean Energy Center. These modernizations were approved by the FPSC in September 2008. The site certification application for Cape Canaveral was granted in October 2009. The site certification application for Riviera Beach was granted in November 2009.
- In addition, FPL will be adding approximately 450 MW of generating capacity at its existing nuclear power plants at the Turkey Point and St. Lucie sites. This added capacity is scheduled to come in-service in the 2011 – 2013 time period. These capacity "uprates" were approved by the FPSC in January 2008. The Final Order for the Site Certification was issued in September 2008 for the St. Lucie uprates and in October 2008 for the Turkey Point uprates.

These new generating units and generating capacity additions were selected for a variety of reasons including cost-effectiveness, significant system fuel savings, fuel diversity, and significant system emission reductions, including greenhouse gas emission reductions.

The second of these assumptions involves firm capacity power purchases. FPL's current projection of firm capacity purchases is generally similar to the projection shown in FPL's 2010 Site Plan. However, FPL's current projection does include an additional 90 MW from the Palm Beach Solid Waste Authority (SWA). FPL and SWA are currently seeking FPSC approval for this capacity addition. In total, the projected firm capacity purchases are from a combination of utility and independent power producers. Details, including the annual total capacity values for these purchases, are presented in Chapter I in Tables I.B.1 and I.B.2. These purchased capacity amounts were incorporated in FPL's resource planning work.

The third of these assumptions involves a projection of the amount of additional demand side management (DSM) that is anticipated to be implemented annually over the ten-year period. Since 1994, FPL's resource planning work has assumed that, at a minimum, the DSM MW called for in FPL's approved DSM Goals will be achieved as planned. The resource plan presented in FPL's 2011 Site Plan fully accounts for the new DSM goals.

These key assumptions, plus the other updated information described above, are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's future resource needs. This determination is accomplished by system reliability analyses which for FPL are currently based on dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the reliability of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss-of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program used by FPL.

The result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. Information regarding the timing and magnitude of these resource needs is then used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, preliminary economic screening analyses of new capacity options are often conducted to determine which new capacity options appear to be the most competitive on FPL's system. This preliminary analysis work can also help identify capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs. Similarly, preliminary economic screening analyses of new DSM options and/or continued growth in existing DSM options are typically conducted.

FPL typically utilizes the P-MArea production cost model and a Fixed Cost Spreadsheet, and/or the Strategist model, as well as spreadsheet analyses, to perform the preliminary economic screening of generation resource options. For the preliminary economic screening analyses of DSM resource options, FPL typically uses its DSM cost-effectiveness model which is an FPL spreadsheet model utilizing the FPSC's approved methodology for performing preliminary cost-effectiveness screening of individual DSM measures and programs. FPL also utilizes its non-linear programming model for analyzing the potential for lowering system peak loads through additional load management capacity. Then FPL typically utilizes its linear programming model to develop DSM portfolios that are subsequently used in developing resource plans for final system analyses of DSM-based resource plans.

The individual new resource options emerging from these preliminary economic screening analyses are then typically "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's projected new resource needs are met. The creation of these competing resource plans is typically carried out using spreadsheet and/or dynamic programming techniques.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs are identified.

Step 3: Evaluate the Competing Options and Resource Plans in Regard to System Economics and Non-Economic Factors:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for evaluating these resource options and resource plans in final, or system, economic analyses that attempt to account for all of the impacts to the FPL system from the competing resource options/resource plans. (These system impacts are typically not accounted for in preliminary economic screening analyses.) In FPL's 2010 and early 2011 resource planning work, once the resource plans were developed, FPL utilized the P-MArea production cost model and a Fixed Cost Spreadsheet, and/or the Strategist model, to perform the system economic analyses.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the objective generally being to minimize FPL's projected leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). In cases in which the DSM contribution was assumed as a given and the only competing options were new generating units and/or purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans in such cases were evaluated on a cumulative present value revenue requirement (CPVRR) basis.

Other factors are also included in FPL's evaluation of resource options and resource plans. While these factors may have an economic component or impact, they are often discussed in quantitative, but non-economic terms, such as percentages, tons, etc. rather than in terms of dollars. These factors are often referred to by FPL as "system concerns" that include (but are not necessarily limited to) maintaining/enhancing fuel diversity in the FPL system, system emission levels, and maintaining a regional balance between load and generating capacity, particularly in the Southeastern Florida counties of Miami-Dade and Broward. In conducting the evaluations needed to determine which resource options and resource plans are best for FPL's system, both the economic and non-economic evaluations are conducted with an eye to whether the system concern is positively or negatively impacted by a given resource option or resource plan.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps are typically used to develop the current resource plan. This plan is presented in the following section.

III.B Projected Incremental Resource Additions/Changes

FPL's projected incremental generation capacity additions/changes for 2011 through 2020 are depicted in Table III.B.1. These capacity additions/changes result from a variety of actions that primarily consist of: (i) changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls), (ii) the construction of an approved third new generating unit at the West County Energy Center (WCEC), (iii) increases in generating capacity at FPL's four existing nuclear units, (iv) the temporary return of certain generating units from Inactive Reserve status to active service, then returning these units to Inactive Reserve status, (v) changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, (vi) the projected modernizations of FPL's existing Cape Canaveral and Riviera sites by the removal of the steam generating units that were previously on the sites and the addition of one new, very fuel-efficient CC generating unit at each site, and (vii) the projected addition of new, very fuel-efficient new CC generating capacity at sites yet to be determined.[3]

[3] These new CC capacity additions may take the form of new CC units at Greenfield sites, Brownfield sites, and/or through modernizations at existing sites. These decisions have not yet been made at the time the 2011 Site Plan was being developed. For reference purposes, these additions are referred to in the 2011 Site Plan as "Greenfield CC units".

Although the DSM additions that are consistent with the DSM goals imposed by the FPSC through 2020 are not explicitly presented in this table, these DSM additions have been fully accounted for in all of FPL's resource planning work reflected in this document. In addition, the projected MW reductions from these DSM additions are reflected in the projected reserve margin values shown in the table below and in Schedules 7.1 and 7.2 presented later in this chapter.

Table III.B.1: Projected Capacity Changes for FPL

Projected Capacity Changes for FPL (1)			
		Net Capacity Changes (MW)	
Year	Projected Capacity Changes	Winter (3)	Summer (4)
2011	Inactive Reserve of Existing Units - offline (8)	(775)	(1,922)
	Riviera Plant - removed for modernization	---	(565)
	Scherer Plant - Upgrade	---	26
	St. Lucie Unit 2 Uprate - Outage (7)	---	17
	St. Lucie Unit 2 - Interim Increase (7)	(726)	---
	West County Unit 3 (6)	---	1,219
2012	Changes to Existing Purchases (5)	---	(100)
	St. Lucie Unit 1 Uprates - Completed	—	122
	Turkey Point Unit 3 Uprates - Completed	—	109
	Inactive Reserve of Existing Units - offline (8)	(394)	---
	Inactive Reserve Units (PE Units 3 & 4) - active status	765	761
	Manatee 2 ESP - Outage (8)	(822)	---
	Riviera Plant - removed for modernization	(571)	---
	Scherer Plant - upgrede	26	---
	St. Lucie Unit 1 Uprate - Outage (7)	(853)	---
	St. Lucie Unit 2 - Interim Increase (7)	17	---
	St. Lucie Unit 2 Uprate - Outage (7)	---	(731)
	Turkey Point Unit 3 Uprate - Outage (7)	(717)	—
	West County Unit 3 (6)	1,335	---
2013	Cape Canaveral Next Generation Clean Energy Center (6)	—	1,210
	St. Lucie Unit 1 Uprates - Completed	122	---
	St. Lucie Unit 2 Uprates - Completed	93	93
	Turkey Point Unit 3 Uprates - Completed	109	---
	Turkey Point Unit 4 Uprates - Completed	—	109
	Inactive Reserve Unit (PE Units 3 & 4) - inactive status (9)	(765)	(761)
	Manatee Unit 1 ESP - Outage (8)	(822)	---
	Martin Unit 1 ESP - Outage (8)	--	(826)
2014	Cape Canaveral Next Generation Clean Energy Center (6)	1,355	---
	Turkey Point Unit 4 Uprates - Completed	109	---
	Martin Unit 1 ESP - Outage (8)	(832)	---
	Martin Unit 2 ESP - Outage (8)	—	(826)
	Riviera Beach Next Generation Clean Energy Center (6)	—	1,212
2015	Change to Existing Qualifying Facilities (5)	—	90
	Riviera Beach Next Generation Clean Energy Center (6)	1,344	---
2016	Changes to Existing Purchases (5)	(841)	(1,306)
	Change to Existing Qualifying Facilities (5)	—	---
	Greenfield 3x1 Combined Cycle (6)	—	1,191
2017	Changes to Existing Purchases (5)	(383)	---
	Greenfield 3x1 Combined Cycle (6)	1,351	---
2018	—	---	---
2019	—	---	---
2020	Greenfield 3x1 Combined Cycle (6)	---	1,191

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) The Summer and Winter reserve margins reflect an additional 350 MW in Summer and 550 MW in Winter of unspecified average capacity scheduled to be out during those peak periods. See Chapter III for more details.
(3) Winter values are forecasted values for January of the year shown.
(4) Summer values ara forecasted values for August of the yeer shown.
(5) These are firm capacity and energy contracts with QF, utilities, and other entities. See Table I.B.1 and Table I.B.2 for more details.
(6) All new unit additions are scheduled to be in-service in June of the year shown. All additions essumed to stert in June ere included in the Summer reserve margin calculation starting in that year and in the Winter reserve margin calculation starting with the naxt year.
(7) Outages for uprete work.
(8) Outages for ESP work. (Assumes EPA final Toxics Rula requires ESPs, thus necessitating outages.)
(9) A number of existing FPL power plants heve been removed from service and placed on Inactive Reserve status. See Chapter III for e discussion of the units on Inactive Reserves.

III.C Discussion of the Projected Resource Plan and Issues Impacting FPL's Resource Planning Work

As indicated in the Executive Summary, FPL's resource planning efforts in 2010 and early 2011 were influenced by a number of factors. Furthermore, these factors are expected to continue to influence FPL's resource planning work for the foreseeable future. There are 7 such factors that are of primary importance:

1) Growing difficulty in scheduling fossil-fueled power plant maintenance;
2) High projected costs of returning generating units on Inactive Reserve status to active service;
3) Securing additional natural gas (and doing so in a manner that enhances the reliability of the natural gas supply system);
4) Maintaining/enhancing fuel diversity in the FPL system;
5) Maintaining a balance between load and generating capacity in Southeastern Florida, particularly in Miami-Dade and Broward counties;
6) Growing dependence upon DSM resources to maintain FPL system reliability; and,
7) Possible establishment of "Clean Energy Standards" or another mechanism to promote large scale utilization of renewable energy.

These 7 factors, and their various impacts on FPL's resource planning efforts including the current resource plan that is presented in this Site Plan, are briefly discussed below.

1. Growing Difficulty in Scheduling Fossil-Fueled Power Plant Maintenance:

FPL's fleet of fossil generation units is increasingly made up of CC units. These units have the desirable attributes of being very fuel-efficient and operating with very low air emissions. However, the key components of each CC unit are combustion turbines (CT). The maintenance schedule for the CT components is directly tied to the CT's operating hours. When operating hour thresholds are reached, scheduled maintenance of the CTs must take place. This fact reduces flexibility in scheduling planned maintenance of CC units, and, in turn, reduces flexibility in scheduling planned maintenance of other fossil-fueled generating units on FPL's system.

FPL has historically attempted to avoid scheduling planned maintenance of its generating units during its peak load months of January and August. However, as the number of CC units on its system has increased (and will continue to increase with the addition of WCEC 3, the modernizations, etc.), this scheduling of planned maintenance outside of the peak months has become more difficult to do. Compounding this issue is the fact that the Winter peak can occur in months other than January such as December or February, and the Summer peak can occur in months other than August such as June or July. FPL already schedules planned maintenance during these other months.

Consequently, FPL will now begin scheduling planned maintenance during the months of January and August. For reserve margin projection purposes, FPL is now projecting that, on average, 550 MW will be out of service for planned maintenance during its Winter peak months and 350 MW will be out of service for planned maintenance during its Summer peak months. These projections are based on averages of currently planned maintenance in Winter peak months other than January, and on averages of currently planned maintenance in Summer peak months other than August.

This projection of scheduled planned maintenance during peak months is now reflected in Schedules 7.1 through 7.4 which present, respectively, the projected Summer and Winter reserve margins. (In practice, the actual number of MW that will be out of service on any day in January and/or August will likely vary from these average amounts.) One effect of this change is that it increases FPL's projected resource needs in future years.

2. Projected High Costs of Returning Generating Units on Inactive Reserve Status to Active Service:

In FPL's 2010 Site Plan, FPL's then-current resource plan (reflecting FPL's 2009 and early 2010 resource planning work) assumed that the generating units that were being placed on Inactive Reserve status would begin to be returned to active service as needed to maintain system reliability. No economic analyses had been done at that time to compare this option to other alternatives. FPL's recent analyses of these generating units, particularly regarding the projected high costs of returning them to active service in comparison with the net system costs of new generation options, indicate that the addition of new generation will be less costly.

In comparison with new CC capacity, FPL's ongoing analyses currently show that it is projected to be more cost-effective for FPL's customers to add new CC capacity rather than to return the Inactive Reserve units to active service. As a result, FPL currently projects the following in regard to the units currently on Inactive Reserve status:

- Sanford 3 and Cutler 5 & 6 are projected to be retired by 2012. FPL will be examining other potential uses for these sites, including their potential use as sites for new renewable energy facilities.
- Turkey Point 2 operation has been changed from a unit that provides electricity to the grid to a synchronous condenser that provides voltage support for the transmission system in Southeastern Florida. Turkey Point 2 is currently projected to continue serving in this role for the foreseeable future.
- Two of the four steam units at FPL's Port Everglades site, Port Everglades units 3 & 4, are currently scheduled to be returned to active service in 2012, then to return to Inactive Reserve status until the modernized units at Cape Canaveral and Riviera are in normal operation (i.e., until mid-2014). A decision on the future role of these two units will be made at that time or at a later date.
- The remaining units on Inactive Reserve, Port Everglades 1 & 2, will remain on Inactive Reserve status for the immediate future. A decision on their future roles will be made at a later date.

FPL's current projections indicate that the Inactive Reserve units are not the economic choice with which to meet FPL's future resource needs. FPL currently projects that it will have resource needs beginning in 2016 and increasing each year through 2020, the last year of the reporting period of this document.

For planning purposes, FPL's 2011 Site Plan shows the addition of one new "Greenfield" CC unit in 2016 and another new Greenfield CC unit in 2020. These new CC units are currently projected to be the same type of unit that is being added in the modernizations of Cape Canaveral and Riviera. These projected in-service dates are subject to change as a result of FPL's on-going resource planning work.

As mentioned previously in a footnote, FPL has not yet made a decision regarding the site for new CC capacity additions. Therefore, new CC capacity could be added at a Greenfield site, a Brownfield site, and/or at an existing site as part of a modernization similar to those currently taking place at FPL's Cape Canaveral and Riviera sites.

In regard to potential modernization of existing sites, there are a number of factors that must be analyzed including: fuel delivery costs/issues, transmission impacts (especially in the Southeastern region of Florida as will be discussed later), system reliability issues due to the removal of existing units from active service prior to construction of new capacity at the site, overall system economics, etc. FPL's analyses to-date have identified Port Everglades as a potential candidate for modernization. This site, plus other Greenfield and Brownfield sites, is being evaluated in FPL's on-going analyses. These potential sites are discussed in detail in Chapter IV.

3. Securing Additional Natural Gas:

The recent trend of increasing reliance upon natural gas to produce electricity for FPL's customers is projected to continue with the addition of WCEC 3, the Cape Canaveral modernization, and the Riviera modernization, plus the projection of new CC capacity starting in 2016. Therefore, FPL will need to secure more natural gas supply and more gas transportation capacity. The issue is how to secure these additional natural gas resources in a manner that is economical for FPL's customers and which maintains and/or enhances the reliability of natural gas supply and deliverability to FPL's generating units.

FPL has historically purchased the gas transportation capacity required for new natural gas supply from two existing natural gas pipeline companies. As more natural gas is delivered through two pipelines entering Florida, the impact of a supply disruption on either pipeline becomes more problematic. Therefore, FPL sought approval in 2009 from the FPSC for the construction of a new, third natural gas pipeline into Florida capable of serving future gas-fired generation needs for FPL and others in the state. Such a third pipeline was projected to have benefits for FPL and its customers by increasing the diversity of FPL's fuel supply sources, increasing the physical reliability of the pipeline delivery system, and enhancing competition among pipelines. However, the application for an FPL-owned pipeline was denied by the FPSC in 2009. FPL is continuing to evaluate how additional significant amounts of natural gas can best be delivered to its system in the future and FPL will be addressing this issue with the FPSC in 2011.

4. **Maintaining/Enhancing System Fuel Diversity;**

FPL is currently dependent upon using natural gas to generate more than half of the electricity it delivers to its customers. In the future, the percentage of FPL's electricity that is generated by natural gas is projected to steadily increase. Therefore, FPL is continually seeking opportunities to maintain and enhance the fuel diversity of its system.

In 2007, FPL sought approval from the FPSC to add two new advanced technology coal units to its system. These two new units would have been placed in-service in 2013 and 2014. However, in part due to concerns over potential greenhouse gas emission legislation/regulation, FPL was unable to obtain approval for these units. Consequently, FPL does not believe that new advanced technology coal units are viable fuel diversity enhancement options in Florida for the foreseeable future.

Therefore, FPL has turned its attention to nuclear energy and renewable energy to enhance its fuel diversity, and to using natural gas more efficiently. In regard to nuclear energy, FPL obtained approval to increase capacity at each of its four existing nuclear units. In total, these capacity "uprates" will add approximately 450 MW of nuclear capacity and energy for FPL's customers beginning in the 2011 - 2013 time period. In 2008, the FPSC approved the need for these uprates and authorized FPL to recover uprates-related expenditures. The schedule for this additional nuclear capacity has changed slightly from that projected in FPL's 2010 Site Plan. An "interim" capacity increase of approximately 17 MW (FPL's share) from St. Lucie 2 is now projected to become available by April 2011. No such "interim" capacity increase was projected in the 2010 Site Plan. Another projected change involves the schedule for St. Lucie 1. The completion of the uprates work is now projected to occur several months later than originally projected, primarily due to delays in federal licensing for this project. Smaller delays in the completion of the uprate projects at St. Lucie 2 and Turkey Point 3 are also now projected.

FPL is continuing its work to obtain all of the licenses, permits, and approvals that would be necessary to construct and operate two new nuclear units at its Turkey Point site in the future. These licenses, permits, and approvals will provide FPL with the option to construct these nuclear units at Turkey Point for a time expected to be up to 20 years from the time the licenses and permits are granted, and then to operate the units. A decision regarding construction of these new units will be made once the licenses and permits are granted. (Based on the current estimated time for construction, the earliest practical deployment dates for the two new units would be beyond the 10-year reporting period for this Site Plan. Therefore, these units are not shown in this document.)

FPL also has been involved in activities to investigate adding or maintaining renewable resources as a part of its generation supply. One of these activities is a variety of discussions with the owners of existing facilities aimed at maintaining or extending current agreements that are scheduled to end during the ten-year reporting period of this document. Also FPL sought and received approval from the FPSC in 2008 to add 110 MW through three new FPL-owned solar facilities, one solar thermal facility and two photovoltaic (PV) facilities. One 25 MW PV facility began commercial operation in 2009. The remaining two solar facilities, a 10 MW PV facility and a 75 MW solar thermal steam generating facility, began commercial operation in 2010. The addition of these renewable energy facilities was made possible due to enabling legislation from the Florida Legislature in 2008. FPL remains strongly supportive of Federal and/or State legislation that enables electric utilities to add renewable energy resources and authorize the utilities to recover costs for these resources.

In regard to using natural gas more efficiently, FPL received approvals in 2008 from the FPSC to build a third highly efficient CC unit at its West County Energy Center site (WCEC Unit 3) and to modernize the existing Cape Canaveral and Riviera plant sites with new, highly efficient CC units that replace the former steam units. WCEC Unit 3 is currently projected to go in-service in 2011. The modernizations of Cape Canaveral and Riviera are currently projected to go in-service in 2013 and 2014, respectively.

In the future, FPL will continue to identify and evaluate alternatives that may maintain or enhance system fuel diversity. FPL also plans to maintain the ability to utilize fuel oil at those existing units that have that capability, although cost factors currently limit the expected use of this fuel. Furthermore, as previously discussed, FPL continues to evaluate the potential for greater diversity in the delivery of natural gas through a new, third natural gas pipeline. A third pipeline would result in a more reliable, and more economic, natural gas supply for FPL's customers.

5. Maintaining a Balance Between Load and Generation in Southeastern Florida:

In recent years, an imbalance was projected to develop between regionally installed generation and regional peak load in Southeastern Florida. With such an imbalance, a significant amount of energy required in the Southeastern Florida region during peak periods would need to be provided either by operating less efficient generating units located in Southeastern Florida out of economic dispatch, or by importing the energy through the transmission system from plants located outside the region. FPL's prior planning work concluded that either additional installed generating capacity in this region, or additional installed transmission capacity capable of delivering electricity from outside the region, would be required to address this imbalance.

Partly because of the lower transmission-related costs resulting from their location, four recent capacity addition decisions (Turkey Point Unit 5 and WCEC Units 1, 2, & 3) were evaluated as the most cost-effective options to meet FPL's capacity needs in the near-term. Adding these units contributes to reducing the imbalance between generation and load in Southeastern Florida.

In addition, FPL will be adding increased capacity at FPL's existing two nuclear units at Turkey Point in 2012 and 2013 and will increase the generating capacity at its Riviera site through a modernization of that site in 2014. These generating unit additions in Southeastern Florida are expected to address the imbalance for most, if not all, of the 2011 - 2020 reporting period addressed in this document.

However, because of the combination of a number of factors including: (i) the projected retirement of the Cutler 5 & 6 units, (ii) placing the Port Everglades steam units (Units 1 – 4) on Inactive Reserve status for most of this reporting period, (iii) dedicating Turkey Point 2 to a transmission support role, plus (iv) projected growth in electrical demand in the region, FPL still projects that an imbalance between generation and load in the region will eventually occur. The recent WCEC unit additions, and the modernization of the Rivera site, have had the effect of effectively "shrinking" the region of concern regarding imbalance. The former area of concern included Miami-Dade County, Broward County, and parts of Palm Beach County. After these capacity additions in Palm Beach County, the region of concern regarding a load-generation imbalance for the foreseeable future now consists of Miami-Dade and Broward counties, which is south of the former area of concern.

The Southeastern Florida imbalance issue will remain a consideration in FPL's on-going resource planning work, particularly as FPL's planning analyses in future years begin to increasingly focus on the 2020-on time frame.

6. Growing Dependence Upon DSM Resources to Maintain System Reliability:

In late 2009, the FPSC imposed significantly higher DSM Goals than had been deemed appropriate in previous DSM Goals dockets. One result of the higher amounts of DSM is that it will result in higher electric rates for all of FPL's customers.

Another result is that FPL is projected to become increasingly dependent upon DSM, instead of generation resources, to maintain system reliability. In order to demonstrate this point, FPL has added two new schedules, Schedule 7.3 and 7.4, to its 2011 Site Plan. These new schedules are presented in the back portion of this chapter. Both of the new schedules use Schedule 7.1, which presents FPL's projected Summer reserve margins, as a starting point.

In Schedule 7.3, Column (14), FPL projects what a "generation-only" reserve margin would be for each year in the 10-year reporting period by making two changes in Schedule 7.1. First, the projected DSM values in Column (8) have been zeroed out to remove the projected contribution from DSM. Second, the projected additions of one Greenfield CC unit in both 2016 and 2020 have been removed. These two changes result in a projection of reserve margins that are based solely on generation resources that currently exist or which have been approved by the FPSC.

The result is a projected generation-only reserve margin in the range of approximately 11% to 12% through 2015, but which would decrease significantly thereafter. It decreases to 4.5% in 2016 and becomes negative by 2020.

In Schedule 7.4, the projected additions of the 2016 and 2020 Greenfield CC units have been added back in as indicated by the values in Column (1). The projected generation-only reserve margin for the year 2016 increases to 9.3%. Although substantially higher than the 4.5% value for 2016 projected in Schedule 7.3, the 9.3% value is also considerably lower than the 11% to 12% range for the years 2011 through 2015. In the years after 2016, the projected generation-only reserve margin steadily decreases to less than 5% by 2019. Even with the projected addition of another new CC unit in 2020, this generation-only reserve margin does increase again, but only slightly above 7%.

Therefore, FPL's projected system reserves, already dependent to a significant degree upon DSM resources, are becoming increasingly more dependent upon DSM. Stated another way, the FPL system's ability to continue to provide reliable electricity service to FPL's customers is becoming increasingly dependent upon DSM. FPL currently believes that generation-only reserves at these projected low levels may not be adequate, and FPL will continue to evaluate the appropriateness of a minimum generation-only requirement as part of its on-going resource planning work.

7. Possible Establishment of "Clean Energy Standards":

At the time this document is being prepared, neither the United States nor the State of Florida has established a "Clean Energy Standard" which would require that a certain amount of energy be supplied by "clean" energy sources. A similar "Renewable Portfolio Standard" proposal was prepared by the FPSC and sent to the Florida Legislature for their consideration, including an option to change the standard to a Clean Energy Standard, during the 2009 legislative session. However, no such legislation was enacted during either the 2009 or 2010 session. Such legislation, or other legislative initiatives regarding clean energy contributions, may occur in the future. If such legislation is enacted in 2011 or in a later year, FPL will then determine what steps need to be taken to comply with the legislation. Such steps would then be discussed in FPL's Site Plan in the year following the enactment of such legislation.

III.D Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include both conservation initiatives and load management. FPL's DSM efforts through 2010 have resulted in a cumulative Summer peak reduction of approximately 4,371 MW (Summer) at the generator and an estimated cumulative energy saving of approximately 55,462 Gigawatt Hour (GWh) at the generator. After accounting for reserve margin requirements, FPL's DSM efforts through 2010 have eliminated the need to construct more than 13 new 400 MW generating units.

As previously discussed in Chapter I and earlier in this chapter, the FPSC in late 2009 imposed significantly higher DSM Goals for FPL for 2010 – 2019 than were deemed appropriate in prior DSM Goals dockets. The DSM Goals recently imposed by the FPSC have three components: Summer MW reductions, Winter MW reductions, and GWh reductions. Table III.D.1 presents the cumulative Summer MW reduction component of these goals. (The Summer MW component, and to a much lesser degree the Winter MW reduction component, impacts FPL's need for future resources such as those discussed in this document. The GWh reduction component has no impact on FPL's need for future resources.)

Table III.D.1: FPL's Summer MW Reduction Goals for DSM
(at the Generator)

Year	Cumulative Summer MW DSM Goals for FPL (at Generator)
2010	110
2011	253
2012	419
2013	599
2014	783
2015	955
2016	1,111
2017	1,251
2018	1,379
2019	1,498

The next step in regard to FPL's DSM efforts is to obtain FPSC approval for a DSM Plan with which it proposes to meet the DSM Goals. At the time this Site Plan is being prepared, FPL has not received FPSC approval for a DSM Plan. Consequently, FPL does not yet know with certainty what its portfolio of approved DSM programs will be. FPL expects to have an approved DSM Plan later in 2011. (Assuming this is the case, FPL expects to provide a description of its approved DSM programs in its 2012 Site Plan.) Nonetheless, FPL's resource planning work in 2010 and early 2011, reflected in this document, assumed that the FPSC-approved DSM Goals would be met.

FPL has consistently been among the leading utilities nationally in DSM achievement. For example, according to the U.S. Department of Energy's 2009 data (the last year for which the DOE data was available at the time this Site Plan is being developed), FPL ranked # 2 nationally in cumulative DSM demand reduction. And, importantly, FPL has achieved these significant DSM accomplishments while seeking to lessen the DSM-based impact on electric rates for all of its customers.

In regard to DSM, FPL's intent is to meet the FPSC's DSM Goals and to continue its national leadership role in DSM consistent with efforts both to continue to lessen the DSM-based impact on electric rates for all of FPL's customers, and to ensure that FPL's system reliability does not become too dependent upon DSM resources.

III.E Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy to FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV bulk transmission lines that must be certified under the Transmission Line Siting Act.

Table III.E.1: List of Proposed Power Lines

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (KV)	(7) Capacity (MVA)
FPL	St. Johns 1/	Pringle	25	Dec - 16	230	759
FPL	Manatee 2/	BobWhite	30	Dec - 15	230	1190

1/ Final order certifying the corridor was issued on April 21, 2006. This project is to be completed in two phases. Phase I consisted of 4 miles of new 230kV line (Pringle to Pellicer) and was completed in May-2009. Phase II consists of 21 miles of new 230kV line (St. Johns to Pellicer) and is scheduled to be completed by Dec-2016.

2/ Final order certifying the corridor was issued on November 6, 2008. This project consists of 30 miles of new 230kV line (Manatee to Bobwhite) and is scheduled to be completed by Dec-2015

In addition, there will be transmission facilities needed to connect several of FPL's projected generating capacity additions to the system transmission grid. These transmission facilities for the projected generating capacity additions at the West County Energy Center site Unit 3, the capacity increases (uprates) at the existing St. Lucie and Turkey Point nuclear sites, and the Cape Canaveral and Riviera Beach modernizations are described on the following pages.

In regard to the existing generating units that have been placed on Inactive Reserve status, there are no projected impacts to FPL's transmission system from these units.

III.E.1 Transmission Facilities for West County Energy Center (WCEC) Unit 3

The work required to connect West County Energy Center (WCEC) Unit 3 in 2011 to the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Build new Sugar 230 kV Substation on WCEC site.
3. Construct two string busses to connect the collector busses to Sugar 230kV Substation.
4. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
5. At Corbett Substation, relocate Germantown 230 kV line terminal from Corbett to Sugar Sub.
6. At Corbett Substation, relocate Broward/Yamato 230 kV line terminal from Corbett to Sugar Sub.
7. At Corbett Substation, install new Sugar 230 kV line terminal in Bay 2W.
8. At Corbett Substation, install one 5-ohm inductor on the 230 kV side of the 500/230 kV autotransformer.
9. Add relays and other protective equipment.

II. Transmission:

1. Relocate Germantown 230 kV line from Corbett to Sugar.
2. Relocate Broward/Yamato 230 kV line from Corbett to Sugar.
3. Construct one mile 230 kV 1190 MVA line from Sugar to Corbett.

III.E.2 Transmission Facilities for St. Lucie Units 1 & 2 Capacity Uprates

The work required to address the St. Lucie Units 1 & 2 uprates in 2011 for Unit 1 and in 2012 for Unit 2, in regard to the FPL grid is projected to be as follows:

I. Substation:

1. At Midway Substation, replace eleven 230 kV disconnect switches, and remove six wave traps. Also upgrade associated jumpers, bus work and equipment connections.
2. At St. Lucie Switchyard, replace eighteen 230 kV disconnect switches and remove six wave traps.
3. Uprate the Unit 1A and 1B main step-up transformers to 635 MVA. Unit 1B main step-up transformer is to be replaced by the uprated spare main step-up transformer. Existing Unit 1B main step-up transformer is to become the new station spare
4. Uprate the spare main step-up transformer to 635 MVA to replace Unit 2A main step-up transformer.
5. Replace the Unit 2A and Unit 2B main step-up transformer with new one rated at 635 MVA.
6. Add fiber optic relays and other protective equipment.

II. Transmission:

1. Upgrade the three existing St. Lucie-Midway 230 kV lines with spacers between the conductors to achieve a normal (continuous) rating of 2790 Amperes.
2. Replace one existing overhead ground wire on each of the three existing St. Lucie Midway 230kV line with fiber optic overhead ground wire for protective relay communication.

III.E.3 Transmission Facilities for Turkey Point Units 3 & 4 Capacity Uprates

The work required to address the Turkey Point Units 3 & 4 uprates in 2012 in regard to the FPL grid is projected to be as follows:

I. Substation:

1. At Turkey Point Switchyard, install two 5-Ohm series phase inductors combined with external shunt capacitors on the southeast and southwest 230 kV operating busses.
2. At Turkey Point Switchyard, replace twelve 230 kV disconnect switches. Also upgrade associated jumpers, bus work and equipment connections.
3. Uprate the Unit 3 and Unit 4 main step-up transformers to 970 MVA.
4. Replace spare main step-up transformer with 1028 MVA transformer.
5. Add relays and other protective equipment.
6. Replace breaker failure panels at Davis Substation.
7. Replace breaker failure panels at Flagami Substation.

II. Transmission:

1. Upgrade the existing string busses for both Units 3 & 4 between the main step-up transformers and the switchyard with spacers between the conductors.

III.E.4 Transmission Facilities for Cape Canaveral Next Generation Clean Energy Center (Projected Modernization)

The work required to connect the projected Cape Canaveral Next Generation Clean Energy Center in 2013 to the FPL grid is forecasted to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with four breakers to connect the three combustion turbines (CT), and one steam turbine (ST).
2. Construct two string busses to connect the collector busses to Cape Canaveral 230kV Substation.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. At Cape Canaveral Switchyard replace eight 230 kV disconnect switches. Also upgrade associated jumpers, bus work and equipment connections.
5. Expand switchyard relay vault and add relays and other protective equipment.

II. Transmission:

1. Relocate the Cape Canaveral-Grissom 115 kV line.

III.E.5 Transmission Facilities for Riviera Beach Next Generation Clean Energy Center (Projected Modernization)

The work required to connect the projected Riviera Beach Next Generation Clean Energy Center in 2014 to the FPL grid is forecasted to be as follows:

I. Substation:

1. Expand the Riviera 230 kV Switchyard five breakers to accommodate terminals for one combustion turbine (CT), and one steam turbine (ST).
2. Construct a new 138 kV Riviera Switchyard - five bays, 14 breakers with terminals to connect two CT units and seven 138 kV lines.
3. Add four main step-up transformers (3-370 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. Add relays and other protective equipment.
5. At Ranch Substation, add a new 230 kV bay 5 and upgrade bay 4 to 3000 Amperes.
6. Breaker replacements:
   Ranch Substation – Replace one 230 kV breaker
   Broward Substation – Replace one 230 kV breaker

II. Transmission:

1. Break the Indiantown-Riviera 230kV and extend each of the line segments south (approx. 4 miles) to connect to the Ranch 230 kV Substation forming Indiantown-Ranch and a Ranch-Riviera 230 kV circuits.
2. Remove Corbett-Ranch #2 230 kV line at Ranch and:
   a. extend to meet the Cedar-Lauderdale 230 kV line N/S corridor (approx. 10 miles).
3. Break Cedar -Corbett 230 kV (near Ranch Sub in Corbett-Jog section) and:
   a. Extend Cedar side to Riviera, (approx. 15 miles) creating new Cedar-Riviera 230 kV.
   b. Extend Corbett side to meet the Cedar-Lauderdale 230 kV N/S corridor (approx. 10 miles).
4. Break Cedar-Lauderdale 230 kV (near 230 corridor running N/S)
   a. Connect Cedar side to meet 3.b. to create a Cedar to Corbett 230 kV.
   b. Connect Lauderdale side to meet 2.a. to create a Corbett to Lauderdale 230 kV.
5. Upgrade the existing IBM-Yamato 138 kV line to 1200 Amperes.
6. New underground 138 kV tie line between new Riviera 138 kV Switchyard and 560 MVA, 230/138 kV autotransformer in the expanded Riviera 230 kV Substation.
7. Relocate six existing 138 kV lines from existing Riviera 138 kV Switchyard to new Riviera 138 kV Switchyard.

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to effectively utilize renewable energy technologies to serve its customers. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various renewable energy technologies. For purposes of discussing FPL's renewable energy efforts in this document, those efforts will be placed into five categories.

1) **Early Research & Development Efforts:**

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970s in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities in Florida on both a daily and annual basis. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-kilowatt (kW) system was placed into operation in 1984. (The system was removed in 1990 to make room for substation expansion once testing of this PV installation had been completed.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. This FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's early "green pricing" efforts.

2) **Demand Side & Customer Efforts:**

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program ended (due to the fact that it was no longer cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980s, FPL introduced another renewable energy program, FPL's Passive Home Program. This program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for six passive home designs with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the FPSC to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test were deemed to be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

FPL has since continued to analyze and promote the utilization of PV. These efforts have included a PV research, development, and education project, and participation in the State of Florida's PV for Schools program. With resources from the FPL Group Foundation, FPL contributed 30 kw of PV to schools and educational non-profits in its service area during 2010. This initiative also delivers teacher training and curriculum that is tied to the Sunshine Teacher Standards in Florida. Additionally, it provides teacher grants to promote and fund projects in the classrooms. As part of its green pricing research efforts, 2 kw PV arrays were placed in each of 4 schools, and in the Miami Science Museum, for a total of 10 kw of PV in educational facilities. FPL's green pricing efforts also resulted in a 250 kw PV array at Rothenbach Park in Sarasota.

FPL has also been investigating fuel cell technologies through monitoring of industry trends, discussions with manufacturers, and direct field trials. From 2002 through the end of 2005, FPL conducted field trials and demonstration projects of Proton Exchange Membrane (PEM) fuel cells with the objectives of serving customer end-uses while evaluating the technical performance, reliability, economics, and relative readiness of the PEM technology. The demonstration projects were conducted in partnership with customers and included 5 locations. The research projects were useful to FPL in identifying specific issues that can occur in field applications and the current commercial viability of this technology. FPL will continue to monitor the progress of these technologies and conduct additional field evaluations as significant developments in fuel cell technologies occur.

In addition, FPL assists customers who are interested in installing PV equipment at their facilities. Consistent with Florida Administrative Code Rule 25-6.065, Interconnection and Net Metering of Customer-Owned Renewable Generation, FPL works with customers to interconnect these customer-owned PV systems. Through December 2010, approximately 1,074 customer systems (predominantly residential) have been interconnected.

Finally, as part of its DSM Goals decision, the FPSC imposed a requirement for Florida's investor-owned utilities to spend up to a set, not-to-exceed amount of money annually to facilitate demand side solar water heater and photovoltaic applications. FPL's not-to-exceed annual amount of money for these applications is approximately $15.5 million. These expenditures will be made in accordance with the solar water heater and PV aspects of FPL's DSM Plan once FPL receives approval for its Plan.

3) **Supply Side Efforts – Power Purchases:**

FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy, and as-available energy, have been purchased by FPL from these types of facilities. (Please refer to Tables I.B.1, I.B.2, and Table I.C.1 in Chapter I).

Periodically, FPL invites renewables suppliers to provide proposals for renewable power and energy at or below avoided costs in response to FPL's Requests for Proposals (RFPs). FPL issued Renewable RFPs in 2007 and 2008 soliciting proposals to provide firm capacity and energy, and energy only, at or below avoided costs from renewable generators. FPL also promptly responds to inquiries for information from prospective renewable energy suppliers either by e-mail or phone.

With regard to existing contracts that have recently ended, FPL and the Solid Waste Authority of Palm Beach (SWA) recently agreed to extend their contract that expired March 31, 2010 for a 20-year term from April 1, 2012 through April 1, 2032. In addition, a new contract for an additional 90 MW between FPL and SWA has been signed and has been submitted to the FPSC for approval. Also, the firm capacity and energy contract with Broward South that expired August 2009 was not renewed, but Broward South continues as an as-available supplier of renewable energy to FPL.

4) **Supply Side Efforts – FPL Facilities:**

With regard to solar projects, FPL has completed construction of three solar facilities: (i) a 75 MW steam generation solar thermal facility in Martin County (the Martin Next Generation Solar Energy Center); (ii) a 25 MW PV electric generation facility in DeSoto County (the DeSoto Next Generation Solar Energy Center); and (iii) a 10 MW PV electric generation facility in Brevard County at NASA's Kennedy Space Center (the Space Coast Next Generation Solar Energy Center). The DeSoto County project was completed in 2009 and the other two projects were completed in 2010. These three projects were completed in response to the Florida Legislature's House Bill 7135 which was signed into law by then-Governor Crist in June 2008. House Bill 7135 (hereafter referred to as the 2008 Energy Bill), was enacted to enable the development of clean, zero greenhouse gas emitting renewable generation in the State of Florida. Specifically, the 2008 Energy Bill authorized cost recovery for the first 110 MW of eligible renewable projects that had the proper land, zoning, and transmission rights in place. FPL's three solar projects met the specified criteria, and were granted approval for cost recovery in 2008. Each of the three solar projects is discussed below.

a. **The Martin Next Generation Solar Energy Center:**

This facility began commercial operation in 2010 and provides 75 MW of solar thermal capacity in an innovative way that directly displaces fossil fuel usage on the FPL system. This facility consists of solar thermal technology which generates steam that is integrated into the existing steam cycle for the Martin Unit 8 natural gas-fired CC plant. This project is the first "hybrid" solar plant in the world, the second largest solar facility in the world, and the largest solar plant of any kind in the U.S. outside of California.

b. **The DeSoto Next Generation Solar Energy Center:**

This PV facility began commercial operation in 2009 and provides up to 25 MW of non-firm capacity and energy, making it the second largest PV facility in the U.S. The facility utilizes a tracking array that is designed to follow the sun as it traverses across the sky.

c. **The Space Coast Next Generation Solar Energy Center:**
Located at the Kennedy Space Center, this facility is part of an innovative public/private partnership with NASA. This non-tracking PV facility began commercial operation in 2010 and provides up to 10 MW of non-firm capacity and energy.

Each of these facilities is a significant and innovative renewable generating plant in its own right. Collectively, these Next Generation Solar Energy Centers are expected to produce a total of approximately 225,000 megawatt-hours (MWh) of electricity each year, and at peak production provide enough energy to serve the requirements of more than 15,000 homes.

For resource planning purposes, FPL projects that the output from these renewable facilities will be "as available", non-firm energy only. This is due to several factors. First, the Martin solar thermal facility is a "fuel-substitute" facility, not a facility that provides additional capacity and energy. The solar thermal facility displaces the use of fossil fuel to produce steam on the FPL system when the solar thermal facility is operating. Second, in regard to the two PV facilities, the intermittent nature of the solar resource makes it difficult to accurately determine what contribution the PV facilities at these specific locations can consistently make at FPL's late Summer afternoon and early Winter morning peak load hours. Once site-specific operating data has been gathered for an appropriate amount of time, FPL will then re-evaluate the actual output from each PV facility to determine what portion, if any, of its output can be projected as firm capacity at the projected peak hours in FPL's resource planning work.

In addition to these three approved projects, FPL is currently in the process of identifying other potential solar sites in the state in the event that a future Renewable Portfolio Standard (RPS), Clean Energy Portfolio Standard (CPS), or other legislation is enacted by the Florida legislature that enables FPL to construct and recover costs for additional solar generation. FPL is evaluating existing FPL generation sites along with potential Greenfield sites within FPL's service territory. These potential FPL and Greenfield sites are discussed further in Chapter IV.

FPL remains hopeful of developing a wind generation project on South Hutchinson Island in St. Lucie County. This project is known as the St. Lucie Wind Project and it would consist of up to six wind turbine generators capable of generating up to approximately 13.8 MW. In 2007, FPL began the St. Lucie County land use approval process, and soon after applied for the necessary federal and state permitting. However, a decision by the state and federal agencies on the St. Lucie Wind Project's permitting will not be finalized until the local land use approval process is completed. At the time this Site Plan is being developed, the local land use approval process has not been completed. An in-service date for the project is dependent upon a successful outcome to the local approval and permitting process.

5) **Ongoing Research & Development Efforts:**

FPL has developed alliances with several Florida universities to promote development of emerging technologies. For example, an alliance has been established with the newly formed Southeast National Marine Renewable Energy Center (SNMREC) at Florida Atlantic University (FAU), which will focus on the commercialization of ocean current, ocean thermal (i.e., energy conversion as well as cold water air conditioning), and hydrogen technologies. FPL has been taking the lead in assisting FAU with the discussions being held with the U.S. Department of the Interior's Minerals Bureau of Ocean Energy Management Regulation and Enforcement (BOEMRE). BOEMRE is working to establish the permitting process for ocean energy development on the outer continental shelf.

FPL has also developed an alliance with the University of Florida to support its biomass-related studies to determine improved vegetative management techniques for use in minimizing maintenance costs at FPL's current and future solar sites and to perform wind studies within the state. In addition, FPL has partnered with the Florida Institute of Technology on fuel cell technology and with the Florida State Universities Center for Applied Power System in regard to grid integration of ocean energy and other renewables.

FPL has also developed a "Living Lab" to demonstrate FPL's solar energy commitment to employees and visitors at its Juno Beach facility. FPL is evaluating multiple solar technologies and applications for the purpose of developing a renewable business model resulting in the most cost-effective and reliable uses of solar energy for FPL customers. FPL will expand the Living Lab as new solar products come to market.

FPL has also been in discussions with several private companies on multiple emerging technology initiatives including ocean current, ocean thermal, hydrogen, fuel cell technology, biomass, biofuels, and energy storage.

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980s, FPL relied primarily on a combination of fuel oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil-fired generation. In the early 1980s, FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit 4 which began serving FPL's customers in 1991. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP.

The trend since the early 1990s has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective CC generating units and the ready availability of natural gas. This planning document reflects an evolution in that trend in recognition that, although efficient gas-fired generation continues to provide significant benefits to FPL's customers, adding natural gas-fired additions exclusively would, in the long term, create an unbalanced generation portfolio. In 2009, FPL placed into commercial operation two new gas-fired CC units at the West County Energy Center (WCEC) site. A third new CC unit will be added to the WCEC site in 2011. In addition, FPL is currently modernizing its existing Cape Canaveral and Riviera plant sites by removing the steam generating units previously on the sites and replacing them with two highly efficient new CC units, one at each site. These new CC units will provide highly efficient generation that will dramatically improve FPL's overall system generation efficiency.

In addition, FPL is increasing its utilization of nuclear energy through capacity uprates of its four existing nuclear units. These uprates will add a total of approximately 450 MW of nuclear generation capacity in the 2011 – 2013 time period. (FPL is also pursuing plans to obtain licenses, permits, and approvals to construct and operate two new nuclear units at its existing Turkey Point site that, in total, would add approximately 2,200 MW of new nuclear generating capacity. The earliest dates by which those new nuclear units could practically be deployed are outside of the ten-year reporting time frame of this document.)

In regard to utilizing renewable energy, FPL has added 110 MW of solar generating capacity through a 75 MW solar thermal facility at FPL's existing Martin site, a 25 MW PV facility in DeSoto County, and a 10 MW PV facility in Brevard County. The 25 MW PV facility was placed into commercial operation in 2009. The other two solar facilities were placed into commercial operation in 2010.

FPL's future resource planning work will continue to focus on identifying and evaluating alternatives that would most cost-effectively maintain and/or enhance FPL's long-term fuel diversity. These fuel diverse alternatives may include: the purchase of power from renewable energy facilities, additional FPL-owned renewable energy facilities, obtaining access to diversified sources of natural gas such as liquefied natural gas (LNG) and natural gas from the Mid-Continent unconventional reserves, preserving FPL's ability to utilize fuel oil at its existing units, and increased utilization of nuclear energy. (As previously discussed, new advanced technology coal generating units are not currently considered as viable options in Florida in the ten-year reporting period of this document due, in part, to concerns over greenhouse gas emissions legislation/regulation.) The evaluation of the feasibility and cost-effectiveness of these, and other possible alternatives, will be part of on-going resource planning efforts.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2020 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

2. FPL's Fossil Fuel Cost Forecasts

Fossil fuel price forecasts, and the resulting projected price differentials between fuels, are major drivers used in evaluating alternatives for meeting future resource needs. FPL's forecasts are generally consistent with other published contemporary forecasts.

Future oil and natural gas prices, and to a lesser extent, coal and petroleum coke prices, are inherently uncertain due to a significant number of unpredictable and uncontrollable drivers that influence the short-and long-term price of oil, natural gas, coal, and petroleum coke. These drivers include:

a. Current and projected worldwide demand for crude oil and petroleum products;

b. Current and projected worldwide refinery capacity/production;

c. Expected worldwide economic growth, in particular in China, and other Pacific Rim countries;

d. Organization of Petroleum Exporting Countries (OPEC) production, the availability of spare OPEC production capacity and the assumed growth in spare OPEC production capacity;

e. Non-OPEC production and expected growth in non-OPEC production;

f. The geopolitics of the Middle East, West Africa, the Former Soviet Union, Nigeria, Venezuela, etc., as well as, the uncertainty and impact upon worldwide energy consumption related to U. S. and worldwide environmental legislation, politics, etc.;

g. Current and projected North American natural gas demand;

h. Current and projected U.S., Canadian, and Mexican natural gas production;

i. The worldwide supply and demand for LNG; and

j. The growth in solid fuel generation on a U. S. and worldwide basis.

The inherent uncertainty and unpredictability in these factors today and tomorrow clearly underscores the need to develop a set of plausible oil, natural gas, and solid fuel (coal and petroleum coke) price scenarios that will bound a reasonable set of long-term price outcomes. In this light, FPL developed and utilized Low, Medium, and High price forecasts for fossil fuels in some of its 2010 and early 2011 resource planning work, particularly in regard to nuclear cost recovery filing work.

FPL's Medium price forecast methodology is consistent for oil and natural gas. For oil and natural gas commodity prices, FPL's Medium price forecast applies the following methodology:

a. For 2011 through 2013, the methodology used the January 14, 2011 forward curve for New York Harbor 1% sulfur heavy oil, U. S. Gulf Coast 1% sulfur heavy oil, ultra low sulfur diesel fuel oil, and Henry Hub natural gas commodity prices;

b. For the next two years (2014 and 2015), FPL used a 50/50 blend of the January 14, 2011 forward curve and the most current projections at the time from The PIRA Energy Group;

c. For the 2016 through 2025 period, FPL used the annual projections from The PIRA Energy Group, and;

d. For the period beyond 2025, FPL used the real rate of escalation provided in the Energy Information Administration (EIA) *Annual Energy Outlook 2011 Early Release* publication. FPL assumed a 2.5% annual rate of escalation to convert real prices to nominal prices prior to 2025, with no escalation from 2025 forward. In addition to the development of oil and natural gas commodity prices, nominal price forecasts also were prepared for oil and natural gas transportation costs. The addition of commodity and transportation forecasts resulted in delivered price forecasts.

FPL's Medium price forecast methodology is also consistent for coal and petroleum coke prices. Coal and petroleum coke prices were based upon the following approach:

a. The price forecasts for Central Appalachian coal (CAPP), Powder River Basin (PRB), South American coal, and petroleum coke were provided by JD Energy;

b. The marine transportation rates from the loading port for coal and petroleum coke to an import terminal were also provided by JD Energy;

c. The coal price forecast for SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements.

The development of FPL's Low and High price forecasts for oil, natural gas, coal, and petroleum coke prices were based on the historical volatility of the 12-month forward price, one year ahead. FPL developed these forecasts to account for the uncertainty which exists within each commodity as well as across commodities. These forecasts reflect a range of reasonable forecast outcomes.

3. Nuclear Fuel Cost Forecast

This section reviews the various steps needed to fabricate nuclear fuel for delivery to the nuclear power plants, the method used to forecast the price for each step, and other comments regarding FPL's nuclear fuel cost forecast.

a) Steps Required for Nuclear Fuel to be delivered to FPL's Plants

Four separate steps are required before nuclear fuel can be used in a commercial nuclear power reactor. These steps are summarized below.

(1) Mining: Uranium is produced in many countries such as Canada, Australia, Kazakhstan, and the United States. During the first step, uranium is mined from the ground using techniques such as open pit mining, underground mining, in-situ leaching operations, or production as a by-product from other mining operations, such as gold, copper, or phosphate rocks. The product from this first step is the raw uranium delivered as an oxide, U3O8 (sometimes referred to as yellowcake).

(2) Conversion: During the second step, the U3O8 is chemically converted into UF6 which, when heated, changes into a gaseous state. This second step further removes any chemical impurities and serves as preparation for the third step, which requires uranium to be in a gaseous state.

(3) Enrichment: The third step is called enrichment. Natural uranium contains 0.711% of uranium at an atomic mass of 235 (U-235) and 99.289% of uranium at an atomic mass of 238 (U-238). FPL's nuclear reactors use uranium with a higher percentage of up to five percent (5%) of U-235 atoms. Because natural uranium does not contain a sufficient amount of U-235, the third step increases the percentage amount of U-235 from 0.711% to a level specified when designing the reactor core (typically in a range from approximately 3% to as high as 5%). The output of this enrichment process is enriched uranium in the form of UF6.

(4) Fabrication: During the last step, fuel fabrication, the enriched UF6 is changed to a UO2 powder, pressed into pellets, and fed into tubes, which are sealed and bundled together into fuel assemblies. These fuel assemblies are then delivered to the plant site for insertion in a reactor.

Like other utilities, FPL has purchased raw uranium and the other components of the nuclear fuel cycle separately from numerous suppliers from different countries.

b) Price Forecasts for Each Step

(1) Mining: There is some volatility in the current uranium market. Current demand continues to be rather stable and outputs from production facilities have been increasing steadily. The following are the current major contributors that led to some volatility in the prices for uranium:

- Hedge funds are now back in the market, now that the recent financial crisis is resolving itself. This causes more speculative demand, not tied to market fundamentals, and causes the market price to move according to news potentially affecting potential future supply/demand balance, or news regarding current suppliers.
- The large inventory from the U.S. Department of Energy (DOE) is being withheld from the market due to political pressure from suppliers. Some of this uranium finds its way into the market periodically to fund cleanup of certain Department of Energy facilities.
- The U.S. Department of Commerce (DOC) has imposed restrictions on the import of nuclear fuel from France and Russia.
- Although a limited number of new nuclear units is scheduled to start production in the US during the next 5 to 10 years, other countries, more specifically China, has announced a significant increase in construction of new units which has caused short term increase in uranium market price.

Over a 10 year horizon, FPL expects the market to be more consistent with market fundamentals The supply picture is more stable, with laws enacted to resolve the import of Russian-enriched uranium, by allowing some imports of Russian-enriched uranium to about 20-25% of needs for currently operating units, but with no restriction on the first core for new units and no restrictions after 2020. New and current facilities continue to add capacity to meet demands. Actual demand tends to grow over time because of the long lead time to build nuclear units. However, FPL cannot discount the possibility of future periodic sharp increase in prices, but believes such occurrences will likely be temporary in nature.

FPL's nuclear fuel price forecasts are the result of FPL's analysis based on inputs from various nuclear fuel market expert reports and studies.

(2) Conversion: FPL's price forecast considers the construction of new nuclear units. Just like for raw uranium, an increase in demand for conversion services would result from this need. Insufficient planned production is currently forecasted after 2013 to meet the higher demand scenario. As with additional raw uranium production, supply will expand beyond current level once more firm commitments are made including commitments to building new nuclear units.

(3) Enrichment: With no new production capacity, the current tight market supply for economically produced enrichment services will continue until 2013. The current diffusion plants, which use significant amount of electricity, can make up any gaps in supply of enrichment services now that prices for electricity have decreased. In addition, there are a number of new facilities coming on-line through 2013, using more efficient and proven processes such as the use of centrifuges for enrichment of uranium. As with supply for the other steps of the nuclear fuel cycle, expansion of future capacity is feasible within the lead time for constructing new nuclear units and any other projected increase in demand. Meanwhile, world supply and demand will continue to be balanced such that FPL expects adequate supply of enrichment services. The tight supply/demand will most likely causes the price of enrichment services to continue to rise in the future.

(4) Fabrication: Because the nuclear fuel fabrication process is highly regulated by the Nuclear Regulatory Commission (NRC), not all production facilities can qualify as suppliers to nuclear reactors in the U.S. Although world supply and demand is expected to show significant excess capacity for the foreseeable future, the gap is not as wide for U.S. supply and demand. The supply for the U.S. market is expected to be sufficient to meet U.S. demand for the foreseeable future.

c) **Other Comments Regarding FPL's Nuclear Fuel Cost Forecast**

The calculations for the nuclear fuel cost forecasts used in FPL's 2010 and early 2011 resource planning work were performed consistent with the method then used for FPL's Fuel Clause filings, including the assumption of refueling outages every 18 months. The costs for each step to fabricate the nuclear fuels were added to come up with the total costs of the fresh fuel to be loaded at each refueling (acquisition costs). The acquisition cost for each group of fresh fuel assemblies were then amortized over the energy produced by each group of fuel assemblies. FPL also added 1 mill per kilowatt hour net to reflect payment to DOE for spent fuel disposal.

All MW additions/changes occuring later in the year will be picked up for reporting/planning purposes in the following year.
(2) The nuclear uprates will be performed during the extended outages for each unit.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** West County Energy Center Combined Cycle Unit 3

(2) **Capacity**
a. Summer 1,219 MW
b. Winter 1,335 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2009
b. Commercial In-service date: 2011

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low No_x Combustors, SCR
0.0015% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 220 Acres

(9) **Construction Status:** V (Under construction, more than 50% Complete)

(10) **Certification Status:** Permitted

(11) **Status with Federal Agencies:** Permitted

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	2.1%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	96.8%	(Base & Duct Firing Operation)
Resulting Capacity Factor (%):	Approx. 93%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,582 Btu/kWh	(Base Operation)
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	30 years
Total Installed Cost (2011 $/kW):	709
Direct Construction Cost ($/kW):	
AFUDC Amount ($/kW):	71
Escalation ($/kW):	
Fixed O&M ($/kW -Yr.): (2011 $kW-Yr)	11.63
Variable O&M ($/MWH): (2011 $/MWH)	0.480
K Factor:	1.4697

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement, but not firm gas transportation costs.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** St. Lucie 1 Nuclear (Uprate)

(2) **Capacity**
a. Summer 122 MW (Incremental)
b. Winter 122 MW (Incremental)

(3) **Technology Type:** Nucleer

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2012

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel —

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	No change from existing unit
Forced Outage Factor (FOF):	No change from existing unit
Equivalent Availability Factor (EAF):	No change from existing unit
Resulting Capacity Factor (%):	No change from existing unit
Average Net Operating Heat Rate (ANOHR):	No change from existing unit
Base Operation 75F,100%	No change from existing unit

(13) **Projected Unit Financial Data** *

Book Life (Years):	25	years (Matches the current operating license period.)
Total Installed Cost ($/kW): **	TBD	(See Note (1) for explanation.)
Direct Construction Cost:	TBD	(See Note (1) for explanation.)
AFUDC Amount ($/kW):		(See Note (2) for explanation.)
Escalation ($/kW):		(See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.):	There is no additional O&M impact from this project.	
Variable O&M ($/MWH):	There is no additional O&M impact from this project.	
K Factor:		(See Note (2) for explanation.)

NOTE:
(1) The projected capital cost values for the capacity uprates at each of FPL's existing nuclear units is currently being reviewed in on-going analyses as this document is being prepared. The capital cost projections that will result from these analyses are expected to be presented in FPL's May 2011 Nuclear Cost Recovery filing.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

* $/kW values are based on incremental Summer capacity.
** $/incremental kW

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Turkey Point 3 Nuclear (Uprate)

(2) **Capacity**
a. Summer 109 MW (Incremental)
b. Winter 109 MW (Incremental)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2012

(5) **Fuel**
a. Primary Fuel Uranium
b. Alternate Fuel ---

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencies:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	No change from existing unit
Forced Outage Factor (FOF):	No change from existing unit
Equivalent Availability Factor (EAF):	No change from existing unit
Resulting Capacity Factor (%):	No change from existing unit
Average Net Operating Heat Rate (ANOHR):	No change from existing unit
Base Operation 75F,100%	No change from existing unit

(13) **Projected Unit Financial Data** *

Book Life (Years):	21	years (Matches the current operating license period.)
Total Installed Cost ($/kW): **	TBD	(See Note (1) for explanation.)
Direct Construction Cost ($/kW):	TBD	(See Note (1) for explanation.)
AFUDC Amount ($/kW):		(See Note (2) for explanation.)
Escalation ($/kW):		(See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.):	There is no additional O&M impact from this project.	
Variable O&M ($/MWH):	There is no additional O&M impact from this project.	
K Factor:		(See Note (2) for explanation.)

NOTE:
(1) The projected capital cost values for the capacity uprates at each of FPL's existing nuclear units is currently being reviewed in on-going analyses as this document is being prepared. The capital cost projections that will result from these analyses are expected to be presented in FPL's May 2011 Nuclear Cost Recovery filing.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

* $/kW values are based on incremental Summer capacity.
** $/incremental kW

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** St. Lucie 2 Nuclear (Uprate)

(2) **Capacity**
a. Summer — 17 MW (Interim Incremental FPL's ownership share), 110 MW (final incremental FPL's ownership share)
b. Winter — 17 MW (Intarim Incremental FPL's ownership share), 110 MW (final incremental FPL's ownarship share)

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**
a. Field construction start-date: During scheduled refueling outage
b. Commercial In-service date: 2011 (Interim increase), 2012 (final increase)

(5) **Fuel**
a. Primary Fuel — Uranium
b. Altarnata Fuel — ---

(6) **Air Pollution and Control Strategy:** No change from existing unit

(7) **Cooling Method:** No change from existing unit

(8) **Total Site Area:** No change from existing unit

(9) **Construction Status:** T (Regulatory approval received, but not under construction)

(10) **Certification Status:** T (Regulatory approval received, but not under construction)

(11) **Status with Federal Agencias:** T (Regulatory approval received, but not under construction)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	No change from existing unit
Forced Outage Factor (FOF):	No change from existing unit
Equivalent Availability Factor (EAF):	No change from existing unit
Resulting Capacity Factor (%):	No change from existing unit
Average Net Operating Heat Rate (ANOHR):	No change from existing unit
Basa Operation 75F,100%	No change from existing unit

(13) **Projected Unit Financial Data *,****

Book Life (Years):	32	years (Matches the current opereting license period.)
Total Installed Cost ($/kW): **	TBD	(See Note (1) for explanation.)
Direct Construction Cost ($/kW):	TBD	(See Note (1) for explanation.)
AFUDC Amount ($/kW):		(See Note (2) for explanation.)
Escalation ($/kW):		(See Note (3) for explanation.)
Fixed O&M ($/kW -Yr.):	There is no additional O&M impact from this project.	
Variable O&M ($/MWH):	There is no additional O&M impact from this project.	
K Factor:		(See Note (2) for explanation.)

NOTE:
(1) The projected capital cost values for the capacity uprates at each of FPL's existing nuclear units is currently being reviewed in on-going analyses as this document is being prepared. The capital cost projections that will result from these analyses are expected to be presented in FPL's May 2011 Nuclear Cost Recovery filing.
nuclear units.
(2) Not applicable due to early recovery of capital carrying costs.
(3) These costs are included in the Total Installed Cost value.

* $/kW values are based on incremental Summer capacity.
** $/incremental kW

Note:
(1) FPL Existing Units Total values on row (7), columns (2) and (4), match the System Firm Generating Capacity values found on Schedule 1 for Summer and Winter.
(2) Net Energy for Load GWh values on row (12), column (6), matches Schedule 6.1 value for 2010.

Schedule 11.2

Existing NON-FIRM Self-Service Renewable Generation Facilities
Actuals for the Year 2010

(1)	(2)	(3)	(4)	(5)	(6) = 3+4-5
Type of Facility	Installed Capacity DC (MW)	Renewable Projected Annual Output (MWh)	Annual Energy Purchased from FPL (MWh)	Annual Energy Sold to FPL (MWh)	Projected Annual Energy Used by Customers (GWh)
Customer-Owned PV (0 kW to 10 kW)	4.6	5,214.7	53,476.4	146.5	**58.5**
Customer-Owned PV (> 10 kW to 100 kW)	1.6	1,775.4	17,858.8	158.2	**19.5**
Customer-Owned PV (> 100 kW to 2 MW)	2.9	3,708.4	118,662.7	177.6	**118,666.2**
Total:	**9.2**	**10,698.5**	**189,998.0**	**482.2**	**118,744.2**

Notes:

(1) There were approximately 1,074 customer-owned renewable generation facilities interconnected with FPL on December 31, 2010.
(2) The Installed Capacity value is the sum of the nameplate ratings (DC MW) for all of the customer-owned renewable generation facilities connected as of Dec. 31,2010.
(3) The Projected Annual Output value is based on NREL's PV Watts 1 program and the Installed Capacity value in column (2), adjusted for the date when each facility was installed and assuming each facility operated as planned.
(4) The Annual Energy Purchased from FPL is an actual value from FPL's metered data for 2010.
(5) The Annual Energy Sold to FPL is an actual value from FPL's metered data for 2010.
(6) The Projected Annual Energy Used by Customers is a projected value that equals:
(Renewable Projected Annual output + Annual Energy Purchased from FPL) minus the Annual Energy Sold to FPL.

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered or threatened plant and animal species. FPL competes for air, land, and water resources that are necessary to meet the demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among electric utilities for its commitment to the environment. For example, FPL has one of the lowest carbon dioxide (CO_2) emission rates in the nation. The environmental leadership of FPL and its parent company, NextEra Energy, Inc., has been heralded by many outside organizations as demonstrated by a few recent examples. In 2010, NextEra Energy, Inc. (formerly FPL Group) ranked in the top 10 among companies worldwide for innovation and, for a record fourth consecutive year, No. 1 in its industry, according to the 2010 "World's Most Admired Companies" report released by Fortune magazine. In addition to being named the most admired company in its industry, NextEra Energy, Inc. received the No. 1 ranking among its peers in the following specific areas evaluated: innovation, people management, use of corporate assets, social responsibility, quality of management, long-term investment, and quality of products and services. According to *Fortune*, America's Most Admired Companies is "the definitive report card on corporate reputations".

NextEra Energy, Inc.'s commitment to acknowledging the risks of climate change and effectively reducing its greenhouse gas emissions was again recognized when the company was named to the Carbon Disclosure Leadership Index for 2010. The Carbon Disclosure Leadership Index is produced annually by the Carbon Disclosure Project (CDP), a not-for-profit organization that reports on the business risks and opportunities of climate change for investors. CDP represents 534 institutional investors with $64 trillion in assets under management. Compiled by PricewaterhouseCoopers on behalf of CDP, the Carbon Disclosure Leadership Index highlights companies within the S&P 500 Index that excel in the area of climate change awareness and action.

NextEra Energy, Inc. was named to the 2010 Dow Jones Sustainability Index (DJSI) of the leading companies in North America for corporate sustainability. The DJSI North America selects the top 20 percent of companies in sustainability performance from the 600 largest companies in North America. According to Dow Jones, corporate sustainability leaders achieve long-term shareholder value by "gearing their strategies and management to harness the market's potential for sustainability products and services while successfully reducing and avoiding sustainability costs and risks."

FPL was recognized in 2010 by the Southeastern Electric Exchange (SEE) for outstanding performance in constructing the largest solar photovoltaic (PV) power plant at the time in the United States: the 25 MW DeSoto Next Generation Solar Energy Center. SEE gives its Chairman's Award annually to the project it deems "best of the best" among all entrants in its 11 award categories. Capable of powering approximately 3,000 homes with renewable energy, the DeSoto PV facility was completed months ahead of schedule and more than $22 million under budget.

FPL's responsible tree care practices across its 35-county service area have been recognized for almost a decade. FPL has been the recipient of the Tree Line USA award annually from 2003 - 2010. This award is sponsored by the Arbor Day Foundation in cooperation with the National Association of State Foresters. The recognition is given to utilities that demonstrate quality tree care practices, annual worker training, and public education programs.

In October 2010, FPL won the 2010 Loggerhead Marinelife Center's "Blue Business of the Year" award. The awards were given to those who are leading the way in raising awareness and have made significant contributions to improve and protect South Florida's oceans, beaches, and wildlife. The award recognized FPL's protection and conservation of the endangered Florida manatee and fostering public and employee education and support.

The 12th Annual Sustainable Florida Best Practice Awards were announced on June 4, 2010 in Orlando, Florida. FPL was named a finalist in the large business category for the previously mentioned 25 MW DeSoto PV facility. The awards were presented by the Council for Sustainable Florida, the premier statewide organization committed to balancing the economic interests of the state with the need to be socially and environmentally responsible. The Sustainable Florida Award recognizes organizations for protecting and preserving Florida's environment for the future while building markets for Florida's business.

In December 2009, Next Era Energy was named Power Company of the Year at the Platts 2009 Global Energy Awards. Platts, the leading global provider of information on the energy industry, received more than 200 nominations for its annual awards program. Nominations came from more than 30 countries. FPL Group was selected as Power Company of the Year from among six finalists. The specific judging criteria were financial results, operational excellence, innovation, and strategic vision.

As mentioned above, NextEra Energy, Inc. has taken a leadership role to address climate change and the call for action for a national climate change policy. The decision to step into the forefront of this issue goes hand-in-hand with NextEra Energy, Inc.'s longtime commitment to managing operations with sensitivity to the environment.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define its position, which it continues to stand by today. This statement reflects how FPL incorporates environmental values into all aspects of its activities and serves as a framework for new environmental initiatives throughout the company. FPL's Environmental Statement is:

> It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:
>
> - Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
> - Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
> - Encourage the wise use of energy to minimize the impact on the environment.
> - Communicate effectively on environmental issues.
> - Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, a dedicated environmental corporate governance program, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident and/or emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with corporate policy as well as legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and FPL policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2010 environmental outreach activities are noted below in Table IV.E.1. In 2009 and 2010, FPL launched web cams at four facilities in order to increase public awareness of ongoing solar projects, FPL's commitment to sea turtle rehabilitiation, and the warm water refuge for manatees provided by power plants. The "solar cams" provide the public with a glimpse of the PV installation at the Space Coast Next Generation Solar Energy Center and the solar thermal installation at the Martin Next Generation Solar Energy Center. The "turtle cam" installed at the Loggerhead Marinelife Center in Juno Beach provides interested onlookers the opportunity to view rescued sea turtles as they are nursed back to health in the sea turtle hospital. Additionally, the "manatee cam" provides the public a glimpse of hundreds of manatees that gather in the warm waters near the FPL Riviera Plant each Winter during the cold weather. These web cam addresses, respectively, are:

http://www.fpl.com/environment/solar/spacecoast_cam.shtml,
http://www.fpl.com/environment/solar/martin_cam.shtml,
http://www.fpl.com/environment/plant/turtle_cam.shtml, and,
http://www.fpl.com/environment/plant/riviera_cam.shtml.

In 2010, FPL, in partnership with the Treasured Lands Foundation, officially re-opened the Barley Barber Swamp at the Martin Power Plant for public tours. The tours began in November of 2010.

Table IV.E.1: 2010 FPL Environmental Outreach Activities

Activity	# of Participants (Approx.)
Visitors to FPL's Energy Encounter at St. Lucie	17,000
Visitors to Manatee Park	272,243
Number of visits to FPL's Environmental Website	400,000
Number of pieces of Environmental literature distributed	>60,000
Solar Schools Program (# of schools participating)	8 (6 new in 2010)
Visitors to Barley Barber Swamp	943
Number of visits to Manatee Cam Website	45,000
Number of visits to Turtle Cam Website	36,000
Number of visits to Space Coast WebCam Website	500
Number of visits to Martin WebCam Website	1,500

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified five (5) Preferred Sites and thirteen (13) Potential Sites for future generation additions. Preferred Sites are those locations where FPL has conducted significant reviews and has either taken action, or is currently committed to take action, to site new generation capacity. Potential Sites are those sites that have attributes that support the siting of generation and are under consideration as a location for future generation. Some of these sites are currently in use as existing generation sites and some are not. The identification of a Potential Site does not indicate that FPL has made a definitive decision to pursue generation (or generation expansion in the case of an existing generation site) at that location, nor does this designation indicate that the size or technology of a generator has been determined. The Preferred Sites and Potential Sites are discussed in separate sections below.

As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include all of the remainder of FPL's existing generation sites and other Greenfield sites. FPL is also analyzing the potential for modernizing existing power plant sites such as is now being done at the Cape Canaveral and Riviera sites. For example, the existing Port Everglades site is a potential site for modernization. Other existing sites may also emerge in the ongoing analyses as potential candidates for modernization. Analyses of any modernization candidates would include evaluation of numerous factors including: fuel delivery, transmission, permitting, etc.

IV.F.1 Preferred Sites

FPL identifies five Preferred Sites in this Site Plan: the existing West County Energy Center (WCEC) site, the existing St. Lucie plant site, the existing Turkey Point plant site, the existing Cape Canaveral plant site, and the existing Riviera plant site.

The West County Energy Center site is the location for one combined cycle (CC) capacity addition FPL will make in 2011. The St. Lucie site is the location for nuclear capacity uprates that FPL will make in 2011 and 2012. The Turkey Point site is the location for nuclear capacity uprates that FPL will make in 2012 and 2013. (Turkey Point is also the site for two new nuclear units, Turkey Point Units 6 & 7, for which FPL is pursuing licensing and permit approvals. Current projections for in-service dates these new nuclear units are beyond the 2011-2020 reporting time frame of this document). The Cape Canaveral and Riviera sites are the locations for modernizations of existing power plant sites for capacity additions in 2013 and 2014, respectively.

The five Preferred Sites are discussed below in general chronological order in regard to when the capacity additions are projected to occur.

Preferred Site # 1: West County Energy Center, Palm Beach County

FPL has identified the property adjacent to the existing Corbett Substation property in unincorporated western Palm Beach County as a Preferred Site for the further addition of new generating capacity. The site was selected for the addition of another CC natural gas unit (Unit 3) with ultra-low sulfur light fuel oil (distillate) as a backup fuel. WCEC Units 1 & 2 were constructed on this site and went into commercial operations on August 27, 2009, and November 3, 2009, respectively. WCEC Unit 3, which began construction in March 2009, was approved by both the FPSC and the Secretary of the Florida Department of Environmental Protection (FDEP) and is anticipated to go into commercial operation in June of 2011. Unit 3 will be identical to Units 1 & 2 in regard to technology and capacity.

The existing site is accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections. The facility will use natural gas as the primary fuel and state-of-the-art combustion controls.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the West County Energy Center (WCEC) plant site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the WCEC generating facilities at the site is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

The site was undeveloped until February 2007 when construction of WCEC Units 1 & 2 was initiated. The site was previously dedicated to industrial (mining) and agricultural use. The site had been excavated, back-filled, and totally re-graded to an elevation of approximately 10 feet above the surrounding land surface. Prior to the initiation of power plant construction, no structures were present on the site and vegetation was virtually non-existent. Units 1 & 2 are completed and are now in commercial operation.

e. **General Environment Features On and In the Site Vicinity**

1. **Natural Environment**

The plant site had been significantly altered by the construction and operation of a limestone mine where vegetation had been cleared and removed. The surrounding land use is predominantly sugar cane, agriculture, and limestone mining. FPL's existing Corbett substation is located north of the site. The Arthur R. Marshall Loxahatchee National Wildlife Refuge is located to the south of the site.

2. **Listed Species**

Construction and operation of Unit 3 at the site will not affect any rare, endangered, or threatened species. Wildlife utilization of the property is minimal as a result of the prior mining activities. Common wading birds can be observed on areas adjacent to, and occasionally within, the property. The property is adjacent to areas that have been identified as potential habitats for wood stork.

3. **Natural Resources of Regional Significance Status**

The construction and operation of another gas-fired CC generating facility at this location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands including the Arthur R. Marshall Loxahatchee National Wildlife Refuge. Construction will not result in any onsite wetland impacts under federal, state, or local agency permitting criteria.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design of Unit 3 comprises the following: one 1,219 MW (Summer capacity) unit consisting of: three combustion turbines (CT), three heat recovery steam generators (HRSG), and a new steam turbine. Natural gas delivered via pipeline is the primary fuel type for this facility with ultra-low sulfur light fuel oil (distillate) serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the project site is "Rural Residential" according to the Palm Beach County Future Land Use Map.

Designations for the area under the Palm Beach County Unified Land Development Code classified the project site and surrounding area as Special Agricultural District. The site has been granted conditional use for electrical power facilities under a General Industrial zoning district.

h. Site Selection Criteria Process

The site has been selected as a Preferred Site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues.

i. Water Resources

The primary water source for the entire site is reclaimed (reuse) water from Palm Beach County Water Utilities Department. Reclaimed water is being used for cooling, service, and process water for Units 1 and 2 and as start-up water for Unit 3. Backup water sources include utilizing the Floridan Aquifer allocation permitted for WCEC Units 1, 2, & 3. Potable water is purchased from the Palm Beach County water municipality.

j. Geological Features of Site and Adjacent Areas

The site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks. Little information is known about these rocks due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, clay, and phosphate grains. The deepest formation in Palm Beach County on which significant published data are available is the Eocene Age Avon Park.

Testing during construction of Exploratory Well 2 (EW-2) demonstrated the presence of a highly permeable zone (Boulder Zone) in the Oldsmar Formation below a depth of 2,790 feet below pad level (bpl) overlain by a thick confining interval (Avon Park Formation) from approximately 2,000 to 2,790 feet bpl. The base of the Underground Source of Drinking Water (USDW) was identified between the depths of 1,932 and 1,959 feet bpl through interpretation of packer tests, water quality data, and geophysical logs. Injection testing confirmed that the hydrogeology of the EW-2 site is favorable for disposal of fluids via a deep injection well system. FPL converted EW-2 to an injection well and installed a second injection well (IW-1 and IW-2, respectively). FPL conducted operational testing on the wells and applied for an operational permit. FDEP has issued a Notice of Intent to issue a Class I operational permit for the two injections wells and the associated dual-zone monitoring well.

k. Projected Water Quantities for Various Uses

The estimated annual average quantity of water required for industrial processing and cooling for all 3 units is up to 29 million gallons per day (mgd). Cooling water for the three generating units would be cycled through cooling towers.

l. Water Supply Sources by Type

WCEC Units 1 & 2, and eventually Unit 3, will use reclaimed water as the primary source of cooling water for the cooling tower with the Floridan Aquifer as backup. The cooling tower will also act as a heat sink for the facility auxiliary cooling system. Such needs for cooling and process water will comply with the existing South Florida Water Management District (SFWMD) regulations for consumptive water use. In addition, reclaimed water used at WCEC must meet all relevant requirements of Chapter 62-610, F.A.C., Part III, for use in cooling towers.

m. Water Conservation Strategies Under Consideration

The use of reclaimed water is a water conservation strategy because it is a beneficial use of wastewater. Impacts on the surficial aquifer would be minimized and used only for potable water, if necessary. Water from the Floridan Aquifer will be used for cooling purposes as a backup water source and cooling towers will be utilized. In addition, captured storm water may be reused in the cooling tower whenever feasible. Storm water captured in the storm water ponds will also recharge the surficial aquifer.

n. Water Discharges and Pollution Control

Heat will be dissipated in the cooling towers. Blowdown water from the cooling towers, along with other waste streams, will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. In addition, captured storm water may be reused in the cooling towers, whenever feasible. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is serviced by a new natural gas transmission pipeline that is capable of providing a sufficient quantity of gas to the entire site. Ultra-low sulfur light fuel oil (distillate) will be received by truck and stored in above-ground storage tanks to serve as backup fuel for the WCEC generating units.

p. Air Emissions and Control Systems

The use of natural gas and ultra-low sulfur light fuel oil (distillate) and combustion controls will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminants. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil (distillate) as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. In total, the designs of the WCEC generating units incorporate features that will make the units among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by construction at the site is expected to be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will be within allowable levels.

r. Status of Applications

In regard to WCEC Unit 3, a Site Certification Application (SCA) was filed in December 2007 and the unit received Site Certification by the Secretary of the FDEP, in lieu of the Governor and Cabinet, in November 2008. A Prevention of Significant Deterioration (PSD) air permit was filed in December 2007. The permit was issued by FDEP in July 2008. FPL initiated construction in March 2009 and anticipates an in-service date of June 2011. WCEC Unit 3 will utilize the underground injection control (UIC) system permitted for the entire site.

Preferred Site # 2: St. Lucie Plant, St. Lucie County

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The plant site is bordered by the Atlantic Ocean to the east and the Indian River Lagoon to the west. Located on the site are two nuclear-powered generating units, St. Lucie Units 1 & 2, which have been in operation since 1976 and 1983, respectively.

The generating capacity addition is an increase in the capacity of the two existing nuclear generating units that is used to serve FPL's customers of approximately 122 MW for St. Lucie Unit 1 and 110 MW for St. Lucie Unit 2. The difference between the two values is due to FPL's 100% ownership share of St. Lucie 1 and its 85% ownership share of St. Lucie Unit 2. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing Turkey Point nuclear units, was approved by the FPSC in January 2008. The capacity uprates at St. Lucie for the two nuclear units sited there are projected to be in-service partially beginning in 2011 and in their entirety in 2012.[4]

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the FPL St. Lucie Nuclear site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the proposed generating facilities at the site is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

[4] FPL has also been pursuing the addition of six wind turbines at the St. Lucie plant site for a number of years. However, to-date FPL has been unable to obtain the necessary local land use approvals that would first be needed before state and federal approvals could be sought.

d. Existing Land Uses of Site and Adjacent Areas

St. Lucie Units 1 & 2 are pressurized water reactors, each having two steam generators. The prominent structures, enclosed facilities, and equipment associated with St. Lucie Units 1 & 2 include the containment building, the turbine generator building, the auxiliary building, and the fuel handling building.

Prominent features beyond the power block area include the intake and discharge canals, switchyard, spent-fuel storage facilities, technical and administrative support facilities, and public education facilities (the Energy Encounter and the College of Turtle Knowledge). Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay, and Indian River Lagoon.

In regard to the nuclear capacity uprates, the only changes will be modifications to the existing power generation facilities within the power block area, modifications to the switchyard facilities, and modifications to the transmission lines from St. Lucie to Midway substation. None of the other existing facilities at the plant will change as a result of the uprates.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

FPL's St. Lucie Plant is located in St. Lucie County on Hutchinson Island on an FPL-owned 1,130-acre site. The St. Lucie Plant includes the reactor buildings, turbine buildings, access/security building, auxiliary building, maintenance facilities, and miscellaneous warehouses and other buildings associated with the operation of Units 1 & 2. The site includes adjacent undeveloped mangrove areas. As a result of the approved capacity uprates, the site characteristics will not change.

2. Listed Species

Some listed species known to occur in the area of the plant location are Atlantic sturgeon, smalltooth sawfish, loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas)*, leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtle (*Eretmochelys imbriccata*), gopher tortoise (*Gopherus polyphemus*), kemp's ridley sea turtle (*Lepidochelys kempi*), wood stork (*Mycteria americana*), black skimmer (*Rynchops niger*), and least tern (*Sterna antillarum*).

In regard to the nuclear capacity uprates, neither the development work, nor the continued operation of the two nuclear units after the uprate work has been completed, are expected to adversely affect any rare, endangered, or threatened species. No changes in wildlife populations at the adjacent undeveloped areas are anticipated, including listed species. Noise and lighting impacts will not change and it is expected that wildlife will continue to use the undeveloped areas within the St. Lucie Plant boundary.

3. **Natural Resources of Regional Significance Status**

Significant features surrounding the St. Lucie Units 1 & 2 are predominately undeveloped land and water bodies including; Big Mud Creek, the Atlantic Ocean, Herman's Bay, and Indian River Lagoon.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. The cooling system for the two generating units is a once-through system. The effects of the discharge of cooling water via these discharge structures were evaluated and mixing zones were established to allow compliance with thermal water quality standards as a part of the Plant's NPDES (Permit No. FL0002208). These mixing zones include the volume of water beyond the discharge structures, at the edge of which the water temperature is no greater than 17F abov e the ambient temperature of the intake water.

In regard to the nuclear capacity uprates, the once-through cooling system will continue to be used for the nuclear units.

g. **Local Government Future Land Use Designations**

St. Lucie Units 1 & 2 are located in unincorporated St. Lucie County, Florida. The County has adopted a comprehensive plan, which is updated on a periodic basis. The County Comprehensive Plan incorporates a map that depicts the future land use categories of all property falling within the unincorporated portions of the County. The St. Lucie Plant has a Future Land Use category of Transportation/Utilities (T/U) according to the St. Lucie County Future Land Use Map. The T/U category is described in the St. Lucie County Comprehensive Plan Future Land Use Element Future Land Use.

h. Site Selection Criteria Process

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity.

i. Water Resources

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. The once-through cooling system flow will not change as a result of the nuclear uprates. Due to the existing nature of the St. Lucie Plant, surrounding surface waters will not be adversely affected by the generation capacity addition. Stormwater will be handled by the existing facilities and no new areas will be impacted. Wetlands, groundwater, and nearby surface waters will not be impacted.

j. Geological Features of Site and Adjacent Areas

Beneath the land surface, there is a peat layer 4 to 6 feet thick. Below this layer is the Anastasia Formation, a sedimentary rock formation composed of clay lenses, sandy limestone, and silty fine to medium sand with fragmented shells. This highly permeable stratum extends 35 to 90 feet below mean sea level (msl). Underlying this stratum there is a semi-permeable zone, The Hawthorn Formation, consisting of slightly clayey and very fine silt which extends 600 feet below msl.

The original surficial deposits at the St. Lucie Plant were excavated to a depth of 60 feet and backfilled with Category I or II fill. The fill is underlain by the Anastasia formation, a sequence of partially cemented sand and sandy limestone, which extends to an average depth of about 145 feet. The Anastasia is underlain to a depth of about 600 to 700 feet by the partially cemented and indurated sands, clays, and sandy limestones of The Hawthorn Formation. Underlying these surface strata are about 13,000 feet of Jurassic through Tertiary Formations, primarily carbonate rocks. These formations have a relatively gentle slope to the southeast.

k. Projected Water Quantities for Various Uses

No change is expected in the quantity or characteristics of industrial wastewaters generated by the facility. Therefore, no change in that compliance achievement status is expected. The capacity uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The St. Lucie Plant does not directly withdraw groundwater under its current operations and it will not withdraw groundwater after the capacity uprates work is completed. The use of water supplied by the City of Fort Pierce, which does withdraw groundwater, will remain unchanged and there will be no changes to the groundwater discharges. There will be no quality, quantity, or hydrological changes, either by withdrawal or discharge to a drinking water source. Therefore, there will be no impacts on drinking water.

l. **Water Supply Sources by Type**

The source of cooling water for the St. Lucie Plant is the Atlantic Ocean. General plant service water, fire protection water, process water, and potable water are obtained from City of Fort Pierce. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns. The existing St. Lucie Plant water use is projected to be unchanged as a result of the nuclear capacity uprates.

m. **Water Conservation Strategies Under Consideration**

The existing water resources will not change as a result of the nuclear capacity uprates.

n. **Water Discharges and Pollution Control**

St. Lucie Units 1 & 2 use once-through cooling water from the Atlantic Ocean to remove heat from the main (turbine) condensers via the Circulating Water System (CWS), and to remove heat from other auxiliary equipment via the Auxiliary Equipment Cooling Water System (AECWS). The great majority of this cooling water is used for the CWS.

Under emergency conditions, water can be withdrawn from Big Mud Creek via the Emergency Intake Canal through two 54-inch pipe assemblies in the barrier wall that separates the Creek from the Canal. FPL does not use this intake during normal operations, but does test this system quarterly.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

St. Lucie Units 1 & 2 are licensed for uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core. Each reactor core includes 217 fuel assemblies.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 47,000 megawatt-days per metric ton uranium. In regard to the nuclear capacity uprates, more nuclear fuel will be used due to the increased capacity of each generating unit. No changes in the fuel-handling facilities are required. Used fuel assemblies are stored in the onsite Nuclear Regulatory Commission (NRC) approved spent fuel storage facilities. Following completion of the uprates, approximately 11 percent more nuclear fuel will be used to increase the capacity of each generating unit. No changes in the fuel-handling facilities are required.

Diesel fuel is used in a number of emergency generators that include four main plant generators, two building generators, and various general purpose diesel engines. The main plant emergency generators will not be changed as a result of the generation capacity additions. These emergency generators are for standby use only and are tested to assure reliability and for maintenance. Diesel fuel is delivered to the St. Lucie Plant by truck as needed, and stored in tanks with secondary containment.

p. Air Emissions and Control Systems

The St. Lucie Plant is classified as a minor source of air pollution, since FDEP has issued a Federally Enforceable State Operating Permit (FESOP) to keep emissions less than 100 tons per year for any air pollutant regulated under the Clean Air Act. The applicable units at the St. Lucie Plant consist of eight large main plant diesel engines, two smaller diesel engines, and various general-purpose diesel engines. The air emissions from these engines are limited by the use of 0.05-percent sulfur diesel fuel and good combustion practices. Best Available Control Technology (BACT) is not applicable to these existing emission units.

Nitrogen oxide (NO_x) emissions from the operation of the diesel engines comprise the limiting pollutant for these diesel units at the St Lucie Plant. The FDEP FESOP limits

NO_x emissions to 99.4 tons, which includes fuel use limits on the large main plant emergency diesel engines of 97,000 gallons in any 12-month consecutive period and the smaller building and general purpose diesel engines of 190,000 gallons in any 12-month consecutive period. Also, the Plant may choose to combine the diesel units' fuel-tracking, which then limits the NO_x totals for a 12-month consecutive period to a maximum of 80 tons. There will be no change in the operation or emissions of the diesel engines resulting from the nuclear capacity uprates.

In addition, the generation capacity additions will not result in an increase of CO_2 or other greenhouse gas emissions. In fact, the increases in generation capacity are projected to result in decreased FPL system-wide emissions of CO_2.

q. **Noise Emissions and Control Systems**

A field survey and impact assessment of noise expected to be caused by construction activities at the site was conducted. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site during construction or operation.

r. **Status of Applications**

A Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in December 2007 and a final order issued in September 2008. The FPSC voted to approve the need for the St. Lucie (and Turkey Point) nuclear capacity uprates and the final order approving the need for these capacity additions was issued in January 2008.

Preferred Site # 3: Turkey Point Plant, Miami-Dade County

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear units (Units 3 & 4), two natural gas/oil conventional steam units (Units 1 & 2), one CC natural gas unit (Unit 5), nine small diesel generators, the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the Everglades Mitigation Bank (EMB).

Turkey Point Units 3 & 4 have been in operation since 1972 and 1973, respectively. The Turkey Point site has been selected as a Preferred Site for the increase in the capacity of its two existing nuclear generating units by approximately 109 MW each. This work will involve changes to several existing main components within the existing facilities to increase their capability to produce steam for the generation of electricity. No new or expanded facilities are required as part of this capacity "uprate." This capacity uprate, along with a similar capacity uprate of FPL's existing St. Lucie nuclear units, was approved by the FPSC in January 2008. The capacity uprates at Turkey Point are projected to be in-service in 2012 and early 2013.

As previously mentioned, FPL is pursuing licensing for two new nuclear units at the Turkey Point site. Each of these two units would provide 1,100 MW of capacity. Current projections for the in-service dates of these two units, Turkey Point Units 6 & 7, are beyond the 2011 - 2020 reporting time frame of this document.

a. <u>U.S. Geological Survey (USGS) Map</u>

A USGS map of the Turkey Point plant site is found at the end of this chapter.

b. <u>Proposed Facilities Layout</u>

A map of the general layout of the Turkey Point Units 3 and 4 generating facility at the site is found at the end of this chapter.

c. <u>*Map of Site and Adjacent Areas*</u>

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. <u>Existing Land Uses of Site and Adjacent Areas</u>

The five existing power generation units and support facilities occupy approximately 150 acres of the 11,000-acre Turkey Point Plant site. Support facilities include service buildings, an administration building, fuel oil tanks, water treatment facilities, circulating water intake and outfall structures, wastewater treatment basins, and a system substation. The cooling canal system occupies approximately 5,900 acres. The two 400-megawatt (MW) (nominal) fossil fuel-fired steam electric generation units at the Turkey Point Plant have been in service since 1967 (Unit 1) and 1968 (Unit 2). These units currently burn residual fuel oil and/or natural gas with a maximum equivalent sulfur content of 1 percent. The two 700-MW (nominal) nuclear units have been in service since 1972 (Unit 3) and 1973 (Unit 4). Turkey Point Units 3 and 4 are pressurized water reactor (PWR) units. Turkey Point Unit 5 is a nominal 1,150-MW natural gas-fired combined cycle (CC) unit that began operation in 2007. Significant features in the vicinity of the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The prominent structures and enclosed facilities and equipment associated with Units 3 & 4 include: the containment building, which contains the nuclear steam supply system including the reactor, steam generators, reactor coolant pumps, and related equipment; the turbine generator building, where the turbine generator and associated main condensers are located; the auxiliary building, which contains waste management facilities, engineered safety components, and other facilities; and the fuel handling building, where the spent fuel storage pool and storage facilities for new fuel are located. Prominent features beyond the power block area include the intake system, cooling canal system, switchyard, spent fuel storage facilities, and technical and administrative support facilities.

2. Listed Species

The construction during the uprating of the units, and operation of the units after the capacity uprating is completed, are not expected to adversely affect any rare, endangered, or threatened species. Listed species known to occur at the site and in the nearby Biscayne National Park that could potentially utilize the site include the peregrine falcon *(Falco peregrinus)*, wood stork *(Mycteria americana)*, American crocodile *(Crocodylus acutus)*, mangrove rivulus *(Rivulus marmoratus)*, roseate spoonbill *(Ajaja ajaja)*, limpkin *(Aramus guarauna)*, little blue heron *(Egretta caerulea)*, snowy egret *(Egretta thula)*, American oystercatcher *(Haematopus palliates)*, least tern *(Sterna antillarum)*, the white ibis *(Eudocimus albus)*, and bald eagle *(Haliaeetus leucocephalus)*. No bald eagle nests are known to exist in the vicinity of the site. The federally listed, threatened American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American crocodile and is attributed with survival improvement and the downlisting of the American Crocodile from endangered to threatened.

3. Natural Resources of Regional Significance Status

Significant features in the vicinity on the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park. Biscayne National Park contains 180,000 acres, approximately 95 percent of which is open water interspersed with more than 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant and is adjacent to the Miami-Dade County Homestead Bayfront Park which contains a marina and day-use recreational facilities.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

Turkey Point Units 3 & 4 uses cooling water from a closed-cycle cooling canal system to remove heat from the main (turbine) condensers, and to remove heat from other auxiliary equipment. The existing cooling canals will accommodate the increase in heat load that is associated with the increased capacity from the uprates. The maximum projected increase in water temperature entering the cooling canal system from the units resulting from the uprates is predicted to be about 2.5F, from 106.1F to 108.6F. The associated projected ma ximum increase in water temperature returning to the units is about 0.9F, from 91.9F to 92.8F.

g. Local Government future Land Use Designations

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. Site Selection Criteria Process

The site has been selected as a Preferred Site for the nuclear capacity uprates because it is an existing nuclear plant site and, therefore, offers the opportunity for increased nuclear capacity.

i. **Water Resources**

Unique to the Turkey Point plant site is the self-contained cooling canal system that supplies water to condense steam used by the plant's turbine generators. The canal system consists of 36 interconnected canals. The cooling canals occupy an area approximately two miles wide by five miles long (5,900 acres), approximately four feet deep. The system performs the same function as a giant radiator. The water is circulated through the canals in a two-day journey, ending at the plant's intake pumps.

j. **Geological Features of Site and Adjacent Areas**

The Turkey Point Plant lies upon the Floridian Plateau, a partly-submerged peninsula of the continental shelf. The peninsula is underlain by approximately 4,000 to 15,000 feet of sedimentary rocks consisting of limestone and associated formations that range in age from Paleozoic to Recent. Little is known about the basement complex of Paleozoic igneous and metamorphic rocks due to their great depth.

Generally in Miami-Dade County, the surficial aquifer (Biscayne Aquifer) consists of a wedge-shaped system of porous clastic and carbonate sedimentary materials, primarily limestone and sand deposits of the Miocene to late Quaternary age. The Biscayne Aquifer is thickest along the eastern coast and varies in thickness from 80 to 200 feet thick. The surficial aquifer is typically composed of Pamlico Sand, Miami Limestone (Oolite), the Fort Thompson and Anastasia Formations (lateral equivalents), Caloosahatchee Marl, and the Tamiami formation. The lower confining layers below the surficial aquifer range in thickness from 350 to 600 feet and are composed of the Hawthorn Group. Beneath the Hawthorn Group, the Floridan Aquifer System ranges from 2,800 to 3,400 feet thick and consists of Suwannee Limestone, Avon Park Limestone, and the Oldsmar Formations.

k. **Projected Water Quantities for Various Uses**

The addition of nuclear generating capacity as a result of the uprates will not cause any changes in the quantity or characteristics of industrial wastewaters generated by the facility; therefore, no change in that compliance achievement status is expected. The uprates will not cause any changes in hydrologic or water quality conditions due to diversion, interception, or additions to surface water flow. The Turkey Point Plant does not directly withdraw groundwater under its current operations and it will not do so after the capacity uprates. Locally, groundwater is present beneath the site in the surficial or Biscayne Aquifer and in deeper aquifer zones that are part of the Floridan

Aquifer System. There will be no effects on those deeper aquifer zones from the capacity uprates.

l. Water Supply Sources and Type

The source of cooling water for Turkey Point Units 3 & 4 is the cooling canal system. There will be no increase in the amount of water withdrawn as a result of the capacity uprates. General plant service water, fire protection water, process water, and potable water are obtained from Miami-Dade County. Process water uses include demineralizer regeneration, steam cycle makeup, and general service water use for washdowns. The water use for the facility will not change as a result of the capacity uprates.

m. Water Conservation Strategies

The existing water resources will not change as a result of the uprates.

n. Water Discharges and Pollution Control

Heated water discharges are dissipated using the existing closed cooling canal system.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Turkey Point Units 3 & 4 utilize uranium-dioxide fuel that is slightly enriched uranium-235. The uranium-dioxide fuel is in the form of pellets contained in Zircaloy tubes with welded end plugs to confine radionuclides. The tubes are fabricated into assemblies designed for loading into the reactor core. Used fuel assemblies are stored in the onsite NRC-approved spent fuel storage facilities.

FPL currently replaces approximately one-third of the fuel assemblies in each reactor at refueling intervals of approximately 18 months. FPL operates the reactors such that the average fuel usage by the reactors is approximately 45,000 megawatt-days per metric ton of uranium. Following completion of the uprates, more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel handling facilities are required. Following completion of the uprates, approximately 11 percent more nuclear fuel will be used to increase the capacity of each unit. No changes in the fuel-handling facilities are required.

Diesel fuel is used in a number of emergency generators that include four main emergency generators, five smaller emergency generators, and various general purpose diesel engines. The emergency generators will not be changed as a result of the capacity uprates. These emergency generators are for stand-by use only and only operated for testing purposes to assure reliability and for maintenance. Diesel fuel for the emergency generators is delivered to the Turkey Point Plant by truck as needed, and stored in tanks with secondary containment.

p. Air Emissions and Control Systems

The normal operation of Turkey Point Units 3 & 4 does not create fossil fuel-related air emissions. However, there are nine emergency generators associated with Units 3 & 4. Four of these nine emergency generators are main plant emergency generators which are rated at 2.5 MW each. The remaining five generators are smaller emergency generators which are associated with the security system. In addition, various general purpose diesels are used as needed for Units 3 & 4.

Turkey Point Plant Units 3 & 4's associated emergency generators and diesel engines, together with Units 1, 2, & 5, are classified as a major source of air pollution. FDEP has issued a separate Title V Air Operating Permit for the Turkey Point Nuclear Plant (Permit Number 0250003-004-AV). There are no operating limits for the emergency generators or diesel engines. Emergency diesel generators are limited to ultra-low sulfur distillate (0.0015% sulfur). NOx emissions are regulated under Reasonably Available Control Technology (RACT) requirements in Rule 62-296.570(4)(b)7 F.A.C., which limit NO_x emissions to 4.75 lb/MMBtu. The use of 0.05 percent sulfur diesel fuel and good combustion practices serve to keep NO_x emissions under this limit.

q. Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by activities associated with the uprates was conducted. Predicted noise levels are not expected to result in adverse noise impacts in the vicinity of the site.

r. **Status of Applications**

A Site Certification Application (SCA) under the Florida Electrical Power Plant Siting Act was filed in January 2008 and a final order was issued in October 2008. The FPSC voted to approve the need for the Turkey Point (and St. Lucie) uprates and the final order approving the need for this additional nuclear capacity was issued in January 2008.

Preferred Site # 4: Cape Canaveral Plant, Brevard County

This site is located on the existing FPL Cape Canaveral Plant property in unincorporated Brevard County. The site is bound to the east by the Indian River Lagoon and on the west by a four lane highway (US. 1). The city of Port St. Johns is located less than a mile away. A rail line is located near the plant.

The site previously housed two steam units (Units 1 & 2) with 788 MW (summer) of generating capacity. The units formerly occupied a portion of the 43 acres that are wholly owned by FPL. The units have been taken out of service and dismantlement of the Cape Canaveral Plant began in mid-2010 and is expected to be complete by the end of first quarter 2011.

The Cape Canaveral Plant site has been listed as a Potential Site in previous FPL Site Plans for both CC and simple cycle combustion turbine (CT) generation options. FPL is in the process of modernizing the existing Cape Canaveral Plant, to be renamed the Cape Canaveral Next Generation Clean Energy Center (CCEC), by replacing the previous two steam generating units with a single modern, highly efficient, lower-emission next-generation clean energy center using the latest CC technology.

a. **Geological Survey (USGS) Map**

A USGS map of the CCEC site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A map of the general layout of the CCEC generating facilities at the site is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing and future land uses on the site are primarily dedicated to electrical generation; i.e., FPL's former Cape Canaveral Units 1 & 2 and the future CCEC unit. The existing land uses that are adjacent to the site consist of single- and multi-family residences to the south and southwest, commercial property to the northwest, utility systems to the west, and a private medical/office facility to the north.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The natural environment surrounding the site includes the Indian River Lagoon to the east and upland scrub, pine and hardwoods to the north and south. Vegetation with the approximately 45-acre offsite construction laydown and parking area (located west of U.S. Highway 1) consists of open land, upland scrub, pine, hardwoods along with exotic plant species.

2. Listed Species

No adverse impacts to federally or state-listed terrestrial plants and animals are expected in association with construction at the site, due to the existing developed nature of the site and lack of suitable onsite habitat for listed species. Federal- or state-listed terrestrial plants and animals inhabiting the offsite construction laydown and parking area are limited to the state-listed gopher tortoise and the state- and federally-listed scrub jay. The warm water discharges from the plant attract manatees, an endangered species. FPL continues to work closely with state and federal wildlife agencies to ensure protection of the manatees during the modernization process and upon operation of the new plant. In 2010, FPL installed a temporary heating system to warm the water for the manatees as required during manatee season. FPL will also be complying with several other manatee-related conditions of certification to ensure the protection of the manatees during the modernization work.

3. Natural Resources of Regional Significance Status

The construction and operation of a natural gas-fired CC generating facility at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to replace the existing steam generating units (Units 1 & 2) with one new 1,210 MW (approximate) CC unit consisting of three new combustion turbines (CT), three new heat recovery steam generators (HRSG), and a new steam turbine. The new CC unit is projected to be in-service in mid-2013. Natural gas delivered via pipeline is the primary fuel type for this unit with ultra-low sulfur light oil serving as a backup fuel.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is "Public Utilities" and the area has been rezoned to GML-U. Designations for the surrounding area are primarily "Community Commercial" and "Residential".

h. Site Selection Criteria Process

The Cape Canaveral Plant has been selected for a site modernization due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. However, there are environmental benefits of replacing the previous steam units with a new CC unit including a significant reduction in system fuel use, a significant reduction in system air emissions, improved aesthetics at the site, and continued warm water discharge for the manatees as required during manatee season. Further, modernizing this existing facility reduces the impact on natural resources by not requiring new land, new water sources, or additional off-site transmission siting.

i. Water Resources

Condenser cooling for the steam cycle portion of the new plant and auxiliary cooling will come from the existing cooling water intake system. Process, potable, and irrigation water for the new plant will come from the existing City of Cocoa's potable water supply.

j. Geological Features of Site and Adjacent Areas

FPL's Cape Canaveral Plant is located on the Atlantic Coastal Ridge and is at an approximate elevation of 12 feet above mean sea level (msl). The land consists primarily of fine to medium sand that parallels the coast. There is a lack of shell as it was deposited during a time of transgression. The base of the sedimentary rocks is made up of a thick, primarily carbonate sequence deposited during the Jurassic age through the Pleistocene age. Starting in the Miocene age and continuing through the Holocene age, siliciclastic sedimentation became more predominant. The basement rocks in this area consist of low-grade metamorphic and igneous intrusives, which occur several thousand feet below land surface and are Precambrian, Paleozoic, and Mesozoic in age.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for processing is approximately 0.232 million gallons per day (mgd) for uses such as process water and service water. Approximately 619 mgd of cooling water would be cycled through the once-through cooling water system. Potable water demand is expected to average .001 mgd.

l. Water Supply Sources by Type

The modernized plant will continue to use the Indian River Lagoon water as the source of once-through cooling water. Such needs for cooling water will comply with the St. John's River Water Management District (SJRWMD) conditions of certification. Process and potable water for the new plant will come from the existing City of Cocoa's potable water supply. Reclaimed water will be used for irrigation.

m. Water Conservation Strategies Under Consideration

No additional water sources will be required as a result of the modernization project.

n. Water Discharges and Pollution Control

The modernized site will utilize portions of the existing once-through cooling water systems for heat dissipation. The heat recovery steam generator blowdown will be mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's once-through cooling water system. Stormwater runoff will be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for the new unit will be transported to the site via a pipeline. New off-site or on-site gas compressors will be installed to raise the gas pressure of the existing pipeline for the new unit. Ultra-low sulfur light fuel oil will be received by truck or barge from Port Canaveral and stored in an existing above-ground storage tank.

p. Air Emissions and Control Systems

The emission rates of CCEC would decrease by over 90% from the existing Cape Canaveral Plant, resulting in substantial annual emissions reductions and increased air quality benefits. The use of natural gas and ultra-low sulfur light fuel oil and combustion controls would minimize air emissions from the unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. In total, the design of the new CCEC plant will incorporate features that would make it among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise from the operation of the new unit will be within allowable levels.

r. Status of Applications

The FPSC voted to approve the need for the modernization project and the need order was issued in September 2008. The project received final state certification on October 9, 2009, through the issuance of a final order signed by the Secretary of the DEP.

Preferred Site # 5: Riviera Plant, Palm Beach County

This site is located on the existing FPL Riviera Plant property primarily within Riviera Beach, Palm Beach County (with a small portion of the Site in West Palm Beach). The site is bound to the east by the Lake Worth Lagoon (Intracoastal Waterway) and on the west by a four lane highway (US. 1). The site has barge access via the Port of Palm Beach. A rail line is located near the plant.

The previous site generating capacity was made up of two 300 MW (approximate) steam generating units (Units 3 & 4) that have been taken out of service and will be dismantled in 2011. Units 1 & 2 were previously retired and dismantled and are no longer on the plant site.

The Riviera Plant site has been listed as a Potential Site in previous FPL Site Plans for both CC and simple cycle combustion turbine (CT) generation options. FPL is in the process of modernizing the existing Riviera Plant, to be renamed the Riviera Beach Next Generation Clean Energy Center (RBEC), by replacing the existing generating units with a modern, highly efficient, lower-emission next-generation clean energy center using the latest CC technology. The existing two steam units will first be removed from the site and will be replaced by a single new CC unit.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the RBEC site is found at the end of this chapter.

b. **Proposed Facilities Layout**

A general layout of the RBEC generating facilities is found at the end of this chapter.

c. **Map of Site and Adjacent Areas**

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. **Existing Land Uses of Site and Adjacent Areas**

The previous Riviera Plant consisted of two 300 MW (approximate) units with conventional dual-fuel fired steam boilers and steam turbine units. The plant site includes minimal vegetation and a landscape buffer area south of the power plant. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the site is comprised of facilities related to electric power generation for the existing Riviera Plant generating units. The site is located adjacent to the Intracoastal waterway. The site provides warm water as required for manatees during manatee season.

2. Listed Species

No adverse impacts to federally or state-listed terrestrial plants and animals are expected in association with construction at the site, due to the existing developed nature of the site and lack of suitable onsite habitat for listed species. The warm water discharges from the plant attract manatees, an endangered species. FPL continues to work closely with state and federal wildlife agencies to ensure protection of the manatees during the modernization process and upon operation of the new plant. In 2009, FPL installed a temporary heating system to warm the water for the manatees as required during manatee season. FPL will also be complying with several other manatee-related conditions of certification to ensure the protection of the manatees during the modernization work.

3. Natural Resources of Regional Significance Status

The construction and operation of a natural gas-fired CC generating facility at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to replace the existing units (Units 3 & 4) with one new 1,212 MW (approximate) unit consisting of three new combustion turbines (CT), three new heat recovery steam generators (HRSG), and a new steam turbine. The new CC unit is projected to be in service in mid-2014. Natural gas delivered via pipeline is the primary fuel type for the unit with ultra-low sulfur light oil serving as a backup fuel.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the site is "Utility". The Port of Palm Beach is to the north of the site. Designation to the west of the site is "Commercial". To the south of the site is "Residential" and is in the City of West Palm Beach.

h. **Site Selection Criteria Process**

The Riviera plant has been selected for site modernization due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. However, there are environmental benefits of replacing the existing steam units with a new CC unit including a significant reduction in system air emissions, improved aesthetics at the site and continued warm water discharge for the manatees as required during manatee season. Further, modernizing this existing facility reduces the impact on natural resources by not requiring new land or new water sources.

i. **Water Resources**

Water from the Lake Worth Lagoon (Intracoastal waterway) is currently used for once-through cooling water. The new plant will utilize portions of the existing once-through cooling water intake and discharge structures. Water for cooling pump seals and irrigation will come from three onsite surficial aquifer wells. Process and potable water for the converted plant will come from the existing City of Riviera Beach potable water supply.

j. **Geological Features of Site and Adjacent Areas**

FPL's Riviera Plant site is underlain by the surficial aquifer system. The Surficial aquifer system in eastern Palm Beach County is primarily composed of sand, sandstone, shell, silt, calcareous clay (marl), and limestone deposited during the Pleistocene and Pliocene Epochs. The sediments forming the aquifer system are the Pamlico Sand, Fort Thompson Formation (Pleistocene) and the Caloosahatchee Marl (Pleistocene and Pliocene). Permeable sediments in the upper part of the Tamiami Formation (Pliocene) are also part of the aquifer system. The sediments in the eastern portion of the county are appreciably more permeable than in the west due to better sorting and less silt and clay content.

The surficial aquifer is underlain by at least 600 feet the Hawthorn formation (confining unit). The Floridan Aquifer System underlies the Hawthorn formation.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for processing is approximately 0.232 million gallons per day (mgd) for uses such as process water and service water. Approximately 600 mgd of cooling water would be cycled through the once-through cooling water system. Potable water demand is expected to average .001 mgd.

l. Water Supply Sources by Type

The modernized plant will continue to use the Lake Worth Lagoon water as the source of once-through cooling water. Water for cooling pump seals and irrigation will come from on-site surficial aquifer wells currently authorized under SFWMD conditions of certification. Process and potable water for the new plant will come from the existing City of Riviera Beach's potable water supply.

m. Water Conservation Strategies Under Consideration

No additional water sources will be required as a result of the modernization project.

n. Water Discharges and Pollution Control

The modernized plant will utilize portions of the existing once-through cooling water system for heat dissipation. The heat recovery steam generator blowdown will be mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's once-through cooling water system prior to discharge. Stormwater runoff will be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for the new unit would be transported to the site via an approximately 6 mile FPL-owned pipeline, the RBEC Lateral. New gas compressors will be installed at the existing FPL 45th Street Terminal facility in Riviera Beach to raise the gas pressure of the pipeline to the appropriate level for the new unit. Ultra-low sulfur light fuel oil would be received by truck, pipeline, or barge and stored in a new above-ground storage tank.

p. **Air Emissions and Control Systems**

The regulated air emissions at the new plant would be more than 90 percent lower than the previous Riviera Plant's emissions are, resulting in significant annual emissions reductions and air quality benefits. The use of natural gas and ultra-low sulfur light fuel oil and combustion controls would minimize air emissions from the unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of RBEC would incorporate features that will make it among the most efficient and cleanest power plants in the State of Florida.

q. **Noise Emissions and Control Systems**

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site.

r. **Status of Applications**

The FPSC voted to approve the need for the modernization project and the need order was issued in September 2008. The project received final state certification on November 24, 2009, through the issuance of a final order signed by the Secretary of the DEP. Final approval for the RBEC 6 mile pipeline lateral and compressor station is expected by end of March 2011.

IV.F.2 Potential Sites for Generating Options

Thirteen (13) sites are currently identified as Potential Sites for near-term future generation additions to meet FPL's projected capacity and energy needs.[5] These sites have been identified as Potential Sites due to considerations of location to FPL load

[5] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites and other Greenfield sites. Greenfield sites that FPL currently does not own, or for which FPL has not currently secured the necessary rights to, are not specifically identified as Potential Sites in order to protect the economic interests of FPL and its customers.

centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies, including both renewable energy and non-renewable energy technologies for various sites.

Each of these Potential Sites offer a range of considerations relative to engineering and/or costs associated with the construction and operation of feasible technologies. In addition, each Potential Site has different characteristics that will require further definition and attention. Solely for the purpose of estimating water requirements for sites more suited for non-renewable energy technologies, it was assumed that either one dual-fuel (natural gas and light oil) simple cycle CT or a natural gas-fired CC unit would be constructed at these Potential Sites unless otherwise noted.

A simple cycle CT would require approximately 50 gallons per minute (gpm) for both process and cooling water (assuming a cooling tower was utilized). A CC unit would require approximately up to 150 gpm for process water and up to 7.5 million gallons per day (mgd) per unit for cooling water (assuming a cooling tower is utilized). If an existing power plant site is ultimately selected for modernization (as is the case with FPL's Cape Canaveral and Riviera sites), the water requirements discussed above for a CC unit would be approximately correct for the modernized site. If a renewable energy generating technology is ultimately selected for one of these sites, the water requirements would be significantly less than those for CT or CC facilities.

Permits are presently considered to be obtainable for each of these sites. No significant environmental constraints are currently known for any of these sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time, FPL considers each site to be equally viable. As noted previously, FPL also considers a number of other sites as possible sites for future generation additions. These include all of the remainder of FPL's existing generation sites and other Greenfield sites.

Potential Site # 1: Babcock Ranch , Charlotte County

This site is located within the proposed Babcock Ranch Community on the north side of Tuckers Grade, approximately 10.5 miles north of the intersection of SR-80 and SR-31 and 1.1 miles east of SR-31. The project is bordered on the north by the Babcock Ranch Preserve owned by the State of Florida. The site is within the SFWMD and, therefore, the drainage would be in accordance with the SFWMD Basis of Review. Permitting of the surface water management system would be through the Florida Department of

Environmental Protection (FDEP) - South District. This site is a possibility for an FPL photovoltaic (PV) facility.

a. **U.S. Geological Survey (USGS) Map**

A map of this site is found at the end of this chapter.

b. **Land Uses**

Existing land use on the site is the Babcock Ranch Overlay District, and it is zoned as the Babcock Ranch Overlay Zoning District. This land use and zoning allows for solar facilities.

c. **Environmental Features**

FPL would anticipate mitigating for any panther and/or wetland impacts as a result of a PV project at this site.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility.

e. **Supply Sources**

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the solar panels in the absence of sufficient rainfall Any such water would be brought to the site by truck.

Potential Site # 2: DeSoto Solar Expansion, DeSoto County

The DeSoto site is located at 4051 Northeast Karson Street approximately 0.3 miles east of US 17 and immediately north of Bobay Road in Arcadia, Florida. The site is located in Sections 26, 27, & 35, Township 36 South, and Range 25 East. FPL owns an approximate 13,000 acre parcel in DeSoto County. FPL has designated approximately 5,177 acres for development of a photovoltaic (PV) facility.

The DeSoto site was previously selected as the site for the addition of a 25 MW PV facility, which is operational. There is also a potential to create an additional 275 MW PV generating facility which could be implemented in phases on the additional land.

a. **U.S. Geological Survey (USGS) Map**

A map of this site is found at the end of this chapter.

b. **Land Uses**

Existing land use on the site is agricultural. The future land use is Electric Generating Facility.

c. **Environmental Features**

There are no significant environmental features on the site.

d. **Water Quantities**

Minimal amounts of water would be required for a future expansion of the existing PV facility.

e. **Supply Sources**

Minimal water would be required at for an expanded PV facility. A small amount may be needed to occasionally clean the solar panels in the absence of sufficient rainfall and potable water will be required in the administration building and maintenance building. FPL would propose to utilize existing wells onsite to accommodate water needs.

Potential Site # 3: Florida Heartland, Glades County

This site is located within Glades County off of SR 78. This site is a possibility for an FPL PV facility.

a. **U.S. Geological Survey (USGS) Map**

A map of this site is found at the end of this chapter.

b. **Land Uses**

The existing land use on the site is agriculture.

c. **Environmental Features**

FPL would anticipate mitigating for any wildlife and/or wetland impacts as a result of a PV project at this site.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility.

e. **Supply Sources**

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water would be brought to the site by truck.

Potential Site # 4: Hendry County

FPL is currently evaluating potential sites in Hendry County for a future PV facility or fossil generation. Sites currently under investigation are approximately 1,500 acres. No specific locations have been selected at this time.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the county has been included at the end of this chapter.

b. **Land Uses**

Hendry County has predominantly agricultural land use.

c. **Environmental Features**

This information is not available because a specific site has not been selected at this time.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility. Fossil generation would require approximately up to 150 gallons per minute (gpm) for process water and up to 7.5 million gallons per day (mgd) per unit for cooling water (assuming a cooling tower is utilized).

e. **Supply Sources**

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. The supply of water for fossil generation would be dependent upon the selection of a specific site.

Potential Site # 5: Manatee Plant Site, Manatee County

The existing FPL Manatee Plant 9,500-acre site is located in unincorporated north-central Manatee County. The existing power generating facilities are located in all or portions of Sections 18 and 19 of Township 33S, Range 20-E. The plant site lies approximately 5 miles east of Parrish, Florida. It is approximately 5 miles east of U.S. 301 and 9.5 miles east of Interstate Highway 75 (I-75). The existing plant is approximately 2.5 miles south of the Hillsborough-Manatee County line; a portion of the north property boundary of the plant site abuts the county line. State Road 62 (SR 62) is about 0.7 mile south of the plant, with the plant entrance road going north from that highway. This site is a possible location for an FPL PV.facility.

a. **U.S. Geological Survey (USGS) Map**

A map of the site is found at the end of this chapter.

b. **Land Uses**

Existing land use on the site is agricultural. The property is zoned Planned Development / Public Interest (PD-PI), which will allow for electrical generation.

c. **Environmental Features**

FPL would anticipate mitigating for any wildlife and/or wetland impacts as a result of a PV project at this site.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility.

e. **Supply Sources**

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the solar panels in the absence of sufficient rainfall.

Potential Site # 6: Martin County

FPL is currently evaluating potential sites in Martin County for a future PV facility. No specific locations have been selected at this time.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the county has been included at the end of this chapter.

b. **Land Uses**

This information is not available because a specific site has not been selected at this time.

c. **Environmental Features**

This information is not available because a specific site has not been selected at this time.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility.

e. **Supply Sources**

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the solar panels in the absence of sufficient rainfall.

Potential Site # 7: Northeast Okeechobee County

FPL is currently evaluating potential sites in Northeast Okeechobee County for a future PV facility or fossil generation. Sites currently under investigation are approximately 1,500 acres. No specific locations have been selected at this time.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the county has been included at the end of this chapter.

b. **Land Uses**

Northeast Okeechobee County has predominantly agricultural land use.

c. **Environmental Features**

This information is not available because a specific site has not been selected at this time.

d. **Water Quantities**

As previously discussed, needed water quantities for fossil generation would be up to 150 gallons per minute (gpm) for process water and up to 7.5 million gallons per day (mgd) per unit for cooling water (assuming a cooling tower would be utilized). Needed water quantities would be significantly less for a PV facility.

e. **Supply Sources**

Existing groundwater and/or regional water supply initiatives are potential water sources.

Potential Site # 8: Palatka Site, Putnam County

FPL is currently evaluating a site adjacent to the FPL Putnam Plant in Putnam County for future fossil generation. The approximately 170 acre site was the location of the former FPL Palatka Plant which was dismantled in the 1990s.

a. **U.S. Geological Survey (USGS) Map**

A map of the site is found at the end of this chapter.

b. **Land Uses**

The site has a land use designation of Industrial.

c. **Environmental Features**

The majority of site has been previously impacted by past power plant operations. No significant environmental features have been identified at this time.

d. **Water Quantities**

As previously discussed, needed water quantities would be up to 150 gallons per minute (gpm) for process water and up to 7.5 million gallons per day (mgd) per unit for cooling water (assuming cooling tower).

e. **Supply Sources**

The St John's River, existing groundwater, and/or regional water supply initiatives are potential water sources.

Potential Site # 9: Port Everglades Plant, Broward County

The 94-acre FPL Port Everglades plant site is located at Port Everglades in Broward County. The site has convenient access to State Road (S.R.) 84 and I-595. Rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (approximate) and two 400 MW (approximate) sized units. The four steam boilers are capable of firing residual fuel oil, natural gas, or a combination of both. The site is also home to 12 simple cycle gas turbine (GT) peaking units of 35 MW (approximate) each. The GTs are capable of firing either natural gas or liquid fuel. This site is being considered for a potential modernization.

a. **U.S. Geological Survey (USGS) Map**

A map of the site is found at the end of this chapter.

b. **Land Uses**

The land on this site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

c. **Environmental Features**

The shoreline of the intake and discharge canal banks are vegetated with fringing mangrove, with some open, maintained grass areas on the side.

d. **Water Quantities**

Water quantities would be up to 150 gallons per minute (gpm) for process water and up to 7.5 million gallons per day (mgd) per unit for cooling water (assuming cooling tower).

e. **Supply Sources**

Existing groundwater or the municipal water supply could be used for industrial process and makeup water. Industrial cooling water needs could be met using the existing once-through cooling water system.

Potential Site # 10: Putnam County

FPL is currently evaluating potential sites in Putnam County for a future PV facility or fossil generation. Sites currently under investigation are approximately 2,800 acres. No specific locations have been selected at this time.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the county has been included at the end of this chapter.

b. **Land Uses**

Not available because a specific site has not been selected at this time.

c. **Environmental Features**

This information is not available because a specific site has not been selected at this time.

d. **Water Quantities**

Minimal amounts of water would be required for a PV facility. Fossil generation would require approximately up to 150 gallons per minute (gpm) for process water and up to

7.5 million gallons per day (mgd) per unit for cooling water (assuming a cooling tower is utilized).

e. **Supply Sources**

Existing groundwater is a potential water source.

Potential Site # 11: Southwest Indian River County

FPL is currently evaluating potential sites in Southwest Indian River County for a future PV facility or fossil generation. Sites currently under investigation are approximately 1,500 acres. No specific locations have been selected at this time.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the county has been included at the end of this chapter.

b. **Land Uses**

Southwestern Indian River County has predominantly agricultural land use.

c. **Environmental Features**

Not available because a specific site has not been selected at this time.

d. **Water Quantities**

As previously discussed, needed water quantities for fossil generation would be up to 150 gallons per minute (gpm) for process water and up to 7.5 million gallons per day (mgd) per unit for cooling water (assuming a cooling tower is utilized). Needed water quantities would be significantly less for a PV facility.

e. **Supply Sources**

Existing groundwater is a potential water source.

Potential Site # 12: Space Coast Solar Expansion, Brevard County

The Space Coast site is located at NASA's Kennedy Space Center property in Brevard County. This site currently consists of a 10 MW PV facility with the potential to expand by another 10 MW. Also, FPL is evaluating the potential for further expansion beyond the existing site, within the Space Center property.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the site has been included at the end of this chapter.

b. **Land Uses**

NASA, a federal agency, has approved use of the land at the site for PV generation.

c. **Environmental Features**

There are no significant environmental features on this site.

d. **Water Quantities**

Minimal amounts of water would be required for an expansion of the PV facility.

e. **Supply Sources**

No water would be required for an expansion of the PV facility except the small amount that may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water would be brought to the site by truck or would come from existing onsite wells.

Potential Site # 13: West Broward, Broward County

FPL has identified its Andytown Substation property in western unincorporated Broward County as a potential site for the addition of new fossil generating capacity and FPL refers to this potential site as the West Broward site. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. **U.S. Geological Survey (USGS) Map**

A USGS map of the county has been included at the end of this chapter.

b. **Land Uses**

The land uses for the site are designated as agricultural use.

c. **Environmental Features**

Extensive low-quality wetlands are present on the site. Known presence of listed species nearby, e.g. wood storks, will require further investigation.

d. **Water Quantities**

As previously discussed, needed water quantities for fossil generation would be up to 150 gallons per minute (gpm) for process water and up to 7.5 million gallons per day (mgd) per unit for cooling water (assuming a cooling tower is utilized).

e. **Supply Sources**

Groundwater from the shallow aquifer or a local source of reclaimed (reuse) water has been identified as potential water sources. The Floridan Aquifer has also been identified as a potential cooling water source. FPL will also consider the potential for alternative water development options at this site.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints: external limitations and internal limitations. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance that is available to the FPL system as well as the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In the loss of load probability (LOLP) portion of its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new units that minimize adverse impacts to the flow of electricity within FPL's system. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations and by evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system. Both of these site- and system-related transmission costs are developed for each different unit/unit location option or groups of options. In addition, transfer limits for capacity and energy that can be imported into the

Southeastern (Miami-Dade and Broward counties) region of FPL's system are also developed for use in FPL's production costing analyses. (A further discussion of the Southeastern Florida region, and the need to maintain a regional balance between generation and transmission contributions, is found in Chapter III.)

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's planned transmission facilities to interconnect and integrate FPL's resource plans and those that must be certified under the Transmission Line Siting Act are presented in Chapter III.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.[6]

The load forecast that is presented in FPL's 2011 Site Plan was developed in February 2011. FPL has not performed sensitivity analyses on forecasts that differ from this recently developed load forecast.

[6] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis (i.e., when only new generating options are considered), the lowest electric rate basis approach and the lowest system revenue requirements basis approach, yield identical results in terms of which resource options are more economic. In such cases FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its fuel price forecasts are discussed in Chapter III of this document. FPL used three fuel cost, and three environmental compliance cost, forecasts in its 2010 nuclear cost recovery filings. FPL utilized one fuel cost forecast, and one environmental compliance cost forecast in its DSM Plan analysis work in 2010 and early 2011.

The high and low fuel cost forecasts are derived from a calculation of the historical volatility of the 12-month forward price for one year ahead. From this range of volatility, a reasonable value from the high end of the range is applied to the medium cost fuel cost forecast to develop a high cost fuel cost forecast. Similarly, a reasonable value from the low end of the range is applied to the medium cost fuel cost forecast to develop a low cost fuel cost forecast.

The use of varying high and low fuel cost forecasts did not affect the generation expansion plan used in any of FPL's 2010 planning efforts.

The resource plan presented in this Site Plan is based, in part, on those prior analyses. For that reason, this resource plan, with the recently developed February 2011 load forecast, has not been further tested for different fuel cost forecasts.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item # 3, FPL used up to three fuel cost forecasts in its 2010 resource planning analyses. While these forecasts did not represent a constant cost differential between oil/gas and coal, a variety of fuel cost differentials were represented in these forecasts.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 in Chapter I and Schedule 8 in Chapter III present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years. However, as discussed briefly in the Executive Summary, and again in more detail in Chapter III, FPL is now projecting that it will begin to perform planned maintenance of its fossil-fueled generating units during the peak months of January and August. Please refer to Chapter III for this discussion.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options in its resource planning work. A summary of this information for the new capacity options FPL currently projects to add over the planning horizon is presented on the Schedule 9 forms in Chapter III.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

In its 2010 resource planning work, FPL used several sets of financial assumptions. Two sets of these assumptions were initially used in FPL's 2010 resource planning work. The first set consisted of: (i) a capital structure of 44.8% debt and 55.2% equity; (ii) a 6.48% cost of debt; (iii) a 10.0% return on equity; and (iv) an after-tax discount rate of 7.30%. A second set of data with the same debt-to-equity ratio and cost of debt, but with an 11.75% return on equity and an after-tax discount rate of 8.27%, was also used.

Later in 2010, FPL adjusted its financial assumptions and used new two sets of financial assumptions. The first set consisted of: i) a capital structure of 40.88% debt and 59.12% equity; (ii) a 6.51% cost of debt; (iii) a 10.0% return on equity; and (iv) an after-tax discount rate of 7.55%. Again, a second set of data with the same debt-to-equity ratio and cost of debt, but with an 11.75% return on equity and an after-tax discount rate of 8.58%, was used.

Going forward in 2011, FPL has again adjusted its financial assumptions. The base case financial assumptions are currently projected to be: i) a capital structure of 40.88% debt and 59.12% equity; (ii) a 5.50% cost of debt; (iii) a 10.0% return on equity; and (iv) an after-tax discount rate of 7.29%. For certain analyses, such as sensitivity analyses for FPL's two nuclear projects, a second set of financial assumptions may be used. This second set of data is currently projected to consist of the same debt-to-equity ratio and cost of debt as just described, but with an 11.75% return on equity and an after-tax discount rate of 8.33%.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the objective generally being to minimize FPL's projected levelized system average electric rate (i.e., a Rate Impact Measure or RIM approach). As discussed in response to Discussion Item # 2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective are identical when DSM levels are unchanged between competing resource plans. Therefore, in planning work in which DSM levels were unchanged, the equivalent cumulative present value of revenue requirements perspective was utilized.

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL currently uses two system reliability criteria in its resource planning work that addresses generation, purchase, and DSM options. One of these is a minimum 20% Summer and Winter reserve margin. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document. As discussed briefly in the Executive Summary, and in more detail in Chapter III, FPL will be examining the extent to which its system reserves are projected to be dependent upon DSM resources and generation resources in its 2011 resource planning work. The results of this examination could require in a change to FPL's reliability criteria.

In regard to transmission reliability analysis work, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the Reliability Standards established by the North American Electric Reliability Council (NERC). The *NERC Reliability Standards* are available on the internet site (http://www.nerc.com/).

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Facility Rating Methodology* document that are also available on the internet under the FPL OATT Documents directory at https://www.oatioasis.com/FPL/index.html.

Generally, FPL limits its transmission facilities to 100% of the applicable thermal rating. The normal and contingency voltage criteria for FPL stations are provided below:

Normal/Contingency

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95/0.95	1.05/1.07
230	0.95/0.95	1.06/1.07
500	0.95/0.95	1.07/1.09
Turkey Point (*)	1.01/1.01	1.06/1.06
St. Lucie (*)	1.00/1.00	1.06/1.06

(*) Voltage range criteria for FPL's Nuclear Power Plants

There may be isolated cases for which FPL may have determined that it is acceptable to deviate from the general criteria stated above. There are several factors that could influence these criteria, such as the overall number of potential customers that may be impacted, the probability of an outage actually occurring, or transmission system performance, as well as others.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM programs on demand and energy consumption is revised periodically. Engineering models, calibrated with current field-metered data, are updated at regular intervals. Participation trends are tracked for all of the FPL DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

The Executive Summary and Chapter III provide a discussion of a variety of system concerns/issues that influence FPL's resource planning process. Please see those chapters for a discussion of those concerns/issues.

In addition to these system concerns/issues, there are other strategic factors FPL typically considers when choosing between resource options. These include the following: (1) technology risk; (2) environmental risk, and (3) site feasibility. The consideration of these factors may include both economic and non-economic aspects.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology, which has not achieved general commercial acceptance, has a higher risk than a technology in wide use and, therefore, assuming all else equal, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts on the FPL system, including environmental compliance costs. Technologies regarded as more acceptable from an environmental perspective for a plan are those which minimize environmental impacts for the FPL system as a whole through highly efficient fuel use and/or state of the art controls.

Site feasibility assesses a wide range of economic, regulatory, and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed in prior FPL Site Plans, elements of FPL's recent and future capacity additions include the construction of new generating capacity at the West County Energy Center (WCEC) site, WCEC Unit 3. This generation construction project was selected after evaluating competing bids received in response to Requests for Proposals (RFP) issued by FPL. The FPSC subsequently approved FPL's decision to construct this new combined cycle (CC) unit in a Determination of Need docket.

In regard to the Modernization projects at FPL's existing Cape Canaveral and Riviera plants, these projects were also evaluated using the competing bids received in response to the RFP issued for WCEC Unit 3. In addition, bids from competing vendors were also evaluated for FPL's recent solar thermal and PV projects.

The nuclear capacity additions, both the nuclear uprates and the new nuclear units, do not lend themselves to an RFP approach involving bids from third parties who would build new nuclear generation capacity. In addition, nuclear capacity additions are exempted from the Commission's Bid Rule by section 403.519 (4) (c). For these nuclear projects, FPL's procurement activities were conducted to ensure the best combination of quality and cost for the delivered products.

Construction capacity addition decisions for non-nuclear generation for the years 2016 through 2020 presented in this document are expected to be conducted in a manner consistent with the Commission's Bid Rule.

Identification of self-build options, beyond those units already approved by the FPSC and Governor and Siting Board or units for which FPL may be then seeking approval, in future FPL Site Plans will not be an indication that FPL has pre-judged any capacity solicitation it may conduct. The identification of future generating units is required of FPL in its Site Plan filings and represents those alternatives that appear to be FPL's best, most cost-effective self-build options at the time. FPL reserves the right to refine its planning analyses and to identify other self-build options. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an RFP is issued for Supply options, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

(1) FPL has identified the need for a new 230kV transmission line that required certification under the Transmission Line Siting Act which was issued in April 2006. The new line is to be completed in two phases connecting FPL's St. Johns Substation to FPL's Pringle Substation (also shown on Table III.E.1 in Chapter III). Phase 1 was completed in May 2009 and consisted of a new line connecting Pringle to a new Pellicer Substation. Phase 2 is planned to connect St. Johns to Pellicer and is scheduled to be completed by December 2016. The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

(2) FPL has identified the need for a new 230kV transmission line (by December 2015) that required certification under the Transmission Line Siting Act which was issued on November 2008. The new line will connect FPL's Manatee Substation to FPL's proposed Bob White Substation (also shown on Table III.E.1 in Chapter III). The construction of this line, scheduled to be completed in 2015, is necessary to serve existing and future customers in the Manatee and Sarasota areas in a reliable and effective manner.

Re: Docket No. 110000; Corrections to FPL's 2011 Ten Year Power Plant Site Plan

Dear Ms. Cole:

Please find enclosed an original and 25 copies of four replacement pages for FPL's 2011 Ten Year Power Plant Site Plan, originally filed on April 1, 2011, reflecting corrected information.

Specifically, pages 45, 46, 98, and 116 are being replaced. Corrections are included in red, bold font.

Please contact me if you have any questions regarding this filing.

Sincerely,

for Lynne A. Adams
Jessica Cano

Enclosures

Schedule 3.1
History and Forecast of Summer Peak Demand (MW)
(Historical)

(1) Year	(2) Total	(3) Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management	(7) Residential Conservation	(8) C/I Load Management	(9) C/I Conservation	(10) Net Firm Demand
2001	18,754	169	18,585	0	842	697	489	481	17,423
2002	19,219	261	18,958	0	879	754	489	517	17,851
2003	19,668	253	19,415	0	892	798	577	554	18,200
2004	20,545	258	20,287	0	894	846	588	577	19,063
2005	22,361	264	22,097	0	902	895	600	611	20,858
2006	21,819	256	21,563	0	928	948	635	640	20,256
2007	21,962	261	21,701	0	952	982	716	683	20,295
2008	21,060	181	20,879	0	966	1042	760	706	19,334
2009	22,351	249	22,102	0	981	1097	811	732	20,558
2010	22,256	419	21,837	0	990	1147	815	749	18,555

Historical Values (2001 - 2010):

Col. (2) - Col. (4) are actual values for historical Summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) represent actual DSM capabilities starting from January 1988 and are annual (12-month) values except for 2010 values which are August values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC), CILC, and Commercial /Industrial Demand Reduction (CDR). Historical Residential Load Management MWs reflect the effect of new Measurement and Verification kw/participant factors.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" as if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col.(2) - Col.(6) - Col.(8).

Schedule 3.1
History and Forecast of Summer Peak Demand (MW)
(Projected)

(1) August of Year	(2) Total	(3) Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management	(7) Residential Conservation	(8) C/I Load Management	(9) C/I Conservation	(10) Net Firm Demand
2011	21,679	383	21,295	0	1,005	79	858	39	19,697
2012	21,853	385	21,468	0	1,017	154	878	93	19,712
2013	22,155	343	21,812	0	1,023	244	896	154	19,837
2014	23,452	1,129	22,322	0	1,041	343	934	216	20,917
2015	24,172	1,136	23,037	0	1,044	442	952	272	21,462
2016	24,605	1,143	23,463	0	1,047	536	971	318	21,734
2017	25,025	1,150	23,875	0	1,050	625	989	353	22,008
2018	25,266	1,157	24,109	0	1,053	711	1,007	378	22,117
2019	25,690	1,165	24,526	0	1,056	792	1,026	397	22,419
2020	26,193	1,172	25,022	0	1,060	837	1,042	412	22,823

Projected Values (2011 - 2020):

Col. (2) - Col. (4) represent FPL's forecasted peak w/o incremental conservation, cumulative load management, or incremental load management.

Col. (5) - Col. (9) represent cumulative load management, and incremental conservation and load management. All values are projected August values. The 2011 values are based on IRP projections after the 2010 Summer peak and FPL's new DSM Goals for 2011. The projections for 2012 through 2020 are based on FPL's DSM Goals. Res. Load Management and C/I Load Management include MW values of load management capability from Lee County that can be initiated at FPL's request.

Col. (8) represents FPL's Business On Call, CDR, CILC, and Curtailable programs/rates.

Col. (10) represents a 'Net Firm Demand' which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.2
History and Forecast of Winter Peak Demand:Base Case
(Historical)

(1) The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All MW additions/changes occuring later in the year will be picked up for reporting/planning purposes in the following year.

(2) The nuclear uprates will be performed during the extended outages for each unit.

(12)	*Total:*	*25,824.0*	*100.0%*	*26,983.0*	*100.0%*	*114,373*	*100.0%*

Note:
(1) FPL Existing Units Total values on row (7), columns (2) and (4), match the System Firm Generating Capacity values found on Schedule 1 for Summer and Winter.
(2) Net Energy for Load GWh values on row (12), column (6), matches Schedule 6.1 value for 2010.

Schedule 11.2

Existing NON-FIRM Self-Service Renewable Generation Facilities
Actuals for the Year 2010

(1)	(2)	(3)	(4)	(5)	(6) = 3+4-5
Type of Facility	Installed Capacity DC (MW)	Renewable Projected Annual Output (MWh)	Annual Energy Purchased from FPL (MWh)	Annual Energy Sold to FPL (MWh)	Projected Annual Energy Used by Customers (GWh)
Customer-Owned PV (0 kW to 10 kW)	4.6	5,214.7	53,476.4	146.5	58.5
Customer-Owned PV (> 10 kW to 100 kW)	1.6	1,775.4	17,858.8	158.2	19.5
Customer-Owned PV (> 100 kW to 2 MW)	2.9	3,708.4	118,662.7	177.6	118,666.2
Total:	9.2	10,698.5	189,998.0	482.2	118,744.2

Notes:

(1) There were approximately 1,064 customer-owned renewable generation facilities interconnected with FPL on December 31, 2010.
(2) The Installed Capacity value is the sum of the nameplate ratings (DC MW) for all of the customer-owned renewable generation facilities connected as of Dec. 31,2010.
(3) The Projected Annual Output value is based on NREL's PV Watts 1 program and the Installed Capacity value in column (2), adjusted for the date when each facility was installed and assuming each facility operated as planned.
(4) The Annual Energy Purchased from FPL is an actual value from FPL's metered data for 2010.
(5) The Annual Energy Sold to FPL is an actual value from FPL's metered data for 2010.
(6) The Projected Annual Energy Used by Customers is a projected value that equals:
(Renewable Projected Annual output + Annual Energy Purchased from FPL) minus the Annual Energy Sold to FPL.

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan. This plan should include an estimate of the utility's future electric power generating needs, a projection of how these estimated generating needs might be met, and disclosure of information pertaining to the utility's preferred and potential power plant sites. The information contained in this Site Plan is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (F.A.C.).

This Ten Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2011 and that were on-going in the first Quarter of 2012. The forecasted information presented in this plan addresses the years 2012 through 2021.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information and all of this information is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings, at the appropriate time.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, based on FPL's IRP work in 2011 and

early 2012.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as Preferred and Potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional information that is included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2012 Ten Year Power Plant Site Plan (Site Plan) presents FPL's current plans to augment and enhance its electric generation capability (owned or purchased) as part of its efforts to meet its projected incremental resource needs for the 2012 - 2021 time period. By design, the primary focus of this document is on supply side additions; i.e., electric generation capability and the sites for these additions. The supply side additions discussed in this document are resources projected to be needed after accounting for FPL's demand side management (DSM) efforts and the significant energy efficiency contributions from the current federal appliance and lighting efficiency standards. The projected impacts of the federal appliance and lighting efficiency standards are accounted for in FPL's load forecast which is discussed in Chapter II. The projected impacts of FPL's DSM efforts are addressed as projected reductions to the forecasted load. FPL's DSM programs are presented in Chapter III.

The resource plan that is presented in FPL's 2012 Site Plan contains a number of key similarities to the resource plan presented in FPL's 2011 Site Plan. On the other hand, there are specific factors that result in changes in FPL's current resource plan compared to the resource plan presented in FPL's 2011 Site Plan. There are also other factors that will continue to influence FPL's on-going resource planning work. A brief discussion of these similarities, changes, and factors is provided below. Additional information regarding many of these topics is presented in Chapter III.

I. Similarities to the Resource Plan Previously Presented in FPL's 2011 Site Plan:

There are four key similarities in the current resource plan presented in this document compared to the resource plan presented in the 2011 Site Plan.

Similarity # 1: Generating capacity at FPL's four existing nuclear generation units will continue to increase in the 2012 – 2013 time frame.

FPL will be adding approximately 490 MW of increased generating capacity from "uprates" at its existing Turkey Point and St. Lucie nuclear power plants. 31 MW of this increased capacity has already come in-service at St. Lucie Unit 2 and is already benefiting FPL's customers. The capacity uprates at 3 of the 4 nuclear units are currently projected to be completed by the end of 2012 and the uprate at the 4th unit is projected to be completed by March 2013. The need for these nuclear capacity uprates was approved by the FPSC in January 2008 in Order No. PSC-08-0021-FOF-EI. The Final Order for the Site Certification was issued in September 2008 for the

St. Lucie uprates in Order No. DEP 08-0942 and in October 2008 for the Turkey Point uprates in Order No. DEP 08-1141. [1]

Similarity # 2: FPL continues to pursue licenses, permits, and approvals that would be necessary for future construction and operation of two new nuclear generating units at its Turkey Point site.

FPL is continuing its work to obtain all of the licenses, permits, and approvals that would be necessary to construct and operate two new nuclear units at its Turkey Point site in the future. These licenses, permits, and approvals will provide FPL with the opportunity to construct these nuclear units at Turkey Point for a time expected to be up to 20 years from the time the licenses and permits are granted, and then to operate the units for at least 40 years thereafter. The earliest practical deployment dates for the two new units continue to be beyond the 10-year reporting period for this Site Plan. Therefore, these additions are not shown in this document.

Similarity # 3: A number of existing generating units have been placed on Inactive Reserve.

In 2009, FPL began to take a number of its existing generating units out of active service and has placed them on Inactive Reserve status. The specific generating units that have been placed on Inactive Reserve status are discussed in Chapter III of this document. However, there are changes in regard to FPL's current plans for these units that are discussed later in this Executive Summary and in more detail in Chapter III.

Similarity # 4: The modernizations of FPL's existing Cape Canaveral and Riviera plant sites are underway and are projected to be completed on time in 2013 and 2014, respectively.

FPL's 2011 Site Plan projected that the modernizations of these two existing sites would be completed in 2013 (Cape Canaveral) and 2014 (Riviera). FPL received need determination approval from the FPSC for both of these modernizations in September 2008 in Order No. PSC-08-0591-FOF-EI. Site Certification was received for Cape Canaveral in October 2009 in Order No. DEP 09-1015. Site Certification was received for Riviera in November 2009 in Order No. DEP O9-1245. The work to complete these modernizations is underway, on budget and these modernizations are again reflected in this Site Plan with no changes to the projected completion dates.

[1] The nuclear uprate project outage schedules for 2012 and 2013 are still being developed at the time the 2012 Site Plan is being finalized. The project schedule dates presented in this Site Plan document are the best available information available at this time. However, this schedule information is subject to change.

II. Factors That Are Driving Changes in FPL's Resource Plan:

There are two primary factors that are driving changes in FPL's 2012 resource plan compared to the resource plan presented in FPL's 2011 Site Plan. These changes are summarized below.

Factor # 1: It will not be necessary to schedule planned maintenance outages for FPL's fleet of fossil-fueled generating units during all Summer and Winter peak load months.

In FPL's 2011 Site Plan, it was projected that scheduled maintenance for FPL's generating units would need to be extended into all Summer and Winter peak load months. After further analysis, FPL concluded that it would not be necessary to schedule maintenance during all peak load months. (However, FPL will maintain the practice of using available capacity year-round for scheduling maintenance of its fossil-fueled units as opportunities arise.)

Factor # 2: Changes in the load forecast, generating unit capabilities, and power purchase capabilities have combined to result in a net lowering of FPL's projected resource needs through 2021.

The combined effect of several factors has led to a lowering of FPL's projected resource needs. In addition to the aforementioned removal of scheduled maintenance during peak load months, FPL is also projecting a load forecast that is slightly lower than the forecast used in the 2011 Site Plan. Also, several FPL units are now projected to increase their capabilities during the 2012-2021 time frame. These increases include additional incremental generation from the modernization at the Port Everglades site, greater than previously projected output from the nuclear capacity uprates project, and upgrades to the combustion turbines at several of FPL's combined cycle plant sites. The effect of these projects is only slightly offset by a decrease in the amount of a purchased power agreement (PPA) with Palm Beach SWA. However, the combined net effects result in an overall decrease in FPL's projected resource needs.

III. Resulting Changes in FPL's Resource Plan Compared to the Resource Plan Previously Presented in FPL's 2011 Site Plan:

The combined effect of the factors discussed above contributed to three significant changes in FPL's resource plan presented in this document compared to the resource plan previously presented in FPL's 2011 Site Plan. These changes are presented below and are discussed in more detail in Chapter III.

Change # 1: FPL's next resource need will be met by the modernization of FPL's Port Everglades site.

In its 2011 Site Plan, FPL projected, for planning purposes, to meet its next resource need with a Greenfield combined cycle (CC) unit that would come in-service in 2016. However, FPL discussed in its 2011 Site Plan that FPL was examining a variety of options with which to meet this need including a modernization of the Port Everglades site. Subsequent analyses determined that a modernization of this site was the most economic and best option for FPL's customers. FPL filed for a need determination for the modernization on November 21, 2011. The FPSC voted on March 27, 2012, to approve the modernization of Port Everglades with a 2016 in-service date. (As a result, Port Everglades' existing generating units 1 – 4, currently on Inactive Reserve status, will eventually be removed as part of the modernization process.)

Change # 2: Three generating units are being retired and two other generating units have been/will be switched to operate as synchronous condensers.

Sanford Unit 3, Cutler Unit 5, and Cutler Unit 6 are currently on Inactive Reserve status and will be retired in the fourth quarter of 2012. In addition, Turkey Point Unit 2 has been converted to operate in synchronous condenser mode to provide voltage support for the transmission system in Southeastern Florida. FPL also projects that Turkey Point Unit 1 will be similarly converted to run in synchronous condenser mode starting in 2016.

Change # 3: FPL's next resource need is now projected to be in 2021.

FPL's 2011 Site Plan showed a resource need in 2020 that was originally projected to be met with a Greenfield CC unit. This resource need has moved back one year from 2020 to 2021. FPL has made no decision regarding how this need will be met. For planning purposes, FPL is currently assuming that this 2021 resource need will be met by a PPA in 2021.

IV. Additional Factors Influencing FPL's Resource Planning Work:

In addition to the two factors previously mentioned (no necessity to schedule or execute planned maintenance in all peak load months and a projection of lower resource needs through the end of the 10-year reporting time frame of this document) that are driving changes in FPL's resource plans, there are additional factors that also influence FPL's resource planning work. Among these other additional factors are two that FPL typically refers to as on-going system concerns that FPL has considered in its resource planning work for a number of years. These two on-going system concerns are: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida, particularly in Miami-Dade and Broward Counties.

A third factor that could affect FPL's resource planning is the possibility of the establishment of a Florida standard for renewable energy or clean energy. A Renewable Portfolio Standard (RPS) proposal was prepared by the FPSC, and then sent to the Florida Legislature for consideration, with a possible change to a Clean Portfolio Standard (CPS), during the 2009 legislative session. However, no RPS or CPS legislation has been enacted in subsequent legislative sessions. Furthermore, during the 2012 legislative session the legislature deleted a now obsolete directive to the FPSC that had instructed them to adopt RPS rules. RPS or CPS legislation, or other legislative initiatives regarding renewable or clean energy contributions, may still occur in the future. If such legislation is enacted in later years, FPL would then determine what steps need to be taken to address the legislation. Such steps would then be discussed in FPL's Site Plan in the year following the enactment of such legislation.

A fourth factor that will affect FPL's resource planning is the issue of how best to reliably obtain additional natural gas for FPL's system which is needed due to growing electrical load. This need for additional natural gas is minimized, but only in part, by the addition of highly fuel-efficient natural gas-fired generating units with the modernizations of the Cape Canaveral, Riviera, and Port Everglades plant sites.

A fifth factor or issue that will affect FPL's resource planning is the extent to which FPL's reserves are projected to become increasingly dependent upon DSM resources as opposed to generation resources. This projected imbalance in future reserves is becoming more pronounced, in part, because of the high level of DSM currently required to be implemented while FPL's projected resource needs have decreased (as previously mentioned).

Each of these factors will continue to be examined in FPL's on-going resource planning work during the rest of 2012 and in future years.

Table ES-1 presents a current projection of major changes to specific generating units and firm capacity purchases for 2012 – 2021 in terms of Summer MW. Table ES-2 then expands upon the information presented in Table ES-1 by adding projections of Winter MW impacts, Summer reserve margins, Winter reserve margins, etc. (Although neither table specifically identifies the impacts of projected DSM additions on FPL's resource needs and resource plan, FPL's projected DSM additions have been fully accounted for in the resource plan presented in this Site Plan.)

Table ES-1: Projected Capacity & Firm Purchase Power Changes

*Year **	*Projected Capacity & Firm Purchase Power Changes*	*Summer MW*	*Date*
2012	Inactive Reserve Unit (PE Units 3 & 4) - active service	761	January-12
	DeSoto 1 Short Term Purchase	150	January-12

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.
(2) Winter values are forecasted values for January of the year shown.
(3) Summer values are forecasted values for August of the year shown.
(4) These are firm capacity and energy contracts with QF, utilities, and other entities. See Table I.B.1 and Table I.B.2 for more details.
(5) All new unit additions are scheduled to be in-service in June of the year shown. All additions assumed to start in June are included in the Summer reserve margin calculation starting in that year and in the Winter reserve margin calculation starting with the next year.
(6) Outages for uprate work.
(7) Outages for ESP work.
(8) A number of existing FPL power plants have been removed from service and placed on Inactive Reserve status. See Chapter III for a discussion of the units on Inactive Reserves.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8.8 million people. FPL served an average of 4,547,051 customer accounts in thirty-five counties during 2011. These customers were served by a variety of resources including: FPL-owned fossil-fueled, renewable, and nuclear generating units, non-utility owned generation, demand side management (DSM), and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at seventeen generating sites distributed geographically around its service territory including one site in Georgia (partial FPL ownership of one unit) and one site in Jacksonville, Florida (partial FPL ownership of two units). The current electrical generating facilities consist of four nuclear units, three coal units, fifteen combined cycle (CC) units, twelve fossil steam units, forty-eight combustion gas turbines, one simple cycle combustion turbine, and two photovoltaic facilities[2]. The locations of these eighty-five generating units are shown on Figure I.A.1 and in Table I.A.1. Table I.A.2 provides a "break down" of the capacity provided by the combustion turbine (CT) and steam turbine (ST) components of FPL's existing CC units.

FPL's bulk transmission system is comprised of 6,721 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 587 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

[2] FPL also has one 75 MW solar thermal facility at its Martin plant site. This facility does not generate electricity as the other units mentioned above do. Instead, it produces steam that reduces the use of fossil fuel to produce steam for electricity generation.

FPL Generating Resources by Location

Location/ Map Key	Plant Name	Number of Units	Summer MW
A	Turkey Point [1/]	4	2,930
B	St. Lucie [2/]	2	1,584

1/ Turkey Point Unit 2 is now a synchronous condenser
2/ Represents FPL's ownership share: St Lucie nuclear: 100% Unit 1, 85% Unit 2: St. Johns River: 20% of two units
3/ Cutler Units 5 &6, Port Everglades Units 1- 4 and Sanford Unit 3 are on Inactive Reserve status
Their capacity values are presented on the MW-by-unit line only to assist in comparisons back to previous Site Plans. However, the capacity from the Inactive Reserve units has been removed from the "Total System Generation without Inactive Reserves row at the end of the table.
4/ Will be site of new Modernization Plants
5/ The 25 MW of PV at DeSoto and the 10 MW of PV at Space Coast are considered as non-firm generating capacity and the capacity from these units has been removed from the "System Firm Generation" row at the end of the table
6/ The Scherer unit is located in Georgia and is not shown on this map

I.B Firm Capacity Power Purchases

Purchases from Qualifying Facilities (QF):

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with five qualifying facilities; i.e., cogeneration/small power production facilities, to purchase firm capacity and energy as shown in Table I.A.3, Table I.B.1, and Table I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Purchases from Utilities:

FPL has a Unit Power Sales (UPS) contract to purchase 928 MW from the Southern Company (Southern) through the end of December 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 375 MW (Summer) and 383 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. However, due to Internal Revenue Service (IRS) regulations, the total amount of energy that FPL may receive from this purchase is limited. FPL currently assumes, for planning purposes, that this limit will be reached in the Spring of 2017. Once this limit is reached, FPL will be unable to receive firm capacity and energy from these purchases. (However, FPL will continue to receive firm capacity and energy from its ownership portion of the SJRPP units.)

FPL has an additional one-year contract with TECO for 125 MW of firm capacity through December 2012.

These purchases are shown in Table I.A.3, Table I.B.1, and Table I.B.2. FPL also has ownership interest in the SJRPP units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.

Other Purchases:

FPL has three other short-term firm capacity purchase contracts with non-QF, non-utility suppliers. One of these purchase contracts runs through May 2012 and the other two run through December 2012. Table I.B.1 and I.B.2 present the Summer and Winter MW, respectively, resulting from these contracts under the category heading of Other Purchases.

I.C Non-Firm (As Available) Energy Purchases

FPL purchases non-firm (as-available) energy from several cogeneration and small power production facilities. Table I.C.1 shows the amount of energy purchased in 2011 from these facilities.

Table I.C.1: As-Available Energy Purchases From Non-Utility Generators in 2011

Project	County	Fuel	In-Service Date	Energy (MWH) Delivered to FPL in 2011

I.D. Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include a number of conservation/energy efficiency and load management initiatives. FPL's DSM efforts through 2011 have resulted in a cumulative Summer peak reduction of approximately 4,513 MW at the generator and an estimated cumulative energy saving of approximately 59,890 Gigawatt-hour (GWh) at the generator. After accounting for reserve margin requirements, FPL's DSM efforts through 2011 have eliminated the need to construct the equivalent of more than 13 new 400 MW generating units. DSM is discussed further in Chapter III.

1/ These ratings are peak capability.

2/ The Cape Canaveral modernization project has resulted in the removal of the two steam units previously at the Canaveral site to clear the site for the introduction of a new combined cycle generating unit. This new unit is projected to go into service in June 2013.

3/ Cutler Units 5 & 6 are on Inactive Reserve status. Their capacity values are presented on the MW-by-unit line only to assist in comparisons back to previous Site Plans. However, the capacity from the Inactive Reserve units has been removed from the "Total System Generation without Inactive Reserves as of December 31, 2011" row at the end of the table. Cutler Units 5 & 6 will be retired by the end of 2012.

4/ The capacity shown for the PV facility at DeSoto is considered as non-firm generating capacity and the capacity from these units has been removed from the "System Firm Generating Capacity as of December 31, 2011" row at the end of the table.

Total System Generating Capacity as of December 31, 2011 [6/] =												25,323	24,068
Total System Generation without Inactive Reserves as of December 31, 2011 [7/] =												23,783	22,538
System Firm Generating Capacity as of December 31, 2011 [8/] =												23,748	22,503

1/ These ratings are peak capability.

2 The capacity shown for the PV facility at Space Coast is considered as non-firm generating capacity due to the intermittent nature of the solar resource.

3/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Units 1 and 2, excluding the Jacksonville Electric Authority (JEA) share of 80%.

4/ Total capability of each unit is 853/839 MW. FPL's ownership share of St. Lucie Units 1 and 2 is 100%(853/839) and 85% (714/726), respectively, as shown above. FPL's share of the deliverable capacity from each unit is approx. 92.5% and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit.

5/ This generating unit is currently serving as a synchronous condenser.

6/ The Total System Generating Cpacity value shown includes FPL-owned firm and non-firm generating capacity

7/ The Total System Generation without the Inactive Reserves Units (Cutler Units 5 & 6, Port Everglades Units 1- 4, Sanford Unit 3).

8/ The System Firm Generating Capacity value shown includes only firm generating capacity

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

II. A. Overview of the Load Forecasting Process

Long-term forecasts of sales, net energy for load (NEL), and peak loads are typically developed on an annual basis for resource planning work at FPL. New long-term forecasts were developed by FPL in late 2011 that replaced the previous long-term load forecasts that were used by FPL during 2011 in much of its resource planning work and which were presented in FPL's 2011 Site Plan. These new load forecasts are utilized throughout FPL's 2012 Site Plan. These forecasts are a key input to the models used to develop FPL's integrated resource plan.

The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads. Consistent with past forecasts, the primary drivers to develop these forecasts include economic conditions and weather.

The projections for the national and Florida economies are obtained from the consulting firm IHS Global Insight. Population projections are obtained from the Florida Legislature's Office of Economic and Demographic Research (EDR). These projections are developed, in conjunction with the Bureau of Economic and Business Research (BEBR) of the University of Florida. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects FPL's energy sales and peak demand. Three sets of weather variables are developed and used in FPL's forecasting models:

1. Cooling and heating degree-hours based on 72° F, winter heating degree-days based on 66° F, and heating degree-days based on 45° F are used to forecast energy sales.
2. The maximum temperature on the peak day, along with the build-up of cooling degree-hours prior to the peak, are used to forecast Summer peaks.
3. The minimum temperature on the peak day, along with the build-up of heating degree-hours based on 66° F on the day prior to the peak, are used to forecast Winter peaks.

The cooling degree-hours and winter heating degree-days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. Heating degree-days based on 45° F are used to capture heating load resulting from sustained periods of unusually cold weather not fully captured by heating degree-days based on 66° F. A composite hourly temperature profile is derived using hourly temperatures across FPL's service territory. Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained. In developing the composite hourly profile, these regional temperatures are weighted by regional energy sales. The resulting composite temperature is used to derive projected cooling degree-hours and heating degree-days. Similarly, composite temperature and hourly profiles of temperatures are used for the Summer and Winter peak models.

II. B. Comparison of FPL's Current and Previous Load Forecasts

FPL's current load forecast is somewhat lower than the load forecast presented in its 2011 Site Plan. There are three primary factors that are driving the current load forecast: projected population growth, a projection of gradual recovery following the economic recession in Florida, and energy efficiency standards. The net impact of these three factors is that the current load forecast is lower than the 2011 Site Plan forecast.

The customer forecast is based on recent population projections. Population projections are derived from the EDR's August 2011 Demographic Estimating Conference. This forecast indicates generally lower population levels than previously forecasted although long-term rates of population growth are comparable. Net migration into Florida fell to a record low in 2009 during the height of the recession. Florida has since experienced a small rebound in net migration, but population growth rates have remained well below their historical averages. The population growth rate projected for 2012 reflects a continuation of the low rates of population growth Florida has experienced since the start of the recession. Progressively higher rates of population growth are projected until 2016 when population growth approaches the level historically experienced in Florida. Consistent with prior population projection from EDR, the rate of population growth is expected to gradually stabilize after 2016.

FPL's customer base is expected to mirror the state's projected rates of population growth. As population growth recovers, modestly higher customer growth is projected thru 2016, followed by relatively stable growth thereafter. By 2019, the total number of customer accounts (customers) is expected to exceed five million. Between 2012 and 2021, the total number of customers projected in the current load forecast is about 1%

below the levels projected in FPL's 2011 Site Plan, however the longer-term percentage growth rates are comparable.

After suffering for years under the lingering effects of the recent recession, the outlook on the Florida economy is now one of cautious optimism. By year-end 2011, Florida was adding jobs at an annual rate of more than 100,000; more than in any year since 2006. Although significant problems persist in the housing market, the outlook for Florida is for positive, if somewhat modest economic growth. Accordingly, IHS Global Insight is projecting a steady increase in employment and income growth through 2015 after which growth moderates.

Estimates of savings from energy efficiency standards are developed by ITRON, a leading expert in this area. Included in these estimates are savings from federal and state energy efficiency standards, including the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the savings occurring from the use of compact fluorescent bulbs.[3]

Consistent with the forecast presented in FPL's 2011 Site Plan, the total growth projected for the ten-year reporting period of this document is significant. The Summer peak is projected to increase to 25,960 MW by 2021, an increase of 4,341 MW over the 2011 actual Summer peak. Likewise, NEL is projected to reach 133,646 GWH in 2021, an increase of 21,192 GWH from the actual 2011 value.

II.C. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class and are adjusted to match the NEL forecast. The results of these sales forecasts for the years 2012 - 2021 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and NEL forecast are outlined below.

1. Residential Sales

Residential electric usage per customer is estimated by using an econometric model. Residential sales are a function of: cooling degree-hours, heating degree-hours,

[3] Note that in addition to the fact that these energy efficiency standards lower the forecasted load (as described in more detail later in this chapter), these standards also lower the efficiency potential that would otherwise be available through utility DSM programs.

lagged cooling degree-hours, lagged heating degree-hours, a proxy for energy prices, and Florida real per capita income weighted by the percent of the population employed. The impact of weather is captured by the cooling degree-hours, heating degree-hours, and the one month lag of these variables. The proxy for energy prices incorporates the impact of energy prices on electric consumption. As energy prices rise, less disposable income is available for all goods and services, electricity included. To capture economic conditions, the model includes a composite variable based on Florida real per capita income and the percent of the state's population that is employed. Because of the relatively large percentage of Florida's population that has been unemployed during the recession, real per capita income alone does not capture the full magnitude of the downturn. The composite variable more accurately reflects economic conditions. Residential energy sales are forecasted by multiplying the residential use per customer forecast by the number of residential customers forecasted.

2. Commercial Sales

The commercial sales forecast is also developed using an econometric model. Commercial sales are a function of the following variables: Florida real per capita income weighted by the percent of the population employed, cooling degree-hours, heating degree-hours, lagged cooling degree-hours, a variable designed to reflect the impact of empty homes, a dummy variable for the month of December and for the specific month of January 2007, and an autoregressive term. Cooling degree-hours, heating degree-hours, and the one month lag of cooling degree-hours are used to capture weather-sensitive load in the commercial sector.

3. Industrial Sales

The industrial class is comprised of three distinct groups: very small accounts (those with less than 20 kW of demand), medium accounts (those with 21 kW to 499 kW of demand), and large accounts (those with demands of 500 kW or higher). As such, the forecast is developed using a separate econometric model for each group of industrial customers. The small industrial sales model utilizes the following variables: Florida real disposable income, cooling degree-hours, heating degree-hours, a dummy variable for the specific month of February 2009, and an autoregressive term. The medium industrial sales model utilizes the following variables: cooling degree-hours, Florida real disposable income, a dummy variable for the specific month of February 2006, and two autoregressive terms. The large industrial sales model utilizes the following variables: Florida real per capita income, the Consumer Price

Index, the industrial real price of electricity (a 24-month moving average), and a dummy variable for the specific month of October 2004.

4. Railroad and Railways Sales and Street and Highway Sales

This class consists solely of Miami-Dade County's Metrorail system. The projections for railroad and railways sales are based on historical average use per customer which is multiplied by the forecasted number of customers. The number of customers is based on the planned addition of new Metrorail stations.

The forecast for street and highway sales is developed by using a trended use per customer, which is multiplied by the number of forecasted customers.

5. Other Public Authority Sales

This revenue class is closed to new customers. This class consists of sports fields and one government account. The forecast for this class is based on historical knowledge of its usage characteristics.

6. Total Sales to Ultimate Customer

Sales forecasts by revenue class are summed to produce a total sales forecast.

7. Sales for Resale

Sales for resale (wholesale) customers are composed of municipalities and/or electric co-operatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers. Currently there are five customers in this class: the Florida Keys Electric Cooperative; City of Key West; Metro-Dade County; Lee County Electric Cooperative; and Wauchula. In addition, FPL will begin making sales to Seminole Electric Cooperative in June 2014 under a long term agreement[4].

Beginning in May 2011, FPL began providing service to the Florida Keys Electric Cooperative under a long-term full requirements contract. Previously FPL was serving the Florida Keys under a partial requirements contract. The sales to Florida Keys Electric Cooperative are based on customer-supplied information and historical load factors.

[4] FPL is currently evaluating the possibility of serving the electrical loads of several entities (including Vero Beach and Lake Worth) at the time the 2012 Site Plan is being prepared. Because these possibilities are still being evaluated, the load forecast presented in this Site Plan does not include these potential loads.

FPL's sales to the City of Key West are expected to terminate in 2013. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor.

Metro-Dade County sells 60 MW to Progress Energy Florida. Line losses are billed to Metro-Dade under a wholesale contract. This contract expires in 2013.

Lee County has contracted with FPL for FPL to supply a portion of their load through 2013, then to begin serving their entire load beginning in 2014. This contract began in January 2010. Lee County provides a forecast of their sales by delivery point which is used to derive their sales forecast.

A new contract with Seminole Electric Cooperative is included in the forecast which includes delivery of 200 MW beginning in June 2014.

II.D. Net Energy for Load (NEL)

An econometric model is developed to produce a NEL per customer forecast. The inputs to the model include Florida real per capita income weighted by the percent of the population employed, and a proxy for energy prices. The model also includes three weather variables: Cooling degree-hours, winter heating degree-days, and heating degree-days based on 45° F. In addition, the model also includes variables for weather-sensitive energy efficiency standards and a variable designed to capture the impact of empty homes. Seasonal dummy variables are included for the months of February, April, June, September, and November and the specific months of March 2003, May 2004, and November 2005. There is also an autoregressive term in the model.

The weather-sensitive energy efficiency variable is included to capture the weather sensitive impacts of the 2005 National Energy Policy Act and the 2007 Energy Independence and Security Act. The estimated impact of this factor for the 2012 - 2021 time period is a reduction, on average, of 7,837 GWh per year. This reduction is inclusive of engineering estimates and any resulting behavioral changes. The increase in the number of empty homes resulting from the current housing slump has affected use per customer and is captured in a separate variable. The forecast was also adjusted for additional load estimated from hybrid vehicles, beginning in 2011, which resulted in an increase of approximately 1,010 GWh by the end of the ten-year reporting period. The forecast is also adjusted for projected incremental load resulting from FPL's economic development riders which will impact the forecast beginning in 2013, and result in an increase, on average, of 311 GWh per year between 2013 and 2021.

The NEL forecast is developed by multiplying the NEL per customer forecast by the total number of customers forecasted. Once the NEL forecast is obtained, total billed sales are computed using a historical ratio of sales to NEL. The sales by class forecasts previously discussed are then adjusted to match the total billed sales. The forecasted NEL values for 2012 - 2021 are presented in Schedule 3.3 that appears at the end of this chapter.

II.E. System Peak Forecasts

The rate of absolute growth in FPL system peak load has been a function of the size of the customer base, varying weather conditions, projected economic conditions, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient appliances and lighting. FPL developed the peak forecast models to capture these behavioral relationships. Impacts of the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the impact of compact fluorescent light bulbs are taken into account in developing the peak forecast. The estimated impact of these energy efficiency standards for the 2012 - 2021 time frame is a reduction of approximately 692 MW (Summer) and 521 MW (Winter) in 2012, and approximately 1,484 MW (Summer) and 1,360 MW (Winter) by 2021. The forecast was also adjusted for additional load estimated from hybrid vehicles which resulted in an increase of approximately 163 MW in the Summer and 58 MW in the Winter by the end of the ten-year reporting period.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2012 – 2021 are presented at the end of this chapter in Schedules 3.1 and 3.2, and in Chapter III in Schedules 7.1 through 7.4.

1. System Summer Peak

The Summer peak forecast is developed using an econometric model. The variables included in the model are the real price of electricity lagged one month, Florida real per capita income weighted by the percent of the population employed, cooling degree-hours in the day prior to the peak, the maximum temperature on the day of the peak, dummy variables for the years 1982, 1989, and 1990, and a variable for energy efficiency standards. The model is based on the Summer peak contribution per customer and is, therefore, multiplied by total customers, and adjusted to account for incremental loads resulting from hybrid vehicles, new wholesale contracts, and incremental load from FPL's economic development riders to derive FPL's system Summer peak.

2. System Winter Peak

Like the system Summer peak model, this model is also an econometric model. The model consists of two weather-related variables: the minimum temperature on the peak day and heating degree-hours for the prior day squared. The model also includes a dummy variable for winter peaks occurring on weekends and an autoregressive term. The forecasted results are adjusted for the impact of energy efficiency standards. The model is based on the Winter peak contribution per customer and is, therefore, multiplied by total customers, and adjusted to account for incremental loads resulting from hybrid vehicles, new wholesale contracts, and FPL's economic development riders, to derive FPL's system Winter peak.

3. Monthly Peak Forecasts

The forecasting process for monthly peaks consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to the appropriate seasonal peak.

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.F. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2012 - 2021 are produced using a System Load Forecasting "shaper" program. This model uses years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

II.G. Uncertainty

In order to address uncertainty in the forecasts of aggregate peak demand and NEL, FPL first evaluates the assumptions underlying the forecasts. FPL takes a series of steps in evaluating the input variables, including comparing projections from different sources, identifying outliers in the series, and assessing the series' consistency with past forecasts. As needed, FPL reviews additional factors which may affect the input variables.

Uncertainty is also addressed in the modeling process. Generally, econometric models are used to forecast the aggregate peak demand and NEL. During the modeling process, the relevant statistics (goodness of fit, F-statistic, P-values, mean absolute deviation (MAD), mean absolute percentage error (MAPE), etc.) are scrutinized to ensure that the models adequately explain historical variation. Once a forecast is developed, it is compared with past forecasts. Deviations from past forecasts are examined in light of changes in input assumptions to ensure that the drivers underlying the forecast are well understood. Finally, forecasts of aggregate peak demand and NEL are compared with their actual values as they become available. An ongoing process of variance analyses is performed. To the extent that the variance analysis identifies large unexplained deviations between the forecast and actual values, revisions to the econometric model may be considered.

The inherent uncertainty in load forecasting is addressed in different ways in regard to FPL's overall resource planning and operational planning work. In regard to FPL's resource planning work, FPL's utilization of a 20% reserve margin criterion (approved by the FPSC) is designed, in part, to maintain reliable electric service to FPL's customers in light of forecasting uncertainty. In regard to operational planning, an extreme weather load forecast for the projected Summer peak day is developed based on the historical distribution of temperatures on the day of the Summer peak. This produces a probability distribution of Summer peak outcomes with associated probabilities. Likewise, an extreme weather Winter peak forecast is developed based on the historical distribution of temperatures on the day of the Winter peak. Statistical analysis on the distribution of historical weather data is performed to evaluate and understand the impact of extreme weather on the peaks and on NEL, and the likelihood of experiencing extreme weather.

II.H. DSM

The effects of FPL's DSM energy efficiency programs implementation through August 2011 are assumed to be imbedded in the actual usage data for forecasting purposes. Any change in usage pattern, be it the impact of FPL's DSM energy efficiency efforts, price impact, or weather impact, is reflected in the actual observed load data. Therefore, energy efficiency impacts, whether market-driven or as a result of FPL's DSM programs, are assumed to be included in the historical usage data for peaks and NEL.

The impacts of incremental energy efficiency that FPL plans to implement in the future, plus the cumulative and projected incremental impacts of FPL's load management programs, are accounted for as "line item reductions" to the forecasts as part of the IRP process as shown in Schedules 7.1 through 7.4. After making these adjustments to the load forecasts, the resulting "firm" load forecast is then used in FPL's IRP work.

Schedule 2.1

Projected Values (2012 - 2021):

Col. (19) represents forecasted energy sales that do not include the impact of incremental conservation and agrees to Col. (2) on Schedule 3.3.

Col. (19) = Col. (16) + Col. (17) + Col. (18). These values are based on calendar year.

Col. (20) represents the annual average of the twelve month values.

Col. (21) = Col. (5) + Col. (8) + Col. (11) + Col. (20).

Schedule 3.1
History and Forecast of Summer Peak Demand (MW)
(Historical)

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
Year	Total	Wholesale	Retail	Interruptible	Res. Load Management	Residential Conservation	C/I Load Management	C/I Conservation	Net Firm Demand
2002	19,219	261	18,958	0	879	754	489	517	17,851
2003	19,668	253	19,415	0	892	798	577	554	18,200
2004	20,545	258	20,287	0	894	846	588	577	19,063
2005	22,361	264	22,097	0	902	895	600	611	20,858
2006	21,819	256	21,563	0	928	946	635	640	20,256
2007	21,962	261	21,701	0	952	982	716	683	20,295
2008	21,060	181	20,879	0	966	1,042	760	706	19,334
2009	22,351	249	22,102	0	981	1,097	811	732	20,558
2010	22,256	419	21,837	0	990	1,181	815	756	18,512
2011	21,618	427	21,191	0	1,002	1,252	821	776	17,767

Historical Values (2002 - 2011):

Col. (2) - Col. (4) are actual values for historical Summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) represent actual DSM capabilities starting from January 1988 and are annual (12-month) values except for 2011 values which are through August. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC), CILC, and Commercial /Industrial Demand Reduction (CDR).

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" as if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col.(2) - Col.(6) - Col.(8).

Schedule 3.1
History and Forecast of Summer Peak Demand (MW)
(Projected)

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
August of Year	Total	Wholesale	Retail	Interruptible	Res. Load Management*	Residential Conservation	C/I Load Management*	C/I Conservation	Net Firm Demand
2012	21,623	432	21,191	0	1,036	64	865	26	19,632
2013	21,931	389	21,542	0	1,048	125	884	56	19,817
2014	23,243	1,187	22,056	0	1,075	190	922	90	20,966
2015	23,786	1,194	22,592	0	1,088	257	940	123	21,378
2016	24,315	1,201	23,114	0	1,101	324	959	155	21,775
2017	24,529	1,195	23,334	0	1,114	391	978	188	21,858
2018	24,674	1,202	23,472	0	1,127	458	996	221	21,871
2019	25,041	1,210	23,832	0	1,140	526	1,015	253	22,107
2020	25,499	1,217	24,282	0	1,156	579	1,028	280	22,456
2021	25,960	1,225	24,735	0	1,172	626	1,042	303	22,816

Projected Values (2012 - 2021):

Col. (2) - Col. (4) represent FPL's forecasted peak w/o incremental conservation, cumulative load management, or incremental load management.

Col. (5) - Col. (9) represent cumulative load management, and incremental conservation and load management. All values are projected August values. The projections for 2012 through 2019 are based on the FPSC's 2011 order in the DSM Plan docket. Projected DSM values for 2020 and 2021 assume 100 MW/year of incremental DSM.

Col. (8) represents FPL's Business On Call, CDR, CILC, and Curtailable programs/rates.

Col. (10) represents a "Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

* Res. Load Management and C/I Load Management include MW values of load management from Lee County.

Schedule 3.2
History and Forecast of Winter Peak Demand:Base Case
(Historical)

2019	23,403	1,261	22,142	0	1,110	472	757	229	20,835
2020	23,667	1,269	22,398	0	1,124	522	767	254	21,000
2021	23,952	1,276	22,675	0	1,139	565	778	275	21,195

Projected Values (2012 - 2021):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation, cumulative load management, or incremental load management

Col. (5) - Col. (9) represent cumulative load management, and incremental conservation and load management. All values are projected January values. The projections for 2012 through 2019 are based on the FPSC's 2011 order in the DSM Plan docket. Projected DSM values for 2020 and 2021 assume 100 MW/year of incremental DSM.

Col. (8) represents FPL's Business On Call, CDR, CILC, and Curtailable programs/rates.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9)

* Res. Load Management and C/I Load Management include MW values of load management from Lee County.

Schedule 3.3
History of Annual Net Energy for Load (GWh)
(All values are "at the generator" values except for Col (8))
(Historical)

(1) Year	(2) Net Energy For Load without DSM GWh	(3) Residential Conservation GWh	(4) C/I Conservation GWh	(5) Actual Net Energy For Load GWh	(6) Sales for Resale GWh	(7) Utility Use & Losses GWh	(8) Total Billed Retail Energy Sales (GWh)	(9) Load Factor(%)
2002	107,380	1,682	1,499	104,199	1,233	7,443	95,523	61.9%
2003	111,784	1,773	1,619	106,393	1,511	7,386	99,496	62.9%
2004	111,659	1,872	1,693	108,093	1,531	7,467	99,095	59.9%
2005	115,065	1,970	1,793	111,301	1,506	7,498	102,296	56.8%
2006	117,116	2,078	1,901	113,137	1,569	7,909	103,659	59.2%
2007	118,518	2,138	2,066	114,315	1,499	7,401	105,415	59.4%
2008	115,379	2,249	2,126	111,004	993	7,092	102,919	60.0%
2009	115,844	2,345	2,196	111,303	1,155	7,394	102,755	56.8%
2010	119,220	2,487	2,259	114,475	2,049	7,870	104,557	58.7%
2011	117,460	2,683	2,324	112,454	2,176	6,950	103,327	59.4%

Historical Values (2002 - 2011):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula Col. (2) = Col. (3) + Col. (4) + Col. (5)

Col. (3) & Col. (4) are DSM values starting in January 1988 and are annual (12-month) values. Col. (3) and Col. (4) for 2011 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWh reductions experienced each year.

Col. (5) is the actual Net Energy for Load (NEL) for years 2002 - 2011.

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (5) - Col. (6) - Col. (7). These values are at the meter.

Col. (9) is calculated using Col. (5) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (5)*1000) / ((Col. (2) * 8760) Adjustments are made for leap years.

Schedule 3.3
History of Annual Net Energy for Load (GWh)
(All values are "at the generator" values except for Col (8))
(Projected)

(1) Year	(2) Forecasted Net Energy For Load without DSM GWh	(3) Residential Conservation GWh	(4) C/I Conservation GWh	(5) Net Energy For Load Adjusted for DSM GWh	(6) Sales for Resale GWh	(7) Utility Use & Losses GWh	(8) Forecasted Total Billed Retail Energy Sales w/o DSM GWh	(9) Load Factor(%)
2012	111,156	87	48	111,021	2,314	7,034	101,808	58.5%
2013	112,487	183	104	112,201	2,210	6,812	103,465	58.6%
2014	117,982	282	162	117,538	5,013	7,065	105,903	57.9%
2015	121,407	383	222	120,802	5,667	7,049	108,691	58.3%
2016	123,310	483	282	122,545	5,699	7,107	110,504	57.7%
2017	124,806	584	342	123,880	5,657	7,177	111,972	58.1%
2018	126,270	685	401	125,183	5,677	7,260	113,333	58.4%
2019	127,918	786	461	126,671	5,717	7,360	114,841	58.3%
2020	130,631	857	503	129,271	5,768	7,527	117,336	58.3%
2021	133,646	927	545	132,174	5,812	7,706	120,127	58.8%

Projected Values (2012 - 2021):

Col. (2) represents Forecasted Net Energy for Load w/o incremental DSM from 2012 - on. The Col. (2) values are extracted from Schedule 2.3, Col. (19). The effects of conservation implemented prior to September 2011 are incorporated into the load forecast values in Col. (2).

Col. (3) & Col. (4) are forecasted values of the reduction on sales from incremental conservation from Jan 2012 - on and are mid-year (6-month) values reflecting DSM signups occurring evenly thoughout each year.

Col. (5) is the forecasted Net Energy for Load (NEL) after adjusting for impacts of incremental DSM for years 2012 - 2021 using the formula: Col. (6) = Col. (2) - Col. (3) - Col. (4)

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (2) - Col. (6) - Col. (7). These values are at the meter.

Col. (9) is calculated using Col. (2) from this page and Col. (2), "Total", from Schedule 3.1. Col. (9) = ((Col. (2)*1000) / ((Col. (2) * 8760) Adjustments are made for leap years.

Schedule 4
Previous Year Actual and Two-Year Forecast of
Retail Peak Demand and Net Energy for Load (NEL) by Month

(1)	(2)	(3)	(4)	(5)	(6)	(7)
	2011 ACTUAL		2012 FORECAST		2013 FORECAST	
Month	Total Peak Demand MW	NEL GWh	Total Peak Demand MW	NEL GWh	Total Peak Demand MW	NEL GWh
JAN	18,552	8,061	20,889	8,291	21,101	8,429
FEB	14,483	7,228	16,965	7,420	17,137	7,547
