Florida Power & Light Company's

2015 Request for Proposals

To Meet Generation Capacity Needs Beginning in 2019

March 16, 2015

FLORIDA PUBLIC SERVICE COMMISSION
DOCKET: 150196-EI EXHIBIT: 2
PARTY: FLORIDA POWER & LIGHT COMPANY (FPL) – (DIRECT)
DESCRIPTION: Steven R. Sim SRS-1

2015 Request for Proposals - Generation Capacity

Section I - 2015 RFP Overview

A. Introduction

Florida Power & Light Company (FPL) set forth a comprehensive resource plan in its 2014 Ten Year Power Plant Site Plan (Site Plan). This plan included a mix of cost-effective demand side management (DSM) and generation resources to meet FPL's projected resource needs. The 2014 Site Plan document projected that, after all cost-effective DSM had been accounted for, FPL would have a need for additional generation beginning in the year 2019. Although a number of key forecasts have changed since those used in the resource planning work reflected in the 2014 Site Plan, FPL continues to project a significant need for new generation beginning in the year 2019. FPL currently projects a need for new generation of approximately 1,052 MW beginning in the Summer of 2019.

Therefore, FPL is initiating a Request for Proposals (RFP) process in 2015 to identify viable firm capacity and energy generation resources that will be compared to FPL's best self-build generation option; i.e., FPL's Next Planned Generating Unit (NPGU), to meet FPL's projected capacity needs beginning in 2019.

The aim of this RFP process is to obtain a variety of eligible supply-side resource proposals that can provide firm capacity, then evaluate those proposals, and/or combinations of proposals, in comparison to FPL's NPGU. This will enable FPL to select the best, most cost-effective generation resource or combination of generation resources that meets FPL's system reliability and performance standards in an environmentally responsible manner, all for the benefit of FPL's customers.

B. General Notices

1. Definition of RFP

It is important that all participants in this RFP process clearly understand that, in order to protect the interests of FPL's customers, FPL retains the right during the RFP process to: select only FPL's NPGU, or selecting FPL's NPGU in conjunction with one or more proposals, or select a proposal or combination of proposals that is, or is not, the lowest-priced generating unit, proposal, or combination, waive a non-compliance aspect in any proposal, reject any and all proposals, modify or cancel the RFP process, modify the cost and/or performance assumptions of FPL's NPGU, and modify FPL's projected need for new generation resources. In the event that FPL modifies the cost and/or performance assumptions of FPL's NPGU, those Proposers that have eligible and competitive proposals under evaluation at that time will be given an opportunity to amend their proposals with respect to only those aspects that are affected by FPL's modifications to the NPGU.

This RFP is not an offer to enter into a contract. It is a solicitation of exclusive firm offers of fixed duration from Proposers. Nothing in this RFP or any communication associated with this RFP shall be taken as constituting an offer or representation between FPL and any other party. Neither issuance of this RFP, nor the entry of FPL into negotiations with any Proposer, will be deemed to create any commitment or obligation on the part of FPL to enter into a binding agreement with any Proposer. Those entities that elect to submit proposals do so without recourse against FPL or any of its affiliates for either FPL's rejection of their proposal(s) or for failure, for any reason, of the Proposer and FPL to execute a definitive purchase agreement or tolling agreement (jointly "Purchase Agreement") related to FPL's RFP.

2. Regulatory Background

The Florida Administrative Code Rule 25-22.082 requires public utilities to issue an RFP prior to filing a petition for Determination of Need in accordance with Section 403.519, Florida Statutes. FPL's projections indicate that FPL will have a need for additional generation capacity from a reliability perspective starting in 2019, and this projected capacity need increases every year thereafter. FPL has determined that adding the most cost-effective FPL self-build option that can provide additional capacity starting in 2019 would require a Determination of Need**.** FPL recognizes that proposals that may be submitted as alternatives to FPL's NPGU may or may not require a Determination of Need.

3. Overall RFP Description

This RFP addresses FPL's projected capacity needs starting in the Summer of 2019. The RFP presents a NPGU with a June 1, 2019 in-service date. The RFP seeks alternatives with an in-service date of June 1, 2019 that can be compared to FPL's self-build option. (Proposals with earlier and later in-service dates are unacceptable.) This process will enable FPL to select the most cost-effective generation capacity resource(s) that will meet FPL's reliability and performance requirements and that can be placed in service to meet FPL's 2019 capacity need.

4. Proposal Price

All proposals must ensure their price reflects all capital costs to construct, and all O&M costs to operate and maintain, any pipeline laterals(s), railway equipment, fuel handling equipment, facility infrastructure, land costs, and any other facilities necessary to deliver the full fuel or energy requirements (including backup fuel requirements) to the proposed generating unit.

5. Types of Proposals

The solicitation is designed to accommodate a wide range of proposals for supply-side generation alternatives from various fuels, technologies, locations, and under differing commercial frameworks. For example, FPL may receive proposals for power sales under a Purchase Power Agreement from existing facilities (currently in operation) and newly constructed facilities (greenfield or brownfield offerings). These proposals may have fuel supply and firm transportation arrangements or request a natural gas tolling arrangement where FPL would provide the natural gas supply and firm transportation. A reasonable attempt will be made to accommodate creative variations that may be proposed. Nonetheless, it is conceivable that a Proposer may offer a unique attribute that has not been explicitly considered in this RFP and the associated forms. In that instance, FPL will contact the Proposer to understand, and if possible, evaluate the unique features of a particular offering.

FPL will not consider or evaluate proposals to sell an existing, or new (turnkey project) generating unit to FPL. FPL will not consider or evaluate proposals from specific units that use coal or petroleum coke as fuel. However, FPL will consider and evaluate proposals of system sales that include units that use coal or petroleum coke as a fuel, subject to the conditions specified below in section III, 7 below.

6. Firm Capacity and Dispatchability

FPL seeks proposals that would allow FPL to meet its firm capacity requirement in future years. Therefore, all proposals will be required to offer the commitment of firm capacity and energy to FPL. FPL defines Firm Capacity and Energy as follows:

> *"All electric energy and capacity owned or acquired by the Proposer to be made available exclusively to FPL pursuant to the RFP as if FPL owned the generating capacity on its own system. Firm Capacity and Energy shall not include any electric generating capacity that another Party, including the Proposer, can utilize or purchase."*

The firm capacity and energy proposed in any proposal must be fully dispatchable under the operational control of FPL and must include all of the facility's output, inclusive of ancillary service products and environmental attributes. Requiring that all proposals satisfy the firm and dispatchability conditions ensures that proposals can be evaluated on an equal basis regarding their total costs and reliability benefits to FPL's customers.

C. Description of Appendices

There are five appendices to this 2014 RFP that are summarized below.

Appendix A provides a copy of FPL's 2014 Ten Year Power Plant Site Plan.

Appendix B lists key conditions that will be incorporated into any Power Purchase Agreement (PPA) that may be entered into as a result this RFP.

Appendix C provides the specific forms that Proposers will need to submit as part of their proposals, and a description of the information that must be provided in those forms.

Appendix D provides detailed information regarding FPL's evaluation methodology, including examples of how specific evaluation calculations will be applied.

Appendix E discusses changes in key forecasts from those utilized in the development of FPL's 2014 Ten Year Site Plan (provided in Appendix A). The current forecasts will be used in the evaluation of the NPGU and proposals submitted in response to this RFP and have been used in the evaluation of FPL's NPGU. This appendix also discusses key changes to FPL's resource plan, compared to the resource plan discussed in FPL's 2014 Ten Year Site Plan, up to the year 2019.

D. Projected RFP Schedule

FPL envisions that the milestone schedule for the RFP process will be as described below in Table I.D below. FPL reserves the right to change the schedule at its sole discretion.

Table I.D Schedule of Milestones

Milestone	Date
• RFP Pre-Issuance Discussion Meeting	March 9, 2015
• Release RFP Document	March 16, 2015
• Pre-Bid Workshop	March 24, 2015
• Cutoff Date for RFP Questions	April 17, 2015
• Proposals Due	May 15, 2015
• Short List Announcement – if relevant	TBD
• Permitting Activity Commences	TBD
• Best and Final Offers Due – if relevant	TBD
• Initial Negotiations – if relevant	June 15 to July 30, 2015
• Selection Announced (on or before)	July 31, 2015

Note: The above dates are projections. All dates are subject to change at FPL's sole discretion to accommodate unforeseen delays or required procedural actions. Certain dates are listed as TBD because these dates are heavily dependent upon the number, type, and/or complexity of eligible proposals that will be received and evaluated.

E. Pre-Bid Meeting, RFP Notices, and Addenda

1. Pre-Bid Meeting

FPL will hold a Pre-Bid Meeting in the Miami, Florida area. The meeting will be on Tuesday, March 24, 2015 beginning at 9:30 a.m. at the InterContinental At Doral, 2505 NW 87th Avenue, Doral, Florida 33172-1610. The hotel's phone number is 305-468-1400. Interested parties may attend in person or remotely via a conference call connection. Regardless of whether an interested party plans to attend in person or remotely, the party must first register for the meeting on FPL's RFP website at FPL.com/2015rfp. This meeting is scheduled to conclude by 12 p.m. The purpose of the Pre-Bid Workshop is to assist Proposers in understanding the submittal requirements, provide background on FPL's most recent resource planning results, and begin to respond to questions from potential proposers.

2. RFP Notices and Addenda

RFP-related notices and addenda will, as needed, be posted on the RFP website. In addition, all RFP-related questions posed to FPL, along with FPL's responses to those questions, will also be posted on the RFP website.

Section II - General Information

A. Issues Influencing Evaluation Regarding System Costs, Environmental Impacts, and Reliability

1. Geographic Location

System cost-effectiveness and reliability measures are improved when new generation units are located near the system load center. The ability of a generator to deliver power in or near the area of greatest need lowers the cost of delivering that power to customers and provides greater operational flexibility for the system. FPL's RFP evaluation methodology recognizes the value of geographic location and this is discussed in more detail in Appendix D.

2. Greenhouse Gas (GHG) Emissions

FPL's evaluation process will examine the projected impacts of proposals (and FPL's NPGU) on FPL's system emissions including GHG emissions (as represented by carbon dioxide, CO2). GHG emission-related costs to the FPL system will be addressed as discussed in Appendix D.

3. Fuel Diversity

FPL's has always sought to maintain a generation system that utilizes a diverse range of fuel sources in order to ensure reliable service to its customers. For example, FPL's NPGU would receive natural gas through the new Sabal Trail and Florida Southeast Connection pipelines, which would enable FPL to obtain natural gas from diverse geographic locations.

In addition to FPL's economic analyses of proposals and FPL's NPGU, FPL's RFP evaluation process will also generally recognize the value offered by fuel diverse generation options in the context of the non-economic evaluation of environmental and technical or operational factors. The non-economic aspects of a proposal, including fuel diversity, will be appropriately balanced with the economic aspects of the proposal, during the overall evaluation process.

B. Proposer Responsibilities

1. Regulatory Compliance

The Proposer is solely responsible for acquiring and maintaining compliance with all licenses, permits, and other regulatory approvals (including environmental) that will be required by current or future federal, state, or other local government laws, regulations, or ordinances to successfully implement the proposal. For a selected proposal that requires new power plant construction falling under the Florida Electrical Power Plant Siting Act, Section 403.501 – 403.518, Florida Statutes (Siting Act), FPL would be a co-applicant in a Determination of Need filing with the Florida Public Service Commission under Section 403.519, Florida Statutes. FPL will cooperate with any selected Proposer(s) to provide information or such other assistance as may reasonably be necessary for the Proposer(s) to satisfy licensing and regulatory requirements. Likewise, the selected Proposer(s) shall fully support all of FPL's regulatory requirements associated with this potential capacity and energy arrangement.

For any proposal that requires new power plant construction falling under the Siting Act, the Proposer must demonstrate as part of the proposal a permitting and construction schedule that allows the new plant to be in commercial operation on or before the Capacity Delivery Date. Appendix C includes a discussion of Form # 7 that requires, in part, key milestone dates regarding permitting and construction schedules.

2. Development Activities

The Proposer is solely and completely responsible for the location, acquisition, and development of the plant site and other land or infrastructure that is needed for any proposed new generating units.

The Proposer is also completely responsible for securing, locating, or guaranteeing any emissions allowances, credits, or offsets which may be required by the Title IV Clean Air Act Amendments, Clean Air Interstate Rule, Clean Air Mercury Rule or other federal, state, or local requirements, or otherwise complying with environmental regulations to allow the construction and/or operation of the proposed facility. Proposers whose proposals offer the sale of capacity and energy from an existing power plant(s) must secure the emission allowances, credits, or approvals necessary, or in otherwise complying with environmental regulations to operate the facility during the term of the contract.[1]

3. Project Funding and Costs

All Proposers are completely responsible for all financing activities related to the project and for engineering, design, procurement, and construction of all aspects of the facility. These include, but are not limited to: the cost of the land, the power block, environmental control systems, fuel delivery systems (from the fuel delivery point, if a tolling arrangement is proposed), and transmission system interconnections. The Proposer is also completely responsible for sourcing and contracting for a reliable fuel supply and firm fuel transportation (unless the proposal is a gas tolling proposal) and any other activity required for the reliable delivery of firm capacity and energy to FPL at the identified delivery or interconnection point. All costs associated with the design, construction, operation, and maintenance of the transmission interconnection facilities (including but not limited to generator step-up transformers and high-voltage breakers) and natural gas pipeline laterals associated with the delivery of firm capacity and energy to FPL will be the responsibility of the Proposer.

4. Interconnection and Transmission Service

The Proposer must secure with the appropriate transmission provider(s) all needed transmission facilities and arrangements required to deliver the firm capacity and energy to the FPL transmission system on a firm long-term basis for the entire term of the proposal. Per FPL's OATT, the Proposer will also be responsible for funding (on a reimbursable basis) any network upgrades to FPL's transmission system that are necessitated by the purchase of capacity and energy form the Proposer's resource.

5. Cooperation

Any selected Proposer(s) agrees by the act of submitting a proposal in response to this RFP to file, as needed, an application under the Siting Act and to fully

[1] Due to uncertainty regarding GHG regulations and costs, a projection of GHG $/ton costs (represented by projected CO_2 costs) will be used in the evaluation of proposals and the NPGU regarding their projected impacts on system GHG emissions and costs. The treatment of GHG regulation-based operational costs in a potential power purchase agreement will be addressed in negotiations for such an agreement. However, FPL and its customers will not agree to pay the Proposer for any GHG emission costs due to GHG emission rates higher than the guaranteed rates submitted by the Proposer and must take into consideration any free GHG emission allowances or credits that are ultimately allocated to the Seller/resource under environmental law. In the event of a future change in law or regulation that would have the effect of shifting to or imposing upon FPL GHG emission costs greater than those agreed to in the PPA, FPL would have the right to terminate the PPA if such additional costs were not found to be prudent and approved for FPL cost recovery by the Florida PSC.

support, as requested by FPL, any FPL regulatory proceeding(s) related to firm capacity purchases emanating from this solicitation. Proposers shall be responsible for all of Proposer's costs to participate in the necessary regulatory proceedings.

C. Contact Person and Confidentiality

1. FPL Contact Person

Name: Steven Sim
Florida Power & Light Company
Department: Resource Assessment & Planning/RAP
Street Address: 9250 W. Flagler Street
City/State/Zip Code: Miami, Florida 33174
Email: steve.r.sim@fpl.com
Office Phone: 305-552-2246
Fax: 305-552-2716

FPL's evaluation of all proposals and FPL's NPGU will be reviewed, and a parallel evaluation will be conducted, by Sedway Consulting, Inc. Therefore, please copy Alan.Taylor@sedwayconsulting.com on all RFP-related questions and emails to FPL. All answers to questions will be provided solely on FPL's RFP website.

2. Proposal Confidentiality

FPL will take reasonable precautions and use reasonable efforts to protect proprietary and confidential information contained in a proposal, provided that such information is clearly identified by the Proposer as Proprietary and Confidential on each page(s) on which the information appears.

To clearly identify confidential information, the Proposer must (1) stamp each such page with the label "**Confidential Information**" and (2) highlight/shade the specific confidential information contained on the pages stamped "**Confidential Information**". (A blanket statement that an entire page or proposal is proprietary and confidential will not be considered clear identification.)

Notwithstanding the foregoing, FPL shall disclose Confidential Information in the event that it determines, in its sole discretion, that disclosure is necessary in order to comply with any applicable law, order, regulation, ruling, subpoena, or order of the Florida Public Service Commission or other governmental authority or tribunal with competent jurisdiction. Such disclosure may include, but is not limited to, production of Confidential Information to the Florida Public Service Commission and to parties in legal and regulatory proceedings conducted to consider and to approve the project(s) which is the subject of this Request for Proposals.

In the event that FPL is requested or required to disclose any Confidential Information, FPL will provide prior notice to the entity whose Confidential Information has been requested so that such entity may, if it chooses, seek an appropriate protective order subject to protections available under the Florida Statutes, Florida Administrative Code, and Florida Rules of Civil Procedure.

With respect to any disclosure made by FPL pursuant to the foregoing paragraphs, FPL will furnish only that portion of the Confidential Information that FPL determines in its sole discretion to be consistent with the scope of the subpoena, demand, or request and will seek reasonable assurances that confidential treatment will be accorded such Confidential Information.

Section III. Minimum Requirements for Proposals

Proposers must agree, both in their proposals and as part of any Power Purchase Agreement arising from this RFP, to comply with (as applicable) each of the provisions of the Minimum Requirements for Proposals listed in this Section III, and of the Minimum Requirements Pursuant to Purchase Agreement listed in Section IV. Failure of a Proposer to agree to and/or comply with (as applicable), or failure of a proposal to agree with or comply with one or more Minimum Requirements for Proposals or Minimum Requirements Pursuant to Purchase Agreement, will be grounds for determining a proposal ineligible. FPL reserves the right to waive inconsequential non-compliance with these Minimum Requirements. Proposals determined to be ineligible will be returned to the Proposer along with a refund of 50% of the RFP Evaluation Fee.

1. Financial Viability Requirements of Proposers

For each proposal submitted pursuant to FPL's RFP, the Proposer or Qualified Guarantor of the Proposer must have a senior unsecured debt rating of no less than "BBB-" from Standard & Poor's, or"Baa3" from Moody's Investors Service with a "stable" outlook, and be able to satisfy the Completion and Performance Security requirements set forth in section 8 below.

Each proposer must certify (as part of its proposal) that there are no pending legal or civil or regulatory actions that could affect the ability of the Proposer to maintain an acceptable debt rating consistent with the above criteria.

2. Experience of Proposer

Proposers whose proposal reflects (i) the construction of a new generating unit, or (ii) an upgrade to an existing generating unit (each a "New Unit") must demonstrate that it has successfully executed the development, permitting, design, procurement, construction and commissioning of a project similar to that reflected in the proposal.

The entity that will operate and maintain the proposed generating unit(s) submitted pursuant to FPL's RFP must demonstrate that it has a minimum of 5 years of experience in the successful, reliable operation and maintenance of generating units utilizing similar technology. The success and reliability of operations may be demonstrated through operational records and/or NERC GADS reporting data as requested in Appendix C, Form # 4.

3. Proposal Submission Requirements

All proposals and variations to proposals must be received by the FPL RFP Contact Person by 4:00 p.m., Eastern Daylight Savings Time, on May 15, 2015 (Proposal Due Date and Time). Proposers must submit five (5) bound hard copies, plus an electronic copy of the completed forms on a CD, by the Proposal Due Date and Time. The RFP Evaluation Fee and/or Variation Fee, must accompany each proposal and, separately, each proposal variation.

All forms specified in the RFP must be submitted by the Proposer, and the information requested therein must be complete and accurate. FPL may choose to contact a Proposer to request that omitted or incomplete information be provided, but is under no obligation to do so. Any attempt by a Proposer to disclaim generally the terms and conditions of this RFP without stating specific exceptions and alternative language will be grounds for determining a proposal to be incomplete, and therefore, ineligible.

Proposer must comply with the Publication Notice requirement of Rule 25-22.082(7), Florida Administrative Code, which requires a notice to be published in a newspaper of general circulation in each county in which the Proposer intends to build a new electric generating unit or upgrade an existing electrical generating unit. The Publication Notice shall be at least one-quarter of a page and shall be published not later than 10 days after the Proposal Due Date. The Publication Notice shall state that the Proposer has submitted a proposal to build a new electric generating unit or upgrade an existing electrical generating unit, and shall include the name and address of the Proposer submitting the proposal, the name and address of the public utility that solicited the proposals, and a general description of the proposed new or upgraded generating and its location. A copy of the notice, including an affidavit confirming publication, must be submitted to the FPL Contact Person within 10 days of publication of such notice, or within 20 days of the Proposal Due Date.

4. RFP Evaluation Fee

Each proposal must be accompanied by a non-refundable check of $25,000 ("RFP Evaluation Fee") made out to "Florida Power & Light Company" and delivered to the FPL RFP Contact Person on or before the Proposal Due Date (no later than 4:00 p.m. EDST). If more than one proposal is submitted by a specific Proposer, then a separate, non-refundable $25,000 fee must accompany each proposal. Proposals deemed ineligible or otherwise non-responsive after an initial review will not be evaluated further and 50% of the Evaluation Fee will be refunded.

One proposal consists of a specific combination of a site, technology, fuel source, total capacity level, term (*e.g.*, 10 years), and pricing submittal. If a Proposer submits variations of term and/or price related to a specific proposal (a single variation is defined as a change in one or both term and/or price), the Proposer must accompany such variations with an additional check for $5,000 per variation (the Variation Fee). There are no limitations to the number of price/term variations submitted, as long as each variation is accompanied by a separate $5,000 Variation Fee.

Changes in site, technology, fuel source, or capacity level, or in any parameter other than term or price will constitute a separate proposal and will require a separate full $25,000 RFP Evaluation Fee. Any proposals and the related variations that are deemed by FPL to be ineligible or non-responsive (as determined by FPL at its sole discretion) will not be evaluated further and 50% of the applicable fee(s) received will be refunded.

5. Term of the Proposal

Proposals must offer to deliver firm capacity and energy beginning on June 1, 2019, and throughout the term specified in the proposal (the "Proposal Term"). The acceptable proposal terms for proposals are as follows:

i. The minimum proposal term for proposals offering system sales or sales from new or existing units that do not require a need determination is five (5) years.
ii. The minimum proposal term for proposals offering PPA or Tolling sales from a new unit that requires a need determination is ten (10) years.
iii. The minimum term length for proposals requiring a Natural Gas Tolling Agreement is fifteen (15) years.

iv. The maximum proposal term of any proposal is thirty (30) years.

6. Range of Acceptable Proposals

FPL will consider a power purchase agreement pursuant to which FPL would purchase firm capacity and energy from:

i. An existing generating unit that is currently in operation and that satisfies (in whole or in part) FPL's projected 2019 generation needs ("Existing Unit"); and
ii. A New Unit that satisfies (in whole or in part) FPL's projected 2019 generation needs.

FPL will also consider a gas Tolling Agreement pursuant to which FPL would deliver natural gas and purchase firm capacity and energy from:

a. An Existing Unit that satisfies (in whole or in part) FPL's projected 2019 generation needs, and
b. A New Unit that satisfies (in whole or in part) FPL's projected 2019 generation needs.

FPL will also consider a purchase from a system sale subject to the conditions specified below in section 7 below.

FPL will not consider or evaluate proposals to sell an existing, or new (turnkey project) generating unit to FPL. FPL will not consider or evaluate proposals from specific units that use coal or petroleum coke as fuel. However, FPL will consider and evaluate proposals of system sales that include units that use coal or petroleum coke as a fuel, subject to the conditions specified below in section 7 below.

7. System Sales

Proposals that consist of system sales will be considered only if such system sales are: (i) from electric systems that are subject to the jurisdiction of the Florida Public Service Commission ("FPSC") (or similar public regulatory authority), (ii) have direct control of generation and transmission facilities, and (iii) are members in good standing of a NERC reliability coordinating council.

Proposers that offer firm capacity and energy sales from system sales must provide a clear explanation of how the firm capacity and energy will be produced, scheduled, and delivered to FPL.

Proposers that offer firm capacity and energy system sales must also describe how the Proposer's commitment of such firm capacity to FPL would affect the

Proposer's own reserve margin, and explain how the Proposer's reserve margin will remain above the minimum reserve margin criteria approved for the Proposer by the FPSC or similar public regulatory authority.

8. Firm Capacity Nature of Proposal

i. Proposals must offer firm capacity solely to FPL year-round.
ii. Proposed firm capacity and energy must be fully dispatchable under the operational control of FPL for all proposals except those that are system sales.
    a. With respect to proposals for sales from a generating unit with capacity greater than 100 MW, such unit must be equipped with automatic generation control ("AGC") that can be directed remotely by FPL.
iii. Proposals offering firm capacity and energy from an identifiable unit (*i.e.*, not a system sale) must dedicate to FPL all of the unit's output, including any ancillary service products and environmental attributes.
    a. No portion of the output of the proposed generating unit shall be available to any third party, nor to the Proposer.
iv. The firm capacity and energy delivery must commence within the required time frame of the solicitation and remain as firm capacity and energy throughout the term of the proposal.
v. Capacity and energy from a system sale must be delivered to FPL when called upon by FPL based on FPL's own economic dispatch.

9. Permit and Authorization Feasibility

The Proposer must demonstrate that there are no significant barriers to obtaining the necessary regulatory and governmental permits and authorizations to execute or implement the proposed project on a schedule that meets the Capacity Delivery Date. All proposed projects will be subject to the approval of the appropriate Regulatory Authorities.

The Proposer is responsible for acquiring and maintaining compliance with all licenses, permits, and other regulatory approvals (including environmental) that will be required by current or future federal, state, or other local government laws, regulations, or ordinances to successfully implement the proposal during the Proposal Term.

10. Binding Nature of Proposal

Each proposal must be firm and binding, and must be certified (as part of the proposal) as a "binding, definitive proposal" by an Officer of the proposing entity. "Indicative" proposals are not eligible for consideration and will be rejected.

The terms of each proposal must remain valid and binding for 180 days from the Proposal Due Date, unless the proposal is withdrawn in full. Proposals cannot be modified, except where modified specifically in response to a modification of FPL's description of its NPGU, or in response to FPL's explicit invitation for a Proposer to submit a Best and Final Offer ("BAFO"). Clarifications requested by FPL are not considered modifications.

If FPL selects a proposal for a "Short List" and invites the selected Proposer to submit a BAFO, such BAFO (or the original proposal if the Proposer elects to remain with the original proposal) must then remain valid and binding for 180 days from the date the Proposer submits a BAFO.

11. Identifiable Capacity Source

The proposal's firm capacity and energy must be from one or more specific generating unit(s) that is/are clearly identified and described in detail in the proposal.

Exceptions to this requirement will be made for system sales from electric systems that are subject to the jurisdiction of the FPSC or similar public authority, have direct control of generation and transmission assets, and are members in good standing of a NERC reliability coordinating council. Firm capacity and energy sales from systems must include a clear explanation of how the capacity is to be obtained and delivered. The proposal must also explain how commitment of such system capacity to FPL will affect the Proposer's ability to meet the FPSC reserve margin requirements (or the requirements of other state agencies as appropriate).

12. Site Description

With respect to a proposed new generating unit, the Proposer shall provide a detailed description of the site on which the unit is proposed to be built including, but not limited to, the exact location of the site, the required transmission interconnection, fuel delivery system(s), and water resources to be used by the Proposer in operating the resources, and any other site or project characteristics that affect the capacity and energy values associated with the proposal.

FPL will not consider any proposals that would use property owned or controlled by FPL.

13. OATT Requirement

All generating units reflected in proposals must be located within FPL's transmission system and be interconnected to FPL's transmission system or, if located outside FPL's system, must have accounted for all interconnection and system upgrades necessary to allow the generating unit to qualify as a designated network resource (pursuant to FPL's OATT).

In order to be considered, each Proposer submitting a proposed, new generating unit to be located within FPL's system must also submit, as applicable, at least 15 days prior to the Proposal Due Date, a completed "Large Generator Interconnect Request" application and a security deposit (as applicable) in accordance with the provisions of FPL's OATT. To evidence that the application and security deposit have been submitted, the Proposer must include a copy of the OASIS request confirmation statement with the proposal.

14. OEM Parts for Critical Components

Proposers whose proposals are based on natural gas-fired combustion turbines and/or combined cycle units will be required to represent that, if selected, the proposed generating unit will install and continue to use original equipment manufacturer (OEM) parts for gas turbine hot path components listed below:

- Rotor Discs, Spacers, and Stud Assembly Hardware (e.g., Turbine Thru Bolts, Nuts, and Washers)
- Turbine Stationary Airfoils (e.g., Vanes/Nozzles/Diaphragm)
- Turbine Rotating Airfoils (e.g., Blades/Buckets)
- Turbine Vane Support Rings or Vane Carriers

Any power purchase arrangement entered into pursuant to the RFP will reflect this OEM commitment, and the OEM parts will be installed prior to the start of the purchase arrangement. On an annual basis, the Proposer will be required to obtain a certification from the equipment manufacturer(s) to the effect that OEM parts have been installed and maintained in accordance with the requirements of the purchase arrangement entered into pursuant to this RFP.

Failure to install and properly maintain such OEM parts, or to obtain and deliver to FPL OEM's annual certification, will place the selected Proposer in default, with 120 days to cure. If not cured, FPL may terminate the Purchase Agreement and or collect damages as specified in the Purchase Agreement.

15. Resource Block Size (MW) Range

The minimum power block size associated with a generating unit ("Power Block") that FPL will consider in a proposal is 50 MW. The maximum Power Block size that will be considered for a proposal is 1,650 MW (Summer).

16. Security Requirements

i. By submitting a proposal, a Proposer agrees to provide Completion Security and Performance Security as specifically defined in section IV, 8 of this document.
ii. For proposals supported by existing facilities, Proposer must agree to provide the Performance Security as specifically defined in section IV, 8.
iii. Proposer must certify that there are no pending legal or civil actions that would affect the ability of the Proposer and/or its guarantor to maintain the criteria identified in section IV, 8.

17. Proposal Pricing and Fuel Supply, Transportation, and Delivery Choices

Except as set forth in subsection i. below in regard to GHG costs, a proposal's price must reflect an "all in" contract price (including any related fees and expenses) that FPL would pay to the selected Proposer for all aspects related to, and products (including ancillary services and environmental attributes) associated with the generation and delivery to FPL of firm capacity and energy, including without limitation:

i. Payments related to all costs, fees, and expenses incurred by Proposer to maintain compliance with all laws and regulations applicable to Proposer's generating unit(s) during the Proposal Term. This includes, but is not limited to, the costs of all equipment, development, design, construction, commissioning, and all costs of meeting and maintaining compliance with environmental regulations that are in effect as of the Capacity Delivery Date or are known as of the Capacity Delivery Date to be in effect during the pendency of a PPA that would result from selection of the proposal. Due to the uncertainty currently existing in regard to GHG costs, the treatment of GHG regulation-based operational costs in any power purchase agreement would be addressed in negotiations for such an agreement.

ii. Payments related to all capital and O&M costs incurred by Proposer. This includes, but is not limited to, costs to transport natural gas from the Proposer-designated interstate pipeline to the proposed generating unit. This requirement applies to all PPAs, including natural gas tolling or non-tolling agreements.

iii. Payments related to all costs, fees, and expenses the Proposer would incur related to the purchase of fuel, delivery of fuel to Proposer's generating unit, and inventory of fuel to support operation of Proposer's generating unit.

iv. Payments related to all costs for transmission facilities (and any necessary transmission upgrades) the Proposer would incur to enable its proposed generating unit to interconnect to the FPL system and deliver firm capacity and energy to a receipt point on FPL's system acceptable to FPL.

v. FPL will not make any payments not reflected in the proposal pricing other than those for GHG emission costs agreed to in negotiations.

vi. Proposers of Natural Gas Tolling arrangements must acknowledge and agree that Proposer will post additional security to cover costs that may arise from any firm gas transportation agreement entered into by FPL to support the project in the event of a Proposer, then Seller's, default.

If a Proposer offers to provide its own fuel supply, the proposal price must also include all costs for the required amount of firm fuel transportation and delivery. The Proposer must also provide evidence of feasibility documenting arrangements that support the above fuel transportation and delivery costs. The proposal must also guarantee these fuel transportation and delivery costs and demonstrate credit support for the guarantee that is satisfactory to FPL.

If a Proposer wishes FPL to use Proposer's fuel commodity costs – instead of FPL's projected fuel commodity costs – in the evaluation of its proposal, the Proposer must also provide evidence of feasibility documenting the basis for Proposer's fuel commodity costs, and must also guarantee these fuel commodity costs for the proposed contract term and demonstrate credit support satisfactory to FPL for such guarantee.

vii. The proposed prices must be presented in the format specified in Appendix C, Form # 5.

18. Proposal Transmission Requirements

i. For proposals with generation located outside of the FPL system, FPL will not accept any proposal that requires FPL to secure firm transmission service and any associated rights, as this shall be a responsibility of the Proposer. Proposed prices must include all costs of delivering capacity and energy to the Proposer-designated FPL System Receipt Point. Form # 5 in Appendix C requires the Proposer’s projection of transmission losses (MW) associated with the third party transmission service that was used by the Proposer in developing the proposed prices.

ii. Transmission interconnection costs to connect the proposed units to the FPL system, or to a third party system, must be included in the proposal price and separately identified in Appendix C, Form # 5.

iii. Transmission integration costs on the FPL system and the costs of energy and capacity losses within the FPL system will be developed by FPL during the economic analysis of eligible proposals and resource plans and should not be included in the proposal price.

iv. To the extent a RTO or ISO or similar arrangement is implemented in Florida, proposers should note that the FPL System Receipt Point shall be defined as the location where the facility (or a third party transmission system if the facility is not in FPL territory) connects with the FPL system.

19. Dual Fuel Capability for Natural Gas-Fired Proposals

Based on the impact of hurricanes and other unforeseeable events on the production and transport of natural gas, FPL considers that, for newly built natural gas-fired generation proposals, the fuel continuity and operability characteristics of on-site distillate fuel oil capability as a backup fuel source is the most effective approach to meet system reliability and service continuity needs. Just as FPL's NPGU has on-site distillate fuel oil capability, all proposals based on New Unit additions designed to operate on natural gas as primary fuel must include the capability to operate on distillate fuel oil as a backup fuel, while complying with all applicable regulations, to satisfy system reliability and service continuity needs.

Proposals supported by such new unit gas-fired generation, and the specified prices for such proposals, shall reflect the necessary equipment to meet the following backup fuel continuity and operability characteristics. The distillate fuel oil inventory must be: immediately accessible to the new unit, sized to provide seventy-two (72) hours of continuous operation at full capacity (as rated on distillate oil) at a minimum, and must be independent of the primary fuel supply. The new unit must be able to start up on distillate fuel oil and operate at full capacity for a minimum of 72 continuous hours while complying with all applicable regulations. Additionally, the new unit must be able to make the transition from natural gas fuel supply to distillate fuel oil supply without disconnecting electrically from the transmission grid. Test demonstrations of these capabilities will be required as a condition in any PPA that might be signed between FPL and the Proposer. These are the same continuity and operability requirements that FPL requires of its own NPGU.

Due to the sequence of the permitting process, FPL recognizes that Proposers will be unable to ascertain, by the Proposal Due Date, the success of permitting the facility for full use of distillate fuel oil capability. However, a selected Proposer will be required to obtain permits and authorizations necessary to support a minimum of 500 hours of operation per year on distillate fuel oil as a contract obligation.

20. Project Milestone Schedule

All Proposers must agree to meet all applicable Critical Milestone dates presented below. FPL retains the right to terminate negotiations if a Finalist with whom FPL is negotiating a contract fails to meet the filing dates scheduled for the Site Certification filing, Air Permit filing, or Interconnection Application filing. The remaining milestones would be a part of any contract entered into by FPL as a result of this RFP and are referenced below as months prior to (-) the Capacity Delivery Date (CDD):

Site Certification Application Filed	CDD - 39 months
Air Permit Application Filed	CDD - 39 months
Interconnection Application Filed	CDD - 39 months
Irrevocable Orders Placed for Major Equipment	CDD - 28 months
Fuel Transportation Agreement(s) Executed	CDD - 24 months
Contractor Mobilized, Financing Closed	CDD - 20 months

Section IV. Minimum Requirements of Selected Proposer Pursuant to Purchase Agreement

1. General Minimum Purchase Agreement Requirements

Site Acquisition and Development

A selected Proposer shall be responsible for the location, acquisition, development, and permitting of the Proposer's own site where the proposed generating unit is to be constructed (if applicable). The selected Proposer shall also establish "site control" and demonstrate to FPL's satisfaction that Proposer has "site control" for the Proposal Term by the Proposal Due Date. The selected

Proposer shall procure adequate water resources to operate the generating unit during the Proposal Term and demonstrate to FPL's satisfaction that Proposer has adequate water resources to operate the generating unit for the Proposal Term.

Licenses and Permits

A selected Proposer will be solely responsible for obtaining and maintaining all licenses, permits, and approvals required now, or in the future, by current or future federal, state or local government laws, regulations or ordinances, to construct, upgrade, operate and maintain the Proposer's proposed generating units (including a Site Certification under the Florida Power Plant Siting Act (the "Siting Act"), if applicable), as well as maintaining compliance with all laws and regulations applicable to Proposer's generating units during the Proposal Term.

Emission Allowances, Credits and Offsets

A selected Proposer will be solely responsible for securing, locating, or guaranteeing any emission allowances, credits, or offsets which may be required by any law, regulation, or government agency. Proposer shall be solely responsible for paying any costs related to emissions from Proposer's unit(s) other than those GHG emission costs agreed to in the PPA.

Project Funding and Costs

A selected Proposer will be solely responsible for any necessary financing with respect to all aspects of the proposed generating unit(s). All costs associated with the design, construction, upgrade, operation, and maintenance of the generating units including, but not limited to, (i) the power block, (ii) environmental control systems, (iii) fuel delivery systems (including natural gas pipeline laterals), (iv) transmission facilities and upgrades (including, step-up transformers and high voltage breakers) necessary to interconnect to FPL's system will be the sole responsibility of a selected Proposer. A selected Proposer will be permitted to assign the Purchase Agreement as collateral for any financing or refinancing of the generating units with the prior written consent of FPL and pursuant to a form of consent acceptable to FPL in its sole discretion.

Fuel Supply

Except with respect to a proposed gas Tolling Agreement, a selected Proposer will be solely responsible for maintaining reliable fuel supply (primary and backup fuel) that is delivered to the Proposer's proposed generating unit(s) to ensure reliable delivery of firm capacity and energy to FPL at the specified delivery point on FPL's system.

Interconnection and Transmission

A selected Proposer is solely responsible for securing all necessary transmission facilities and rights necessary for delivering firm capacity and energy to FPL at the specified delivery point on FPL's system. The Proposer would acknowledge that the Purchase Agreement will be between (i) Proposer and (ii) FPL, acting solely in its power procurement function, and that Proposer would have no rights against FPL under the Purchase Agreement with respect to any relationship between the parties in which FPL is acting in its capacity as transmission owner, including orders or instructions relating to Electric System Upgrades and/or curtailments.

Dispatch, Control, Operation and Maintenance of the Generating Unit

i. Proposer shall at all times operate the generating unit consistent with FPL's dispatch and control instructions. Control shall be either by Proposer's manual control pursuant to FPL's oral or written directions, or by Automated Generation Control by FPL's system control center for units with capacity greater than 100 MW, unless otherwise explicitly agreed to by FPL.

ii. During the term, Proposer shall employ qualified and trained personnel for managing, operating, and maintaining the generating unit and shall ensure that such personnel are on-duty 24 hours per day, each day, throughout the term of the agreement.

iii. Proposer shall be responsible for compliance with all applicable NERC regulations and requirements.

iv. Proposer shall operate and maintain the generating unit in accordance with good engineering and operating practices, including all applicable environmental requirements. Proposer shall operate the generating unit with all automatic controls (except Automatic Generation Control) and have appropriate protection equipment in service whenever the generating unit is connected to, or operating in parallel with, the FPL system. Automatic Generation Control shall be operated pursuant to FPL's direction.

v. On an annual basis, Proposer shall submit to FPL preliminary, desired outage schedules for the following five years, and a detailed plan for the next year. FPL shall notify Proposer if the outage schedule is accepted, or will cooperate reasonably with Proposer to agree upon a revised schedule. Under no circumstances will outages be scheduled during peak months.

Exclusivity

During the Proposal Term, Proposer shall have no right to sell energy, capacity, ancillary services or environmental attributes generated by the generating unit to any third party.

Testing and Capacity Rating

i. A capacity test will be required to demonstrate commercial operation and such test results must be satisfactory to FPL in all respects.

ii. FPL, in its sole discretion, may require Proposer to perform an annual summer period capacity test and an annual winter period capacity test. In addition, a capacity test will be required in the event Proposer is (A) unable to comply with any material obligation under the Purchase Agreement for a period of 30 days or more as a consequence of an event of Force Majeure, or (B) at any time should Proposer fail, on two consecutive times, to satisfy the operating levels set by FPL dispatch instructions. Upon completion of a capacity test, the available capacity will be the lower of the demonstrated capacity or committed capacity, but in no case shall it be less than the minimum contract capacity.

Role in Regulatory Proceedings

A selected Proposer that proposes a new unit that is subject to the Siting Act shall apply to obtain a Determination of Need from the FPSC and, at Proposer's sole cost and expense, shall satisfy all requirements imposed by the FPSC, as well as fully support FPL in its role as co-applicant in the Determination of Need proceeding.

2. Generating Unit Operating Characteristics

i. **Operating Characteristics** Generating units must achieve and maintain operation at the proposed level of availability, reliability, heat rate and capacity, as well as satisfy the proposed cold start time and ramp rate, all of which shall be guaranteed by the Proposer or, if applicable, the Qualified Guarantor. If the unit in a selected proposal fails to achieve the availability, reliability, capacity, and/or heat rate levels reflected in the proposal and guaranteed in the PPA, the Proposer would be subject to liquidated damages. The selected Proposer will have 120 days to cure the problem. If not cured, FPL may terminate the PPA

   a. A proposal will be rejected if:

      1. The demonstrated average, actual availability of an Existing Unit over the past five years is less than 85%;

2. With respect to a new unit, the demonstrated average, actual availability of Proposer's similar existing units over the past five years is less than 85%; or
3. With respect to an existing unit or a new unit, the guaranteed availability submitted with the proposal is less than 85%.

b. A proposal with a CC unit will be rejected if any of the EFOR levels below is above 4.2%:
   1. The demonstrated average, actual EFOR of an existing unit over the past five years is above 4.2%;
   2. With respect to a new unit, the demonstrated average, actual EFOR of Proposer's similar existing units over the past five years is above 4.2%; or
   3. With respect to an existing unit or a new unit, the guaranteed EFOR submitted as part of the proposal is above 4.2%.
c. A proposal with a CT unit will be rejected if any of the FOF levels below is above 2.6%:
   1. The demonstrated average, actual FOF of an existing unit over the past five years is above 2.6%;
   2. With respect to a new unit, the demonstrated average, actual FOF of Proposer's similar existing units over the past five years is above 2.6%; or
   3. With respect to an existing unit or a new unit, the guaranteed FOF submitted as part of the proposal is above 2.6%.
d. The Availability, EFOR, and FOF to be reflected in the economic analysis of a proposal that has not been rejected for the reasons set forth above shall be the "worse of" the actual average Availability, EFOR, and FOF levels, or the levels guaranteed in the proposal.

ii. Heat Rate Levels

Proposer must guarantee that the generating unit will consistently achieve the heat rate levels reflected in the proposal and must provide to FPL the results of annual heat rate tests. FPL shall have the right to require a heat rate test at any time, at its sole discretion. If the generating unit fails to achieve the heat rate levels reflected in the proposal, liquidated damages in the form of a heat rate adjustment payment will be due from the Proposer. In addition, in the event of a chronic heat rate failure, the Proposer will be in default, subject to a 120 day cure period. If not cured, FPL may terminate the Purchase Agreement and collect damages, all as prescribed in the Purchase Agreement.

iii. Capacity Payment

Proposer must guarantee that the peak capacity levels reflected in the proposal will be achieved and, on an annual basis, will provide to FPL the results of peak capacity tests. Failure to achieve such peak capacity levels will result in economic penalties as described below. In addition, if the Capacity Billing Factor is below 64%, the Proposer will be in default and will have 120 days to cure. If not cured, FPL may terminate the Purchase Agreement and collect damages.

a. Capacity payments shall be made on a sliding scale, based upon Capacity Billing Factor ("CBF") over a rolling 12-month period:
   1. if the CBF is less than 64%, there is no capacity payment;
   2. if the CBF is greater than 94%, then the full capacity payment will be received;
b. between 64% and 94%, the Proposer will forfeit 2% of capacity payment for each 1% that CBF is below 94%;
c. Proposer will be entitled to a capacity bonus of 0.5% of capacity payment for each 1% that CBF is above 96% in any month;
d. Failure to maintain a CBF of 64% or greater is an event of default, and FPL can terminate the purchase agreement and collect damages.

iv. Pipeline Quality Gas

Proposed generating units that utilize natural gas must (i) be designed to handle the expected range of fuels from its source(s). However, all specified unit performance values provided by the Proposer shall be based on the "Average Fuel Analysis" specifications as presented in RFP Form # 4 in Appendix C, (ii) satisfy the operating characteristics specified in the proposal, and (iii) maintain compliance with the conditions of all permits and authorizations.

v. Compliance with Changes in Laws

Notwithstanding any change in law, during the Proposal Term the Proposer will be solely responsible for taking all actions necessary to continue to deliver reliably to FPL the firm capacity and energy offered in the proposal, in a manner that is in compliance with all applicable laws, regulations, ordinances, licenses, permits, and other regulatory approvals (including compliance with all applicable environmental law).

4. Project Execution

The Proposer will be solely and completely responsible for ensuring that the implementation of any and all parts of the proposal is carried out in full compliance with any changes, modifications, or additions to laws, regulations, ordinances, licenses, permits, and other regulatory approvals (including environmental) that affect the proposal. FPL shall not bear any price or cost risk associated with any such changes, modifications, or additions, required by regulation or legislation in existence or enacted prior to the date of the proposal.

5. Effect of FPSC Denial of Authorization for FPL Cost Recovery

i. FPL would only agree to enter into a Purchase Agreement on the basis of Rule 25.22-082(15), Florida Administrative Code, which States:

   "*If the Commission approves a purchase power agreement as a result of the RFP, the public utility shall be authorized to recover the prudently incurred costs of the agreement through the public utility's capacity, fuel and purchased power cost recovery clauses absent evidence of fraud, mistake, or similar grounds sufficient to disturb the finality of the approval under governing law.*"

ii. The selected Proposer must agree that if, at any time during the Proposal Term, FPL fails to obtain, or is denied, the authorization of the FPSC (or that of any other applicable legislative, administrative, judicial or regulatory body which now has, or in the future may have, jurisdiction over FPL's rates and charges) to recover from its customers all of the payments required to be made to the selected Proposer by FPL under such Purchase Agreement (or any subsequent amendment thereto), FPL may, in FPL's sole discretion, adjust the payments made under such Purchase Agreement to the amount(s) which FPL is authorized to recover from its customers.

iii. In the event that FPL so adjusts the payments to which the selected Proposer is otherwise entitled to under the Purchase Agreement, then the selected Proposer may, at its sole option, terminate such Purchase Agreement upon 180 days' notice to FPL. If such a determination of disallowance is ultimately reversed and such payments previously disallowed are found to be recoverable, FPL shall pay all withheld payments.

iv. The selected Proposer also acknowledges that any amounts initially received by FPL from its customers, but for which recovery is subsequently disallowed and which amounts are charged back to FPL, may be offset or credited against subsequent payments to be made by FPL to the selected Proposer under the Purchase Agreement.

v. If at any time FPL receives notice that the FPSC or any other legislative, administrative, judicial, or regulatory entity seeks or will seek to prevent full recovery by FPL from its customers of all payments required to be paid by FPL under the terms of the Purchase Agreement, then FPL shall, within 30 days of its receipt of such notice, give notice thereof to the selected Proposer. FPL shall use reasonable efforts to defend and uphold the validity of the Purchase Agreement and its right to recover from its customers all payments required to be made by FPL under the terms of such Purchase Agreement, and will cooperate in any effort by the selected Proposer to intervene in any proceeding that challenges the validity of the Purchase Agreement or the right of FPL to recover from its customers all payments required under the Purchase Agreement, and to defend such validity and such right to recover costs.

6. Conditions Precedent

The selected Proposer must agree that, pursuant to an executed Purchase Agreement, the obligations of the Proposer to generate, deliver, and sell to FPL firm capacity and energy, and the obligations of FPL to accept delivery of, purchase and pay for such firm capacity and energy, shall be subject to the satisfaction of the following conditions precedent:

i. The FPSC shall have issued a final Determination of Need (if applicable) with respect to the Purchase Agreement and a final order approving such agreement, which order includes a finding that FPL is authorized to recover from its customers all payments for firm capacity and energy purchased under the agreement, and which order is no longer subject to appeal.

ii. The Federal Energy Regulatory Commission ("FERC") and any other governmental authority having jurisdiction over such Purchase Agreement, or over either FPL or the selected Proposer, shall have issued final orders approving such agreement authorizing the selected Proposer to make the sale and authorizing FPL, with conditions acceptable to FPL at its sole discretion, to make the purchase of such firm capacity and energy, and which orders are no longer subject to appeal.

iii. Execution by the Proposer of an (i) engineering, procurement, and construction agreement, and (ii) operation and maintenance agreement by specified dates (as applicable to the nature of the proposal).
iv. Receipt by Proposer of all necessary permits.
v. Successful execution by Proposer of long-term financing (for a New Unit only).
vi. Execution by Proposer of transmission interconnection agreements.
vii. Implementation by Proposer of adequate insurance coverage.
viii. Execution by Proposer of adequate fuel supply and delivery contracts.

7. FIN 46R Compliance

Certain accounting rules now in effect, or as they might be amended or interpreted in the future, may require that the selected Proposer under the PPA or tolling contract be consolidated into the financial statements of FPL. Within ten business days after being selected to supply firm capacity and energy to FPL, the selected Proposer must deliver to FPL an analysis, with supporting information, evaluating whether or not FPL would be required to consolidate the selected Proposer under the provisions of Financial Accounting Standards Board Interpretation No. 46 (Revised December 2003) (FIN 46R).

The selected Proposer who enters into a contract with FPL under this RFP must also agree to comply with terms to be included in the Purchase Agreement that specify requirements for FPL's ongoing compliance with FIN 46R. Failure of Proposer to provide the required certification, or if at any time Proposer becomes a VIE and FPL becomes the Primary Beneficiary, shall constitute an event of default under the Purchase Agreement.

8. Completion and Performance Security; Step in Rights; Security Interest

i. For all proposals with respect to a new unit or existing unit, a Proposer selected to enter into a Purchase Agreement shall provide Completion Security and Performance Security (in the amounts set forth in Table 1 – New Unit; and Table 2 – Existing Unit, below).

Table 1
Security Milestone Schedule - New Unit

Event	Security Amount	Security Type
Execution of Purchase Agreement	$20,000/MW	Completion Security
FPSC and FERC Authorization Received	$185,000/MW	Completion Security
Commercial Operation	$200,000/MW	Performance Security

Table 2
Security Milestone Schedule - Existing Unit

Event	Security Amount	Security Type
Execution of Purchase Agreement	$20,000/MW	Completion Security
FPSC and FERC Authorization Received	$200,000/MW	Performance Security

ii. Completion Security secures (i) the Proposer's obligation to negotiate a Purchase Agreement in good faith (ii) with respect to a new unit, a Proposer's obligations to satisfy certain project milestones and deliver firm capacity and energy by a June 1, 2019 in-service date, and (ii) for damages incurred by FPL related to an early termination event.

iii. Performance Security secures (i) the Proposer's performance obligations from June 1, 2019 (the "In-Service Date") through the Proposal Term, and (ii) damages incurred by FPL related to an early termination event.

iv. With respect to a new unit during the construction phase, the Proposer must provide evidence, satisfactory to FPL in all respects, that the project milestones reflected in the Purchase Agreement are being achieved (*i.e.*, execution of definitive EPC and O&M Agreements, Start of Construction and Commercial Operations). If the Proposer fails to satisfy such project milestones, FPL may, in its sole discretion, be paid delay liquidated damages and/or terminate the Purchase Agreement.

v. Form of Security:

a. Completion Security may be provided via a combination of cash or letter of credit issued in a form and by an Eligible LC Bank ("LOC"), in each case acceptable to FPL in its sole discretion. "Eligible LC Bank" means either a U.S. commercial bank, or a foreign bank issuing a LOC through its U.S. branch, and such bank must have a Credit Rating of at least: (a) "A-, with a stable designation" from S&P and "A3, with a stable designation" from Moody's, if such bank is rated by both S&P and Moody's; or (b) "A-, with a stable designation" from S&P or "A3, with a stable designation" from Moody's, if such bank is rated by either S&P or Moody's, but not both, even if such bank was rated by both S&P and Moody's as of the date of issuance of the LOC but ceases to be rated by either, but not both of those ratings agencies.

b. FPL may consider on a case-by-case basis accepting a guaranty in a form to be provided by FPL from a "Qualified Guarantor" acceptable to FPL and based on such Qualified Guarantor's credit quality and tangible net worth in accordance with Table 3 below.

Table 3

Qualified Guarantor

A credit limit may be calculated for each Proposer or Qualified Guarantor based on the entity's unsecured debt rating and tangible net worth (the "Credit Limit") as follows:

Unsecured Debt Rating	% of Tangible Net Worth
AAA+/Aaal to AA-/Aa3	20%
A+/A1 to A-/A3	15%
BBB+/Baal to BBB-/Baa3	10%
BB+/Bal and below or unrated	0%

Performance Security in excess of the Credit Limit shall be in the form of cash in U.S. Dollars or an LOC. The Credit Limit shall be recalculated and the form of Performance Security may be adjusted quarterly, in FPL's sole discretion, based on the Proposer's or Qualified Guarantor's most recent financial statements.

Definitions
"Credit Limit" means the maximum credit exposure FPL will accept from a Qualified Guarantor in the form of a guarantee.

"Qualified Guarantor" means an entity which at the time it is to provide a guaranty has (i) (A) a credit rating equal to or greater than the Ratings Limit, and (B) a consolidated net worth of at least $1,000,000,000; or (ii) is acceptable to FPL in its sole discretion as having a verifiable creditworthiness and net worth sufficient to secure a Qualified Guarantor's obligations pursuant to a guaranty.

"Ratings Limit" means with respect to Proposer or any Qualified Guarantor, a long-term credit rating (corporate or long-term senior unsecured debt) (a) "Baa3" or higher by Moody's, or (b) "BBB-" or higher by S&P, or (iii) if rated by Moody's and S&P, both (i) and (ii).

"Tangible Net Worth" means the net worth per most recent quarterly financial statements of a Qualified Guarantor providing credit support less goodwill and intangible assets.

vi. Upon the failure of a Proposer to satisfy any project milestone, or upon an event of default by Proposer and failure by Proposer to cure such default within the cure period provided, FPL (or its designee) shall have the right, but not the obligation, to enter upon and complete the licensing, permitting, construction, start-up, testing and commissioning, or operate and maintain the generating unit, as applicable, as agent for the Proposer. FPL's step-in right shall continue until the earlier of: (i) Proposer demonstrates to FPL's satisfaction that cause of the failure or default has been remedied, (ii) FPL elects, in its sole discretions, to discontinue exercising its step-in rights, or (iii) expiration or termination of the Purchase Agreement.

vii. As additional security for Proposer's performance obligations, Proposer shall execute, deliver to FPL, and record a Mortgage and Security Agreement to granting to FPL a fully perfected, subordinated security interest and mortgage lien in any and all real and personal property, contractual rights or other rights the Proposer holds with respect to the development, procurement, construction, operation, and maintenance of the generating unit.

9. Assignment; Right of First Refusal

i. The Proposer must agree that the Purchase Agreement may not be assigned in whole or in part without the express written consent of FPL at FPL's sole discretion. Any direct or indirect change of control of Proposer (whether voluntary or by operation of Law) shall be deemed an assignment and shall require the prior express written consent of FPL at FPL's sole discretion.

ii. During the Proposal Term, FPL shall have a right of first refusal with respect to any sale of the generating unit or facility that produces the capacity and energy that is the subject of the PPA.

Section V. Overview of the Evaluation Process

1. General Evaluation Concepts

i. Proposer Exceptions.

FPL will consider proposals that contain exceptions to the general terms and conditions of the RFP. However, **FPL will not accept any exceptions to the Minimum Requirements for Proposals or the Minimum Requirements Pursuant to Purchase Agreement.**

If a Proposer identifies exceptions, the exceptions must be explained in writing as part of the proposal using Form # 9 presented in Appendix C. For each exception, the Proposer must fully explain in writing the condition, requirement, or facet of the RFP to which the Proposer takes exception and provide the replacement language proposed.

Inclusion of exception information with a proposal will be used to compare proposals to one another and will facilitate potential negotiations by allowing FPL to evaluate the specific core issues of the exceptions, rather than addressing generic or conceptual comments. A more detailed discussion of the non-price evaluation is provided in Appendix D. FPL reserves the right to request from a Proposer whether, or to what extent, FPL's contemplated rejection of a particular exception would affect the pricing of the proposal.

If a Proposer fails to state exceptions and pose alternative language to the material terms set forth in the RFP, FPL shall assume that a Proposer has no objection to such terms and conditions.

ii. **Proposer Questions and Communications**

Proposers are to follow all instructions contained in this RFP and provide all information requested in the RFP and on the forms presented and discussed in Appendix C of this document. Proposers also are expected to provide supporting documentation, and answer any follow-up questions from FPL, as requested.

Proposers are encouraged, up to the Cutoff Date for RFP Questions, to contact the FPL Contact Person with questions to ensure complete and accurate proposals. Following the RFP issuance date, all questions will be recorded. FPL will post questions and answers on FPL's RFP website. All questions and answers from the Pre-Bid Workshop, and any subsequent questions posed to FPL and answers to these questions, will be posted on this website for the benefit of all Proposers.

iii. **Fuel Plan for Evaluation**

FPL will evaluate the generator-specific fuel costs of each natural gas-based proposal based on the designated FPL Fossil Fuel Price Forecast (unless a Proposer directs FPL to use Proposer's own firm, guaranteed fuel price forecast, which shall be included in the proposal). FPL system fuel cost impacts for all proposals will also be based on the above-mentioned FPL forecast. FPL's forecast will be posted on the RFP website once the RFP document has been issued.

A specific fuel plan, including Proposer's fuel transportation cost (for Non-Tolling proposals) or FPL's projection of the gas transportation cost (for natural gas Tolling proposals), will be developed by FPL for each candidate portfolio based on the size, location, and fuel requirements of the individual units included in the candidate portfolio. This will allow FPL to capture the unique fuel cost attributes offered by certain asset combinations. The portfolio-specific fuel plan will be used to conduct the detailed economic evaluation.

1. Non-Tolling Proposals

   Non-tolling proposals must be accompanied by a complete Fuel Plan. The Fuel Plan must designate the fuel type, the intended fuel source, and transportation method to be used. For proposals relying on natural gas, the Fuel Plan must provide the level of firm gas transportation that is appropriate for the technology proposed. The Fuel Plan must be accompanied by evidence of feasibility (letter of intent or other indicative planning documents) that identify the required volume, pressure, and pipeline infrastructure upgrades that will be accomplished to operate the proposed unit(s) at capacity. The proposed pricing for non-Tolling proposals must reflect firm fuel transportation costs for the entire Proposal Term. FPL will evaluate non-Tolling proposals using FPL's fuel price forecast unless the Proposer specifies and guarantees a different set of future fuel prices to be applied to such proposal.

2. Natural Gas Tolling Proposals (For specific units only - not for system sales)

   Natural Gas Tolling proposals will be evaluated using the data outlined in the designated FPL Fossil Fuel Price Forecast, as modified for the specific fuel plan of the candidate portfolio(s). FPL will not consider tolling agreements for fuels other than natural gas.

   As a part of a natural gas tolling arrangement, FPL will be required to negotiate and commit to a Firm Transportation Agreement to support the needs of the project. Selected Proposers entering into a Natural Gas Tolling agreement will be required to provide an appropriate level of additional security to cover the costs that may arise from a Proposer-default to protect FPL's customers. This will be a part of the definitive agreements that comprise the Tolling Agreement.

FPL will evaluate all natural gas tolling proposals and the NPGU utilizing FPL's forecast(s) of future fuel commodity prices.

2. The Evaluation Process

The objective of the RFP is to solicit proposals that allow FPL to assess the best eligible generating alternatives that meet the RFP's capacity requirement in the most economic, cost-effective, and reliable manner for FPL's customers. It is anticipated that FPL will receive a variety of proposals that may vary in length of term, siting, capacity, price, fuel, and other pertinent characteristics. In addition to the variations that may be presented within individual proposals, there may be a need to combine multiple proposals to develop portfolios that meet the RFP capacity need requirements.

FPL will employ an evaluation methodology that will anticipate responses that offer a wide range of individual characteristics and can evaluate the costs and benefits offered by combining various proposals into unique portfolios of generating alternatives that address FPL's resource needs beginning in the year 2019. Therefore, eligible proposals that pass initial screening and individual economic ranking (if applicable), but do not individually meet the full resource need requirement for 2019, will be evaluated in portfolios that combine them with other proposals to meet these capacity needs. FPL will then develop multi-year resource plans that incorporate proposals that individually meet the 2019 resource need, portfolios of smaller proposals, and/or the NPGU.

FPL's evaluation will examine these portfolios and resource plans from both economic and non-economic perspectives. In regard to the economic analyses, FPL typically conducts economic analyses of resource plans using a levelized system average electric rate minimization (*i.e.*, a Rate Impact Measure) approach. However, because FPL is soliciting only generation resources in this capacity RFP, the amount of projected DSM will be the same for each of these resource plans. Therefore, FPL will be comparing portfolios and resource plans based on a Cumulative Present Value of Revenue Requirements (CPVRR) approach. This is because in analyses in which DSM values will not change: (i) a levelized system average electric rate approach and a CPVRR approach will yield identical rankings for the resource plans being evaluated, and (ii) the CPVRR approach is simpler to calculate. In regard to non-economic analyses, several different perspectives will be taken.

Ultimately, FPL's objective is, after considering both economic and non-economic perspectives, to identify the best option(s) for FPL's customers with which to meet FPL's capacity needs beginning in 2019. FPL's evaluation methodology, including a description of the criteria to be used to evaluate price and non-price attributes, is discussed in detail in Appendix D.

Section VI - Detailed Information Regarding FPL's Capacity Needs and NPGU

A. FPL's Capacity Need

The projected generation capacity resource need values described below represent an update from the information presented in FPL's 2014 Ten-Year Power Plant Site Plan (Site Plan), a copy of which is attached to this RFP as Appendix A. This new capacity need projection is based on a number of factors including updated forecasts from those used in FPL's previous resource planning work that led to FPL's 2014 Site Plan. Key changes to these forecasts are discussed in Appendix E. FPL's projected capacity needs are potentially subject to further change as FPL's 2015 resource planning work continues.

FPL's projected capacity need in 2019, based on exactly meeting both the 10% generation-only reserve margin (GRM) planning criterion and the 20% total reserve margin planning criterion is 1,052 MW by June 1, 2019.

B. FPL's NPGU

Rule 25-22.082, Florida Administrative Code, requires that specific information about FPL's "next planned generating unit" (NPGU) be included in an RFP seeking firm capacity.

FPL's NPGU is a CC unit based on 3 combustion turbines in combined cycle form with 3 heat recovery system generators and a single steam turbine generator (a 3x1 G configuration). The NPGU CC would add approximately 1,622 MW (Summer).

FPL has now identified a CC unit at FPL's Okeechobee Clean Energy Center site ("OCEC Unit 1") to be installed by June 1, 2019 as the NPGU in accordance with the requirements of Rule 25-22.082(5)(a), Florida Administrative Code. The eligible proposals submitted in response to this RFP will be evaluated against this NPGU and against all other proposals received in response to this RFP.

1. **Required Information**

   FPL is providing a technical description of its NPGU with the information that follows. This technical description for the unit complies with the requirements of Rule 25-22.082 (5)(a).

2. **Tables**

   The technical information required by Rule 25-22.082 (5) (a) is presented in Tables VI.B - 1, VI.B - 2, and VI.B - 3 for FPL's NPGU.

Table VI.B – 1

Next Planned Generating Unit Data – Okeechobee Clean Energy Center (Combined Cycle)

The following data represent FPL's current estimates for this 2019 capacity addition. These planning estimates are subject to further refinement in regard to site-specific costs, detailed engineering, or vendor quotes. FPL reserves the right to modify the construction costs and/or performance parameters for this unit. If FPL exercises this option, it will do so concurrent with publication of a Short List. In that case, FPL would then inform the Short List Proposers (if any) of its intent and permit such Short List Proposers to revise their proposals.

1. A three-on-one combined cycle generating unit to be located at the Okeechobee Clean Energy Center (OCEC) in Okeechobee County, Florida.
2. Planned size is 1,622 MW (Summer rating).
3. Commercial operation for the facility is June 1, 2019.
4. The primary fuel is natural gas. Ultra low sulfur light (distillate) oil will be the backup fuel type.
5. The estimated total direct cost (without AFUDC) is $ 1,083.4 million (in 2019$). This value includes the cost of generation, transmission interconnection, and transmission integration.
6. The estimated annual levelized capital (generation, plus transmission interconnection, and transmission integration) revenue requirement with AFUDC is $136.9 million over 30 years.
7. The estimated annual value of deferral with AFUDC of this unit is $5.75/kW-year in 2019$ (excludes variable O&M, fixed O&M, and capital replacement).
8. The estimated fixed O&M, capital replacement, and variable O&M annual costs are presented in Table III.B - 2.
9. The estimated fuel cost in 2019 for the NPGU is currently forecast to be $4.69/MMBTU. Firm gas transportation for the unit will be provided from the Sabal Trail/Florida Southeast Connection (FSC) pipeline. These costs are considered sunk and will not be included in the economic analysis. A gas pipeline lateral is needed between FSC and the Okeechobee site and will be built by FSC. The costs for this lateral will be recovered through an adjustment to the rate over 25 years. This adjustment to the annual transportation rate, in $/MMBTU, is shown in Table III.B-3 and will be included in the economic evaluation of the Okeechobee Clean Energy Center. See Note 1.
10. The following are the estimates for:

Planned Outage Factor	See Table III.B - 4 and Note 2
Forced Outage Rate	See Table III.B - 4 and Note 2
Heat Rate at maximum capacity at 100% (Base Operational Mode)	6,293 Btu/kWh @75F (HHV)
Minimum load	400 MW
Ramp Rate	120 MW/min

11. The estimated transmission interconnection and integration costs associated with this unit are $52.0 million (without AFUDC in 2019 $) and are included in the cost estimate in item 5 above.
12. Air, water discharge, and other permits will be required for this unit. It is FPL's plan to comply with all air and water quality standards of the Local, State, and Federal governments.
13. The major financial assumptions in the development of these numbers were:

Capital replacement escalation for the OCEC unit, based on contract (approx.)	2.0%
General capital escalation for other than OCEC	3.0%
Escalation for O&M	2.5%
Fuel escalation	Varies by year. See Note 1
Capital Structure	40.38 % debt @ 5.05 % 59.62 % equity @ 10.5 %

Table VI.B-2

Next Planned Generating Unit Data - OCEC

Year	Estimated Fixed O&M Costs ($Millions)	Estimated Variable O&M Costs * ($Millions)	Estimated Capital Replacement Costs ($Millions)
2019	3.3	3.2	0.0
2020	4.7	3.2	19.5
2021	3.6	3.3	0.1
2022	6.9	3.3	40.0
2023	4.0	3.4	23.9

Notes for:
Next Planned Generating Unit Data – Okeechobee Clean Energy Center

1. For the economic evaluation of capacity options in this RFP, both for proposals received in response to this RFP and FPL's NPGU, FPL will use the designated FPL fuel cost forecast which will be provided on the RFP website.
2. The projected outage hour estimates for FPL's self-build options represent arithmetic averages of expected outage hours over the 30-year life of the unit period and do not represent "new & clean" unit values. An average capacity factor of 80% for the unit as a whole was used in making these projections. Maintenance outage hours were not included in these projections.

   Using these outage hour values, FPL projects the following values for both the Base and Peak Firing operational modes:

POF	2.2%
FOR	1.1%
Availability	96.7%

APPENDIX A

2014 Ten Year Site Plan

Ten Year Power Plant Site Plan 2014 – 2023

FPL

Ten Year Power Plant Site Plan

2014-2023

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten Year Power Plant Site Plan (Site Plan). This Site Plan should include an estimate of the utility's future electric power generating needs, a projection of how these estimated generating needs could be met, and disclosure of information pertaining to the utility's preferred and potential power plant sites. The information contained in this Site Plan is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (F.A.C.).

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains uncertain forecasts and tentative planning information. Forecasts evolve, and all planning information is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings, at the appropriate time.

This Site Plan document is based on Florida Power & Light Company's (FPL) integrated resource planning (IRP) analyses that were carried out in 2013 and that were on-going in the first Quarter of 2014. The forecasted information presented in this plan addresses the years 2014 through 2023.
This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, based on FPL's IRP work in 2013 and early 2014. This chapter also discusses a number of issues that may change the resource plan presented in this Site Plan. Furthermore, this chapter briefly discusses the status of FPL's DSM planning efforts, as well as FPL's, renewable energy efforts, transmission planning additions, and fuel cost forecasts.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as Preferred and Potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional information that is included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2014 Ten Year Power Plant Site Plan (Site Plan) presents FPL's current plans to augment and enhance its electric generation capability (owned or purchased) as part of its efforts to meet its projected incremental resource needs for the 2014 - 2023 time period. By design, the primary focus of this document is on supply side additions; i.e., electric generation capability and the sites for these additions. The supply side additions discussed in this document are resources projected to be needed, based on FPL's load forecast, after accounting for FPL's demand side management (DSM) resource additions. In 2014, new DSM Goals for FPL for the time period 2015 through 2024 will be set by the Florida Public Service Commission (FPSC). At almost the same time FPL is filing this 2014 Site Plan, FPL will also be filing its proposed DSM Goals with the FPSC. Consequently, the level of DSM additions reflected in the 2014 Site Plan is consistent with FPL's proposed DSM Goals. The proposed level of DSM is discussed further below and in Chapter III.

FPL's load forecast accounts for a significant amount of efficiency that results from federal and state energy efficiency codes and standards. The projected impacts of these codes and standards are directly accounted for in FPL's load forecast as discussed below and in Chapter II.

The resource plan that is presented in FPL's 2014 Site Plan contains four key similarities to the resource plan presented in FPL's 2013 Site Plan. However, there are several factors that have contributed to differences between the resource plan presented in the 2014 Site Plan and the resource plan that was previously presented in FPL's 2013 Site Plan. Additional factors will continue to influence FPL's on-going resource planning work and could result in changes in the resource plan presented in this document. A brief discussion of these similarities and factors is provided below. Additional information regarding these topics is presented in Chapter III.

I. Similarities Between the Current Resource Plan and the Resource Plan Previously Presented in FPL's 2013 Site Plan:

There are four key similarities between the current resource plan presented in this document and the resource plan presented in the 2013 Site Plan.

Similarity # 1: Modernizations of Existing Power Plant Sites.

The modernization of FPL's Cape Canaveral plant site was completed on time in 2013 and the modernization of FPL's existing Riviera Beach plant site is scheduled to be completed on/near the April 1, 2014 date this 2014 Site Plan is to be filed. In addition, the modernization of FPL's existing Port Everglades plant site is underway and is projected to be completed in 2016.

Similarity # 2: FPL continues to pursue additional nuclear energy generation to significantly (i) reduce its use of fossil fuels, (ii) lower system fuel costs, (iii) lower system air emissions, and (iv) provide a valuable hedge against future increases in fuel costs and environmental compliance costs.

In 2013 FPL successfully completed its capacity uprate projects at its four existing nuclear units ; Turkey Point Units 3 & 4 and St. Lucie Units 1 & 2. The nuclear uprate project added about 520 MW of additional nuclear capacity to FPL's system which was about 30% more additional nuclear capacity than was originally projected when the project began. FPL's customers are already benefiting from lower fuel costs and reduced system air emissions provided by this additional nuclear capacity.

FPL is also continuing its work to obtain all of the licenses, permits, and approvals that will be necessary to construct and operate two new nuclear units at its Turkey Point site in the future. The earliest deployment dates for these two new units remain 2022 and 2023, respectively, and this Site Plan projects the two new nuclear units going in-service in those years.

Similarity #3: FPL is projected to serve Vero Beach's electrical load.

An agreement to this effect was reached between Vero Beach and FPL on February 19, 2013, and a referendum was held on March 12, 2013 that resulted in a majority of Vero Beach voters approving the agreement. FPL's current load forecast projects that FPL will begin serving Vero Beach's load in January 2015.

Similarity #4: Specific generating units are projected to be retired and/or converted to synchronous condenser operation.

In the last two years, FPL has retired a number of older, less efficient generating units including: Sanford Unit 3, Cutler Units 5 & 6, Cape Canaveral Units 1 & 2, Riviera Beach Units 3 & 4, and Port Everglades Units 1 – 4. In addition, Turkey Point Unit 2 has been converted to operate in synchronous condenser mode to provide voltage support for the transmission system in Southeastern Florida.

This trend is projected to continue. Putnam Units 1 & 2 are now projected to be retired by the end of 2014. And, similar to the earlier conversion of Turkey Point Unit 2, FPL projects that Turkey Point Unit 1 will be converted to run in synchronous condenser mode starting in 2016. In addition, for planning purposes, FPL is projecting that all of its existing gas turbines (GTs) at its two Broward County sites will be retired by the end of 2018 and that 5 new combustion turbines (CTs) will be installed at FPL's Lauderdale plant site also by the end of 2018. This projection is further discussed later in this executive summary and in Chapter III.

II. Factors Influencing FPL's Resource Planning Work Which Have Impacted, or Which Could Impact, FPL's Resource Plan:

There are a number of factors that influence FPL's resource planning work. Eight (8) of these are briefly discussed below and are discussed again in Chapters II and/or III.

Two of these factors are on-going system concerns that FPL has considered in its resource planning work for a number of years. These two on-going system concerns are: (1) maintaining/enhancing fuel diversity in the FPL system, and (2) maintaining a balance between load and generating capacity in Southeastern Florida, particularly in Miami-Dade and Broward Counties.

The third and fourth factors that will be discussed are factors that directly impacted the resource plan presented in this document because they affect FPL's forecast of its future load and its future firm load. The third factor is the impact of federal and state energy efficiency codes and standards on FPL's future loads. The impact of these codes and standards has been incorporated into FPL's current load forecast. The magnitude of efficiency that is being delivered to FPL's customers through these codes and standards is significant. For example, by the year 2023 (the last year addressed in this Site Plan), FPL's Summer peak is projected to be lower by approximately 3,477 MW compared to what the projected load would have been without the codes and standards based on cumulative savings beginning in 2005. This represents a decrease of approximately 12% in what the forecasted Summer peak load for 2023 would have been without the codes and standards. Likewise, FPL's forecasted net energy for load (NEL) in the year 2023 is projected to be approximately 9,991 GWh lower compared to what the projected NEL would have been without the efficiency codes and standards based on cumulative savings beginning in 2005. This represents a decrease of approximately 7% from what the forecasted NEL for 2023 would have been without the codes and standards.

There are two significant impacts from these codes and standards. The first impact is to substantially lower FPL's forecasted peak load and NEL. The second impact is that the codes and standards lower the potential for future MW and GWh reductions from FPL's DSM programs that address the specific appliances and equipment impacted by the codes and standards. Thus, significant energy efficiency regarding this equipment will be delivered to FPL's customers through codes and standards, thus precluding the potential for FPL to pursue these same efficiency gains through utility DSM programs.

The fourth factor is a projected decline in the cost-effectiveness of a number of utility DSM measures due to reasons that are beneficial overall for FPL's customers. Compared to 2009 (when DSM Goals were last set): (i) forecasted fuel costs have dropped by 50%, thus lowering the potential benefits from DSM kwh reductions; (ii) projected compliance costs for carbon dioxide (CO_2), have not only been significantly lowered, but their forecasted start date has been delayed by almost a decade, thus again lowering the potential benefits from DSM kwh reductions; and, (iii) FPL's generating system, due to the retirement of older, less efficient generators and replacement with highly efficient generators, plus additional nuclear capacity, has gotten more fuel-efficient, thus lowering fuel-related costs that would otherwise represent potential benefits for DSM kwh reductions. These factors are benefitting FPL's customers through lower electric rates, but they also lower the potential economic benefits that otherwise could be offered by DSM. When combined with the previously discussed fact that codes and standards have reduced the potential for efficiency gains in regard to appliance and equipment addressed by these codes and standards, the result is that FPL is logically projecting a lower contribution from utility DSM in the near-term. That lower contribution is accounted for in the 2014 Site Plan. These factors are discussed in detail in the filing FPL is making in its DSM Goals proceeding.

The fifth factor is the need to take measures to limit FPL's projected increasing dependence upon DSM resources to maintain system reliability. This factor has been previously discussed in FPL's 2011, 2012, and 2013 Site Plans. In these previous Site Plans, FPL has discussed this projection of increasing dependence upon DSM resources using a new type of reserve margin projection as an indicator: a "generation-only reserve margin" or "GRM".

The GRM projections from the 2011, 2012, and 2013 Site Plans consistently showed that these values were projected to significantly decrease over the 10-year reporting period of the Site Plans, declining to single-digit values in the latter years of the reporting periods. These projections indicated a steadily growing dependence on DSM resources to maintain system reliability. FPL's analyses show that system reliability risk increases, particularly from a system operations perspective, as dependence on DSM resources increases to a point where DSM resources account for more than half of FPL's 20% total reserve margin criterion value. Therefore, FPL is implementing a new reliability criterion of a 10% GRM in its resource planning work to complement its other two reliability criteria: a 20% total reserve margin criterion for Summer and Winter, and an annual 0.1 day/year loss-of-load-probability (LOLP) criterion. FPL is implementing the GRM criterion so that FPL's resource plans will begin to meet this criterion in the year 2019. A further discussion of the GRM criterion is presented in Chapter III.

There are additional factors that did not impact FPL's resource plan presented in this document, but which could result in future changes to this resource plan. For example, a sixth factor is the project schedule for the Turkey Point Units 6 & 7 nuclear units. At the time the 2014 Site Plan is being finalized, the Nuclear Regulatory Commission (NRC) has not provided a schedule for its review of FPL's Combined Operating License Application (COLA). Once the NRC's COLA review schedule is available, FPL will review the overall schedule for the Turkey Point Units 6 & 7 project. FPL's review will also consider the impacts of the recently amended nuclear cost recovery clause (NCRC) statute and the ongoing feasibility analyses that are part of Florida Nuclear Cost Recovery process.

The seventh factor is environmental regulation. As developments occur in regard to either new environmental regulations, and/or in how environmental regulations are interpreted and applied, the potential exists for such developments to affect FPL's resource plan that is presented in this document. For example, FPL is aware of potential impacts to generating units of recent EPA changes to the National Ambient Air Quality Standards that include shorter duration 1-hour standards for nitrogen dioxide (NO_2) and sulfur dioxide (SO_2). As a consequence, FPL filed in mid-2013 for FPSC approval to recover costs through the environmental cost recovery clause for removing all of its existing gas turbines (GTs) and partially replacing that peaking unit capacity with new combustion turbines (CTs). Although FPL withdrew its filing in December 2013 pending further analyses including on-site monitoring, FPL believes that the results of the monitoring and analyses will require that the Broward GTs be replaced. Therefore, FPL is currently projecting the retirement of all GTs in Broward County; i.e., at its existing Lauderdale and Port Everglades plant sites (a decrease in generating capacity of 1,260 MW Summer), and the installation of 5 new 201 MW CTs at its existing Lauderdale plant site (an increase of 1,005 MW Summer).

The eighth factor that will be discussed is the possibility of the establishment of a Florida standard for renewable energy or clean energy. Although no such legislation has been enacted to-date, Renewable Portfolio Standards, or Clean Energy Portfolio Standards legislation, or other legislative initiatives regarding renewable or clean energy contributions, may occur in the future at either the state or national level. If such legislation is enacted, FPL would then determine what steps need to be taken to address the legislation.

Each of these factors will continue to be examined in FPL's on-going resource planning work during the rest of 2014 and in future years.

Table ES-1 presents a current projection of major changes to specific generating units and firm capacity purchases for 2014 – 2023. (Although this table does not specifically identify the impacts of projected DSM additions on FPL's resource needs and resource plan, FPL's projected DSM additions have been fully accounted for in the resource plan presented in this Site Plan.)

Table ES-1: Projected Capacity & Firm Purchase Power Changes

Year *	Projected Capacity & Firm Purchase Power Changes	Summer MW	Date	Summer Reserve Margin **
2014	Martin Unit 1 ESP - Return from ESP outage	823	March-14	
	Martin Unit 2 ESP - Temporary Outage to install ESPs	(826)	March-14	
	Turkey Point Unit 5 CT Upgrade	30	March-14	
	Sanford 5 CT Upgrade	9	September-13	
	Riviera Beach Next Generation Clean Energy Center	1,212	April-14

	Fort Myers Unit 2 CT Upgrades	18	May-15	
	Total of MW changes to Summer firm capacity:	**563**		**27.5%**
2016	UPS Replacement	(928)	December-15	
	Port Everglades Next Generation Clean Energy Center	1,237	June-16	
	Total of MW changes to Summer firm capacity:	**309**		**26.6%**
2017	Turkey Point Unit 1 synchronous condenser	(396)	October-16	
	Total of MW changes to Summer firm capacity:	**(396)**		**22.6%**
2018	OUC - Stanton PPAs	(37)	December-17	
	Vero Beach Combined Cycle [1/]	(46)	January-18	
	Total of MW changes to Summer firm capacity:	**(83)**		**20.5%**
2019	Port Everglades GT retirement	(420)	December-18	
	Lauderdale GT retirement	(840)	December-18	
	Lauderdale CT	1,005	January-19	
	SJRPP suspension of energy	(381)	April-19	
	Unsited CC	1,269	June-19	
	Total of MW changes to Summer firm capacity:	**633**		**21.6%**
2020	Unspecified Purchase	129	June-20	
	Total of MW changes to Summer firm capacity:	**129**		**20.5%**
2021	Eco-Gen PPA	180	January-21	
	Unspecified Purchase	168	June-21	
	Total of MW changes to Summer firm capacity:	**348**		**20.6%**
2022	Cape Next Generation Clean Energy Center	87	June-22	
	Turkey Point Nuclear Unit 6	1,100	June-22	
	Total of MW changes to Summer firm capacity:	**1,187**		**22.6%**
2023	Riviera Beach Next Generation Clean Energy Center	55	June-23	
	Turkey Point Nuclear Unit 7	1,100	June-23	
	Total of MW changes to Summer firm capacity:	**1,155**		**24.4%**

* Year shown reflects when the MW change begins to be accounted for in Summer reserve margin calculations. (Note that addition of MW values for each year will not yield a current cumulative value.)

** Winter Reserve Margins are typically high than Summer Reserve Margin. Winter Reserve Margin are shown on Schedule 7.2 in Chapter III.

1/ This unit will be added as part of the agreement that FPL will serve Vero Beach's electric load starting January, 2015. This unit is expected to be retired within 3 years.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 9.0 million people. FPL served an average of 4,626,934 customer accounts in thirty-five counties during 2013. These customers were served by a variety of resources including: FPL-owned fossil-fueled, renewable, and nuclear generating units, non-utility owned generation, demand side management (DSM), and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory, plus one site in Georgia (partial FPL ownership of one unit) and one site in Jacksonville, Florida (partial FPL ownership of two units). The current electrical generating facilities consist of four nuclear units, three coal units, sixteen combined cycle (CC) units, five fossil steam units, forty-eight combustion gas turbines, two simple cycle combustion turbines, and two photovoltaic facilities[1]. The locations of these eighty generating units are shown on Figure I.A.1 and in Table I.A.1.

FPL's bulk transmission system is comprised of 6,734 circuit miles of transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 589 substations in Florida.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2.

1 FPL also has one 75 MW solar thermal facility at its Martin plant site. This facility does not generate electricity as the other units mentioned above do. Instead, it produces steam that reduces the use of fossil fuel to produce steam for electricity generation.

FPL Generating Resources by Location

Location/ Map Key	Plant Name	Number of Units	Summer MW
A	Turkey Point	4	3,176
B	St. Lucie [1/]	2	1,821
C	Manatee	3	2,729
D	Fort Myers	3	1,748

Combustion Turbines				
Fort Myers	Fort Myers, FL	2	Gas/Oil	316
Total Combustion Turbines:		**2**		**316**
PV				
DeSoto [3/]	DeSoto, FL	1	Solar Energy	25
Space Coast [3/]	Brevard County, FL	1	Solar Energy	10
Total PV:		**2**		**35**
Total System Generation as of December 31, 2013 =		**80**		**24,274**
System Firm Generation as of December 31, 2013 =		**78**		**24,239**

1/ Total capability of St. Lucie 1 is 981/1,003 MW. FPL's share of St. Lucie 2 is 840/860. FPL's ownership share of St. Lucie Units 1 and 2 is 100% and 85%, respectively.
2/ Capabilities shown represent FPL's output share from each of the units (approx. 92.5% and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit. Represents FPL's ownership share: SJRPP coal: 20% of two units).
3/ The 25 MW of PV at DeSoto and the 10 MW of PV at Space Coast are considered as non-firm generating capacity and the capacity from these units has been removed from the "System Firm Generation" row at the end of the table.

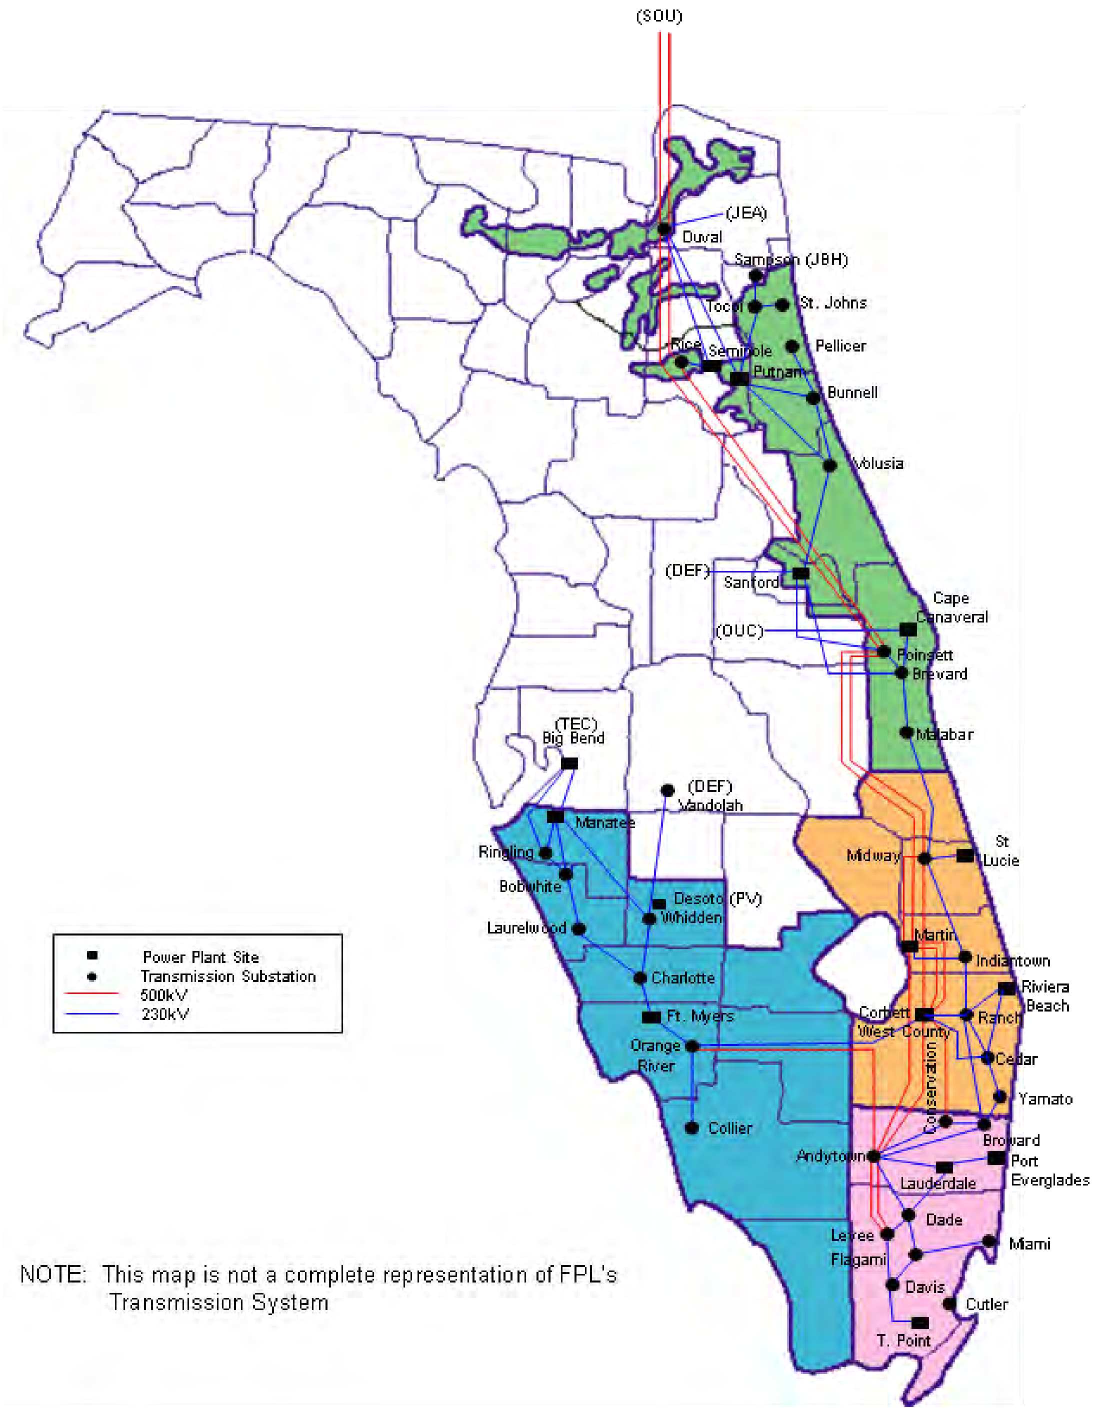

Figure I.A.2: FPL Substation and Transmission System Configuration

Description of Existing Resources

I.B Capacity and Energy Power Purchases

Firm Capacity Purchases from Qualifying Facilities (QF)

Firm capacity power purchases are an important part of FPL's resource mix. FPL currently has contracts with eight qualifying facilities; i.e., cogeneration/small power production facilities, to purchase firm capacity and energy during the 10-year reporting period of this Site Plan as shown in Table I.A.3, Table I.B.1, and Table I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source solar, wind, waste, geothermal, or other renewable resources.

Firm Capacity Purchases from Utilities

FPL has a Unit Power Sales (UPS) contract to purchase 928 MW from the Southern Company (Southern) through the end of December 2015. This capacity is being supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 375 MW (Summer) and 383 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2. However, due to Internal Revenue Service (IRS) regulations, the total amount of energy that FPL may receive from this purchase is limited. FPL currently assumes, for planning purposes, that this limit will be reached in April 2019. Once this limit is reached, FPL will be unable to receive firm capacity and energy from these purchases. (However, FPL will continue to receive firm capacity and energy from its ownership portion of the SJRPP units.)

As part of the agreement that FPL will begin serving Vero Beach's electrical needs beginning in January 2015, FPL has acquired two existing power purchase agreements totaling approximately 37 MW of coal-fired capacity. These agreements will run through the end of 2017.

These purchases are shown in Table I.A.3, Table I.B.1, and Table I.B.2. FPL also has ownership interest in the SJRPP units. The ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1.

Firm Capacity Other Purchases

FPL has two other firm capacity purchase contracts with non-QF, non-utility suppliers. These contracts with the Palm Beach Solid Waste Authority were previously listed as QFs. However, the addition of a second unit will cause both units to no longer meet the statutory definition of a QF. These contracts are therefore listed as "Other Purchases" after the current estimated in-service date of the new unit. Table I.B.1 and I.B.2 present the Summer and Winter MW, respectively, resulting from these contracts under the category heading of Other Purchases.

Non-Firm (As Available) Energy Purchases

FPL purchases non-firm (as-available) energy from several cogeneration and small power production facilities. Table I.A.3 shows the amount of energy purchased in 2013 from these facilities.

Table 1.A.3: Purchase Power Resources by Contract (as of December 31, 2013)

Firm Capacity Purchases (MW)	Location (City or County)	Fuel	Summer MW
I. Purchases from QF's: Cogeneration/Small Power Production Facilities			
Cedar Bay Generating Co.	Duval	Coal (Cogen)	250
Indiantown Cogen., LP	Martin	Coal (Cogen)	330
Broward South	Broward	Solid Waste	4
Broward North	Broward	Solid Waste	11
Palm Beach SWA - extension			40
		Total:	**635**
II. Purchases from Utilities:			
UPS from Southern Company	Various in Georgia	Coal	928
SJRPP	Jacksonville, FL	Coal	381
		Total:	**1,309**
		Total Net Firm Generating Capability:	**1,944**

Non-Firm Energy Purchases (MWH)

Project	County	Fuel	In-Service Date	Energy (MWH) Delivered to FPL in 2013
Okeelanta (known as Florida Crystals and New Hope Power Partners) *	Palm Beach	Bagasse/Wood	11/95	87,723
Broward South *	Broward	Solid Waste	9/09	90,116

5/ These unspecified purchases are short-term purchases that are included for resource planning purposes. No decision regarding such purchases is needed at this time.

I.C Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978. These programs include a number of conservation/energy efficiency and load management initiatives. FPL's DSM efforts through 2013 have resulted in a cumulative Summer peak reduction of approximately 4,753 MW at the generator and an estimated cumulative energy saving of approximately 66,782 Gigawatt-hour (GWh) at the generator. After accounting for reserve margin requirements, FPL's DSM efforts through 2013 have eliminated the need to construct the equivalent of approximately 14 new 400 MW generating units. New DSM Goals for FPL for the 2015 through 2024 time period will be set by the FPSC in the second half of 2014. DSM is discussed further in Chapter III.

1/ These ratings are peak capability.

2/ The capacity shown for the PV facility at DeSoto is considered as non-firm generating capacity and the capacity from these units has been removed from the "System Firm Generating Capacity as of December 31, 2013" row at the end of the table.

3/ Martin Unit 8 is also partially fueled by a 75 MW solar thermal facility that supplies steam when adequate sunlight is available, thus reducing fossil fuel use.

Total System Generating Capacity as of December 31, 2013 [6/] =												**25,691**	**24,274**
System Firm Generating Capacity as of December 31, 2013 [7/] =												**25,656**	**24,239**

1/ These ratings are peak capability.
2/ These ratings represent Florida Power & Light Company's share of Scherer Unit 4, adjusted for transmission losses.
3/ The capacity shown for the PV facility at Space Coast is considered as non-firm generating capacity due to the intermittent nature of the solar resource.
4/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Units 1 and 2, excluding the Jacksonville Electric Authority (JEA) share of 80%.
5/ Total capability of St. Lucie 1 is 981/1,003 MW. FPL's share of St. Lucie 2 is 840/860.FPL's ownership share of St. Lucie Units 1 and 2 is 100% and 85%, respectively, as shown above. FPL's share of the deliverable capacity from each unit is approx. 92.5% and exclude the Orlando Utilities Commission (OUC) and Florida Municipal Power Agency (FMPA) combined portion of approximately 7.44776% per unit.
6/ The Total System Generating Capacity value shown includes FPL-owned firm and non-firm generating capacity.
7/ The System Firm Generating Capacity value shown includes only firm generating capacity.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

II. A. Overview of the Load Forecasting Process

Long-term forecasts of sales, net energy for load (NEL), and peak loads are typically developed on an annual basis for resource planning work at FPL. New long-term forecasts were developed by FPL in late 2013 that replaced the previous long-term load forecasts that were used by FPL during 2013 in much of its resource planning work and which were presented in FPL's 2013 Site Plan. These new load forecasts are utilized throughout FPL's 2014 Site Plan. These forecasts are a key input to the models used to develop FPL's integrated resource plan.

The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads. Consistent with past forecasts, the primary drivers to develop these forecasts include economic conditions and weather.

The projections for the national and Florida economies are obtained from the consulting firm IHS Global Insight. Population projections are obtained from the Florida Legislature's Office of Economic and Demographic Research (EDR). These projections are developed in conjunction with the Bureau of Economic and Business Research (BEBR) of the University of Florida. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects FPL's energy sales and peak demand. Three sets of weather variables are developed and used in FPL's forecasting models:

1. Cooling degree-hours based on 72^{o} F, winter heating degree-days based on 66^{o} F, and heating degree-days based on 45^{o} F are used to forecast energy sales.
2. The maximum temperature on the peak day, along with the build-up of cooling degree-hours prior to the peak, is used to forecast Summer peaks.
3. The minimum and average temperatures on the peak day, along with the build-up of heating degree-hours based on 66^{o} F, one and two days prior to the peak, are used to forecast Winter peaks.

The cooling degree-hours and winter heating degree-days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. Heating degree-days based on 45^{o} F are used to capture heating load resulting from sustained periods of unusually cold weather not fully captured by heating degree-days based on 66^{o} F. A composite hourly temperature profile is derived using hourly temperatures across FPL's service territory. Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained. In developing the composite hourly profile, these regional temperatures are weighted by regional energy sales. The resulting composite temperature is used to derive projected cooling and heating degree-hours and heating degree-days. Similarly, composite temperature and hourly profiles of temperatures are used to calculate the weather variables used in the Summer and Winter peak models.

II. B. Comparison of FPL's Current and Previous Load Forecasts

While reflecting some fluctuations by year, FPL's current load forecast is generally in line with the load forecast presented in its 2013 Site Plan. There are four primary factors that are driving the current load forecast: projected population growth, the continued recovery of the Florida economy, energy efficiency codes and standards, and the additional load expected as a result of the acquisition of the City of Vero Beach electric utility.

In early 2013, FPL came to an agreement with the City of Vero Beach to purchase the City's electric system. This agreement was approved by the City voters on March 12, 2013. Beginning in January 2015, NEL, customers, and peaks for Vero Beach are included in FPL's forecasts and are reflected in FPL's 2014 Site Plan.

The customer forecast is based on recent population projections as well as the actual levels of customer growth experienced historically and the additional customers expected as a result of the acquisition of Vero Beach. Population projections are derived from the EDR's July 2013 Demographic Estimating Conference. This forecast is generally consistent with previous forecasts indicating a gradual rebound in Florida's population growth. Net migration into Florida fell to a record low in 2009 during the height of the recession. Florida has since experienced an improvement in net migration which now accounts for a majority of the population growth. However, population growth rates have remained modest by historical standards. Moderately higher rates of population growth are projected from 2014 until 2018 when the projected rate of population growth gradually begins to decelerate. Consistent with past population projections, the rates of population growth in the later years of the forecast are below the rates historically experienced in Florida.

Effective January 2015, FPL is expected to begin providing electric service to more than 34,000 customers formerly served by the City of Vero Beach. Reflecting this increase, the current forecast shows an increase in customer growth in 2015. Thereafter, customer growth is expected to mirror the overall level of population growth in the state. By 2019, the total number of customers served by FPL is expected to exceed five million. Between 2013 and 2023 the total number of customers is projected to increase at an annual rate of 1.4%, the same increase projected in the 2013 Site Plan.

The economic projections incorporated into FPL's load forecast are provided by IHS Global Insight, a leading economic forecasting firm. IHS Global Insight projects a continued recovery in the Florida economy with relatively healthy increases in employment and income levels between 2014 and 2020. Particularly robust growth is projected for the tourism and healthcare industries. Consistent with past projections, economic growth in the later years of the forecast is expected to moderate slightly.

Estimates of savings from energy efficiency codes and standards are developed by ITRON, a leading expert in this area. Included in these estimates are savings from federal and state energy efficiency codes and standards, including the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the savings occurring from the use of compact fluorescent bulbs[2]. The impact of these savings began in 2005 and their cumulative impact on the Summer peak is expected to reach 3,477 MW by 2023, the equivalent of approximately a 12% reduction in what the forecasted Summer peak load for 2023 would have been without these codes and standards. The cumulative impact from these savings on NEL is expected to reach 9,991 GWH over the same period while the cumulative impact on the Winter peak is expected to be 1,689 MW by 2023. This represents a decrease of approximately 7% in the forecasted NEL for 2023 and a 4% reduction in forecasted Winter peak load for 2023.

Consistent with the forecast presented in FPL's 2013 Site Plan, the total growth projected for the ten-year reporting period of this document is significant. The Summer peak is projected to increase to 26,528 MW by 2023, an increase of 4,952 MW over the 2013 actual Summer peak. Likewise, NEL is projected to reach 132,357 GWH in 2023, an increase of 20,702 GWH from the actual 2013 value.

II.C. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for the major revenue classes and are adjusted to match the NEL forecast. The results of these sales forecasts for the years 2014 - 2023 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical software package MetrixND. The methodologies used to develop energy sales forecasts for each jurisdictional revenue class and NEL forecast are outlined below.

[2] Note that in addition to the fact that these energy efficiency codes and standards lower the forecasted load (as described later in this chapter), these standards also lower the potential for efficiency gains that would otherwise be available through utility DSM programs.

1. Residential Sales

Residential electric usage per customer is estimated by using an econometric model. Residential sales are a function of the following variables: cooling degree-hours, winter heating degree-days, lagged cooling degree-hours, lagged winter heating degree-days, retail gasoline prices, and Florida real per capita income weighted by the percent of the population employed. The impact of weather is captured by the cooling degree-hours, heating degree-days, and the one month lag of these variables. The impact energy prices have on electricity consumption is captured through retail gasoline prices. As energy prices rise, less disposable income is available for all goods and services, electricity included. To capture economic conditions, the model includes a composite variable based on Florida real per capita income and the percent of the state's population that is employed. Residential energy sales are forecasted by multiplying the forecasted residential use per customer by the number of residential customers forecasted.

2. Commercial Sales

The commercial sales forecast is also developed using an econometric model. Commercial sales are a function of the following variables: Florida real per capita income weighted by the percent of the population employed, cooling degree-hours, heating degree-hours, lagged cooling degree-hours, a variable designed to reflect the impact of empty homes, dummy variables for the month of December and for the specific months of January 2007, November 2005, and March 2013, and an autoregressive term. Cooling degree-hours, heating degree-hours, and the one month lag of cooling degree-hours are used to capture weather-sensitive load in the commercial sector.

3. Industrial Sales

The industrial class is comprised of three distinct groups: very small accounts (those with less than 20 kW of demand), medium accounts (those with 21 kW to 499 kW of demand), and large accounts (those with demands of 500 kW or higher). As such, the forecast is developed using a separate econometric model for each group of industrial customers. The small industrial sales model utilizes the following variables: cooling degree-hours, heating degree-hours, dummy variables for the specific months of November 2005 and August 2004, and two autoregressive terms. The medium industrial sales model utilizes the following variables: cooling degree-hours, Florida real per capita income weighted by the percent of the population employed, dummy variables for the specific months of February 2005 and 2006 and November 2005, and three autoregressive terms,. The large industrial sales model utilizes the following variables: cooling degree-hours, Florida real per capita income weighted by the percent of the population employed, the Consumer Price Index, and dummy variables for the specific months of October 2004 and 2005, November 2004, and September 2005.

4. Railroad and Railways Sales and Street and Highway Sales

This class consists solely of Miami-Dade County's Metrorail system. The projections for railroad and railways sales are based on a historical moving average.

The forecast for street and highway sales is developed by first developing a trended use per customer value, then multiplying this value by the number of forecasted customers.

5. Other Public Authority Sales

This class consists of a sports field rate schedule, which is closed to new customers, and one government account. The forecast for this class is based on its historical usage characteristics.

6. Total Sales to Ultimate Customer

Sales forecasts by revenue class are summed to produce a total sales forecast.

7. Sales for Resale

Sales for resale (wholesale) customers are composed of municipalities and/or electric co-operatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers. Currently there are five customers in this class: the Florida Keys Electric Cooperative; Lee County Electric Cooperative; Wauchula; Winter Park; and Blountstown. In addition, FPL will begin making sales to Seminole Electric Cooperative in June 2014 under a long term agreement[3].

Beginning in May 2011, FPL began providing service to the Florida Keys Electric Cooperative under a long-term full requirements contract. Previously FPL was serving the Florida Keys under a partial requirements contract. The sales to Florida Keys Electric Cooperative are based on customer-supplied information and historical coincidence factors.

Lee County has contracted with FPL for FPL to supply a portion of their load through 2013, then to begin serving their entire load beginning in 2014. This contract began in January 2010. Lee County provides a forecast of their sales by delivery point which is used to derive their sales forecast.

FPL's sales to Wauchula began in October 2011 and will continue through December 2016.

[3] FPL continues to evaluate the possibility of serving the electrical loads of other entities at the time the 2014 Site Plan is being prepared. Because these possibilities are still being evaluated, the load forecast presented in this Site Plan does not include these potential loads.

Sales to Winter Park began in January 2014 and will continue through December 2016.

Blountstown became an FPL wholesale customer in May 2012. FPL's contract with Blountstown expires in April 2017.

A new contract with Seminole Electric Cooperative is included in the forecast which includes delivery of 200 MW beginning in June 2014 and continuing through May 2021.

II.D. Net Energy for Load (NEL)

An econometric model is developed to produce a NEL per customer forecast. The inputs to the model include Florida real per capita income weighted by the percent of the population employed, and a proxy for energy prices. The model also includes several weather variables including cooling degree-hours and heating degree-days by calendar month, and heating degree-days based on 45^{o} F. In addition, the model also includes variables for energy efficiency codes and standards and a variable designed to capture the impact of empty homes. Dummy variables are included for the specific months of May 2004, and November 2005. There is also an autoregressive term in the model.

The energy efficiency variable is included to capture the impacts from major codes and standards, including those associated with the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the savings occurring from the use of compact fluorescent bulbs. The estimated impact from these codes and standards is inclusive of engineering estimates and any resulting behavioral changes. The impact of these savings began in 2005 and their cumulative impact on NEL is expected to reach 9,991 GWH by 2023. This represents a 7.0% reduction in what the forecasted NEL for 2023 would have been absence these codes and standards. On an incremental basis, net of the reduction already experienced through 2013, the reduction in 2023 is expected to reach 6,075 GWH.

The decline in the number of empty homes resulting from the current housing recovery has affected use per customer and is captured in a separate variable. The forecast was also adjusted for additional load estimated from hybrid vehicles, beginning in 2013, which resulted in an increase of approximately 1,587 GWH by the end of the ten-year reporting period. The forecast was also adjusted for the incremental load resulting from FPL's economic development riders which began in 2013, and this incremental load is projected to grow to 537 GWH before leveling off in 2018. An additional adjustment to the NEL forecast was made to reflect the acquisition of the Vero Beach electric system. The Vero Beach acquisition is projected to add 793 GWH by 2023.

The NEL forecast is developed by first multiplying the NEL per customer forecast by the total number of customers forecasted (excluding the customers formerly served by Vero Beach) and then adjusting the forecasted results for the expected incremental load resulting from hybrid vehicles, new wholesale contracts, the Vero Beach acquisition, and FPL's economic development riders. Once the NEL forecast is obtained, total billed sales are computed using a historical ratio of sales to NEL. The sales by class forecasts previously discussed are then adjusted to match the total billed sales. The forecasted NEL values for 2014 - 2023 are presented in Schedule 3.3 that appears at the end of this chapter.

II.E. System Peak Forecasts

The rate of absolute growth in FPL system peak load has been a function of the size of the customer base, varying weather conditions, projected economic conditions, changing patterns of customer behavior, and more efficient appliances and lighting. FPL developed the peak forecast models to capture these behavioral relationships. In addition, FPL's peak forecast also reflects changes in load expected as a result of the acquisition of Vero Beach, changes in wholesale contracts, and the expected number of hybrid vehicles.

The savings from energy efficiency codes and standards incorporated into the peak forecast include the impacts from the 2005 National Energy Policy Act, the 2007 Energy Independence and Security Act, and the use of compact fluorescent light bulbs. The impact from these energy efficiency standards began in 2005 and their cumulative impact on the Summer peak is expected to reach 3,477 MW by 2023. This reduction is inclusive of engineering estimates and any resulting behavioral changes. The cumulative 2023 impact from these energy efficiency codes and standards effectively reduces FPL's Summer peak for that year by 11.6%. On an incremental basis, net of the reduction already experienced through 2013, the impact on the Summer peak from these energy efficiency codes and standards is expected to reach 1,997 MW in 2023. By 2023, the Winter peak is expected to be reduced by 1,689 MW as result of the cumulative impact from these energy efficiency standards since 2005. On an incremental basis, net of the reduction already experienced through 2013, the impact on the Winter peak from these energy efficiency standards is expected to reach 1,065 MW in 2023.

The forecast was also adjusted for additional load estimated from hybrid vehicles which results in an expected increase of approximately 443 MW in the Summer and 221 MW in the Winter by the end of the ten-year reporting period and for the acquisition of the Vero Beach electric system. The Vero Beach acquisition will add 169 MW to the Summer peak, and 179 MW to the Winter peak, forecast by the end of the ten-year reporting period.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2014 – 2023 are presented at the end of this chapter in Schedules 3.1 and 3.2, and in Chapter III in Schedules 7.1 and 7.2.

1. System Summer Peak

The Summer peak forecast is developed using an econometric model. The variables included in the model are the price of gasoline, lagged one month, Florida real household disposable income, cooling degree-hours two days prior to the peak day, the maximum temperature on the day of the peak, a variable for energy efficiency standards, and a moving average term. The model is based on the Summer peak contribution per customer which is multiplied by total customers (excluding the customers that have been served by Vero Beach), and adjusted to account for incremental loads resulting from hybrid vehicles, new wholesale contracts, the Vero Beach acquisition, and FPL's economic development riders to derive FPL's system Summer peak.

2. System Winter Peak

Like the system Summer peak model, this model is also an econometric model. The model consists of three weather-related variables: the average temperature on the peak day, heating degree-hours for the prior day squared, and heating degree-hours two days prior to the peak day. The model also includes two dummy variables; one for Winter peaks occurring on weekends and one for winter peaks with minimum temperature below 40.5 degrees. Also included in the model are a variable for housing starts per capita, and an autoregressive term. The forecasted results are adjusted for the impact of energy efficiency standards. The model is based on the Winter peak contribution per customer which is multiplied by total customers (excluding the customers that have been served by Vero Beach), and then adjusted for the expected incremental loads resulting from hybrid vehicles, new wholesale contracts, the Vero Beach acquisition, and FPL's economic development riders.

3. Monthly Peak Forecasts

The forecasting process for monthly peaks consists of the following steps:

a. The forecasted annual summer peak is assumed to occur in the month of August. The month of August has historically accounted for more annual summer peaks than any other month.

b. The forecasted annual winter peak is assumed to occur in the month of January. The month of January has historically accounted for more annual winter peaks than any other month.

c. The remaining monthly peaks are forecasted based on the historical relationship between the monthly peaks and the annual summer peak.

II.F. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2014 - 2023 are produced using a System Load Forecasting "shaper" program. This model uses years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. The model generates a projection of hourly load values based on these load shapes and the forecast of monthly peaks and energy.

II.G. Uncertainty

In order to address uncertainty in the forecasts of aggregate peak demand and NEL, FPL first evaluates the assumptions underlying the forecasts. FPL takes a series of steps in evaluating the input variables, including comparing projections from different sources, identifying outliers in the series, and assessing the series' consistency with past forecasts. As needed, FPL reviews additional factors which may affect the input variables.

Uncertainty is also addressed in the modeling process. Generally, econometric models are used to forecast the aggregate peak demand and NEL. During the modeling process, the relevant statistics (goodness of fit, F-statistic, P-values, mean absolute deviation (MAD), mean absolute percentage error (MAPE), etc.) are scrutinized to ensure that the models adequately explain historical variation. Once a forecast is developed, it is compared with past forecasts. Deviations from past forecasts are examined in light of changes in input assumptions to ensure that the drivers underlying the forecast are well understood. Finally, forecasts of aggregate peak demand and NEL are compared with the actual values as these become available. An ongoing process of variance analyses is performed. To the extent that the variance analysis identifies large unexplained deviations between the forecast and actual values, revisions to the econometric model may be considered.

The inherent uncertainty in load forecasting is addressed in different ways in regard to FPL's overall resource planning and operational planning work. In regard to FPL's resource planning work, FPL's utilization of a 20% total reserve margin criterion, and a 10% generation-only reserve margin criterion, are designed to maintain reliable electric service to FPL's customers in light of forecasting (and other) uncertainty. In addition, banded forecasts of the projected Summer peak and net energy for load are produced based on an analysis of past forecasting variances. In regard to operational planning, a banded forecast for the projected Summer and Winter peak days is developed based on the historical weather variations. These bands are then used to develop similar bands for the monthly peaks.

II.H. DSM

The effects of FPL's DSM energy efficiency programs implementation through August 2013 are assumed to be imbedded in the actual usage data for forecasting purposes. The impacts of incremental energy efficiency that FPL plans to implement in the future, plus the cumulative and projected incremental impacts of FPL's load management programs, are accounted for as "line item reductions" to the forecasts as part of the IRP process as shown in Chapter III in Schedules 7.1 and 7.2. After making these adjustments to the load forecasts, the resulting "firm" load forecast is then used in FPL's IRP work.

Schedule 2.1
History of Energy Consumption
And Number of Customers by Customer Class

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)

2013	2,956	9,541	309,772	88	442	28	102,784

Historical Values (2004 - 2013):

Col. (10) and Col.(15) represent actual energy sales including the impacts of existing conservation. These values are at the meter.

Col. (11) represents the annual average of the twelve monthly values.

Col. (16) = Col. (4) + Col. (7) + Col. (10) + Col. (13) + Col. (14) + Col. (15).

2023	2,692	11,907	226,087	83	499	23	120,210

Projected Values (2014 - 2023):

Col. (10) and Col.(15) represent forecasted energy sales that do not include the impact of incremental conservation. These values are at the meter.

Col. (11) represents the annual average of the twelve monthly values.

Col. (16) = Col. (4) + Col. (7) + Col. (10) + Col. (13) + Col. (14) + Col. (15).

Schedule 2.3
History of Energy Consumption
And Number of Customers by Customer Class

(1) Year	(17) Sales for Resale GWh	(18) Utility Use & Losses GWh	(19) Net Energy For Load GWh	(20) Average No. of Other Customers	(21) Total Average Number of Customers
2004	1,531	7,467	108,093	3,029	4,224,509
2005	1,506	7,498	111,301	3,156	4,321,895
2006	1,569	7,909	113,137	3,218	4,409,563
2007	1,499	7,401	114,315	3,276	4,496,589
2008	993	7,092	111,004	3,348	4,509,730
2009	1,155	7,394	111,303	3,439	4,499,067
2010	2,049	7,870	114,475	3,523	4,520,328
2011	2,176	6,950	112,454	3,596	4,547,051
2012	2,237	6,403	110,866	3,645	4,576,449
2013	2,158	6,713	111,655	3,722	4,626,934

Historical Values (2004 - 2013):

Col. (19) represents actual energy sales including the impacts of existing conservation.

Col. (19) = Col. (16) + Col. (17) + Col. (18). Historical NEL includes the impacts of existing conservation and agrees to Col. (5) on schedule 3.3. Historical GWH, prior to 2011, are based on a fiscal year beginning 12/29 and ending 12/28. The 2011 value is based on 12/29/10 to 12/31/11. The 2012-2013 values are based on calendar year.

Col. (20) represents the annual average of the twelve monthly values.

Col. (21) = Col. (5) + Col. (8) + Col. (11) + Col. (20).

Schedule 2.3
Forecast of Energy Consumption
And Number of Customers by Customer Class

(1) Year	(17) Sales for Resale GWh	(18) Utility Use & Losses GWh	(19) Net Energy For Load GWh	(20) Average No. of Other Customers	(21) Total Average Number of Customers
2014	4,907	6,662	118,001	3,780	4,680,054
2015	5,654	6,703	121,606	4,323	4,782,469
2016	5,706	6,775	123,943	4,383	4,852,827
2017	5,419	6,811	124,914	4,437	4,922,918
2018	5,440	6,896	126,399	4,491	4,991,659
2019	5,496	6,959	127,673	4,543	5,058,945
2020	5,559	7,035	129,187	4,592	5,123,909
2021	5,133	7,018	129,454	4,638	5,185,333
2022	4,846	7,124	130,517	4,681	5,247,054
2023	4,908	7,239	132,357	4,724	5,309,376

Projected Values (2014 - 2023):

Col. (19) represents forecasted energy sales that do not include the impact of incremental conservation and agrees to Col. (2) on Schedule 3.3.

Col. (19) = Col. (16) + Col. (17) + Col. (18). These values are based on calendar year.

Col. (20) represents the annual average of the twelve monthly values.

Col. (21) = Col. (5) + Col. (8) + Col. (11) + Col. (20).

Schedule 3.1
History of Summer Peak Demand (MW)

(1) Year	(2) Total	(3) Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management	(7) Residential Conservation	(8) C/I Load Management	(9) C/I Conservation	(10) Net Firm Demand
2004	20,545	258	20,287	0	894	846	588	577	19,063
2005	22,361	264	22,097	0	902	895	600	611	20,858
2006	21,819	256	21,563	0	928	948	635	640	20,256
2007	21,962	261	21,701	0	952	982	716	683	20,295
2008	21,060	181	20,879	0	966	1,042	760	706	19,334
2009	22,351	249	22,102	0	981	1,097	811	732	20,558
2010	22,256	419	21,837	0	990	1,181	815	758	20,451
2011	21,619	427	21,192	0	1,000	1,281	821	781	19,798
2012	21,440	431	21,009	0	1,013	1,351	833	810	19,594
2013	21,576	396	21,180	0	1,025	1,394	833	827	19,718

Historical Values (2004 - 2013):

Col. (2) - Col. (4) are actual values for historical Summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) represent actual DSM capabilities starting from January 1988 and are annual (12-month) values except for 2013 values which are through August.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" as if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col.(2) - Col.(6) - Col.(8).

Schedule 3.1
Forecast of Summer Peak Demand (MW)

(1) August of Year	(2) Total	(3) Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management*	(7) Residential Conservation	(8) C/I Load Management*	(9) C/I Conservation	(10) Net Firm Demand
2014	22,768	1,173	21,595	0	1,077	65	816	33	20,777
2015	23,356	1,206	22,149	0	1,093	88	830	46	21,298
2016	23,778	1,212	22,565	0	1,103	89	841	49	21,695
2017	24,190	1,159	23,031	0	1,113	91	853	52	22,081
2018	24,544	1,166	23,378	0	1,124	92	865	56	22,407
2019	24,896	1,172	23,723	0	1,134	94	877	62	22,729
2020	25,239	1,179	24,061	0	1,144	97	889	67	23,042
2021	25,439	985	24,454	0	1,154	100	901	73	23,211
2022	25,908	992	24,916	0	1,165	104	912	79	23,648
2023	26,528	998	25,530	0	1,175	109	924	85	24,235

Projected Values (2014 - 2023):

Col. (2) - Col. (4) represent FPL's forecasted peak and does not include incremental conservation, cumulative load management, or incremental load management.

Col. (5) - Col. (9) represent cumulative load management, and incremental conservation and load management. All values are projected August values.

Col. (8) represents FPL's Business On Call, CDR, CILC, and Curtailable programs/rates.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

* Res. Load Management and C/I Load Management include MW values of load management from Lee County and FKEC.

Schedule 3.2
History of Winter Peak Demand:Base Case

(1) Year	(2) Total	(3) Firm Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management	(7) Residential Conservation	(8) C/I Load Management	(9) C/I Conservation	(10) Net Firm Demand
2004	14,752	211	14,541	0	813	567	534	227	13,405
2005	18,108	225	17,883	0	816	583	542	233	16,751
2006	19,683	225	19,458	0	823	600	550	240	18,311
2007	16,815	223	16,592	0	846	620	577	249	15,392
2008	18,055	163	17,892	0	868	644	636	279	16,551
2009	20,081	207	19,874	0	881	666	676	285	18,524
2010	24,346	500	23,846	0	895	687	721	291	22,730
2011	21,126	383	20,743	0	903	717	723	303	19,501
2012	17,934	382	17,552	0	856	755	722	314	16,356
2013	15,931	348	15,583	0	843	781	567	326	14,521

Historical Values (2004 - 2013):

Col. (2) - Col. (4) are actual values for historical Winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand. For year 2011, the actual peaked occurred in December of 2010.

Col. (5) - Col. (9) for 2003 through 2012 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" as if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col.(2) - Col.(6) - Col.(8).

Schedule 3.2
Forecast of Winter Peak Demand:Base Case

(1) January of Year	(2) Total	(3) Firm Wholesale	(4) Retail	(5) Interruptible	(6) Res. Load Management*	(7) Residential Conservation	(8) C/I Load Management*	(9) C/I Conservation	(10) Net Firm Demand

2023	22,891	974	21,918	0	970	56	601	24	21,240

Projected Values (2014 - 2023):

Col. (2) - Col. (4) represent FPL's forecasted peak and does not include incremental conservation, cumulative load management, or incremental load management.

Col. (5) - Col. (9) represent cumulative load management, and incremental conservation and load management. All values are projected January values.

Col. (8) represents FPL's Business On Call, CDR, CILC, and Curtailable programs/rates.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

* Res. Load Management and C/I Load Management include MW values of load management from Lee County and FKEC.

Schedule 3.3
History of Annual Net Energy for Load (GWh)
(All values are "at the generator" values except for Col (8))

(1) Year	(2) Net Energy For Load without DSM GWh	(3) Residential Conservation GWh	(4) C/I Conservation GWh	(5) **Actual** Net Energy For Load GWh	(6) Sales for Resale GWh	(7) Utility Use & Losses GWh	(8) Total Billed Retail Energy Sales (GWh)	(9) Load Factor(%)

2005	115,065	1,970	1,793	111,301	1,506	7,498	102,296	56.8%
2006	117,116	2,078	1,901	113,137	1,569	7,909	103,659	59.2%
2007	118,518	2,138	2,066	114,315	1,499	7,401	105,415	59.4%
2008	115,379	2,249	2,126	111,004	993	7,092	102,919	60.0%
2009	115,844	2,345	2,196	111,303	1,155	7,394	102,755	56.8%
2010	119,220	2,487	2,259	114,475	2,049	7,870	104,557	58.7%
2011	117,460	2,683	2,324	112,454	2,176	6,950	103,327	59.4%
2012	116,083	2,823	2,394	110,866	2,237	6,403	102,226	58.9%
2013	117,087	2,962	2,469	111,655	2,158	6,713	102,784	59.1%

Historical Values (2004 - 2013):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: Col. (2) = Col. (3) + Col. (4) + Col. (5).

Col. (3) & Col. (4) are DSM values starting in January 1988 and are annual (12-month) values. Col. (3) and Col. (4) for 2013 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWh reductions experienced each year .

Col. (5) is the actual Net Energy for Load (NEL) for years 2003 - 2013.

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (5) - Col. (6) - Col. (7). These values are at the meter.

Col. (9) is calculated using Col. (5) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (5)*1000) / ((Col. (2) * 8760)
Adjustments are made for leap years.

Schedule 3.3
Forecast of Annual Net Energy for Load (GWh)
(All values are "at the generator"values except for Col (8))

(1) Year	(2) Forecasted Net Energy For Load without DSM GWh	(3) Residential Conservation GWh	(4) C/I Conservation GWh	(5) Net Energy For Load Adjusted for DSM GWh	(6) Sales for Resale GWh	(7) Utility Use & Losses GWh	(8) Forecasted Total Billed Retail Energy Sales w/o DSM GWh	(9) Load Factor(%)
2014	118,001	91	53	117,858	4,907	6,662	106,432	59.2%
2015	121,606	142	80	121,383	5,654	6,703	109,248	59.4%
2016	123,943	144	81	123,718	5,706	6,775	111,463	59.3%
2017	124,914	147	81	124,686	5,419	6,811	112,684	58.9%
2018	126,399	150	81	126,168	5,440	6,896	114,063	58.8%
2019	127,673	155	80	127,438	5,496	6,959	115,218	58.5%
2020	129,187	159	81	128,948	5,559	7,035	116,593	58.3%
2021	129,454	164	82	129,208	5,133	7,018	117,303	58.1%
2022	130,517	170	82	130,264	4,846	7,124	118,548	57.5%
2023	132,357	179	83	132,095	4,908	7,239	120,210	57.0%

Projected Values (2014 - 2023):

Col. (2) represents Forecasted Net Energy for Load and does not include incremental DSM from 2013 - on. The Col. (2) values are extracted from Schedule 2.3, Col(19). The effects of conservation implemented prior to September 2012 are incorporated into the load forecast values in Col. (2).

Col. (3) & Col. (4) are forecasted values of the reduction on sales from incremental conservation from Jan 2014 - on and are mid-year (6-month) values reflecting DSM signups occurring evenly thoughout each year.

Col. (5) is the forecasted Net Energy for Load (NEL) after adjusting for impacts of incremental DSM for years 2014 - 2023 using the formula:
Col. (5) = Col. (2) - Col. (3) - Col. (4)

Col. (8) is the Total Retail Billed Sales. The values are calculated using the formula: Col. (8) = Col. (2) - Col. (6) - Col. (7).
These values are at the meter.

Col. (9) is calculated using Col. (2) from this page and Col. (2), "Total", from Schedule 3.1. Col. (9) = ((Col. (2)*1000) / ((Col. (2) * 8760)
Adjustments are made for leap years.

Schedule 4
Previous Year Actual and Two-Year Forecast of
Retail Peak Demand and Net Energy for Load (NEL) by Month

(1)	(2)	(3)	(4)	(5)	(6)	(7)

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL utilizes its well established integrated resource planning (IRP) process in whole or in part as analysis needs are warranted, to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of new power plants, the primary subjects of this document, are determined as part of the IRP process work.

This section describes FPL's basic IRP process. Some of the key assumptions, in addition to a new load forecast, that were used in developing the resource plan presented in this Site Plan are also discussed.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental steps to FPL's resource planning. These steps can be generally described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Evaluate the competing options and resource plans in regard to system economics and non-economic factors; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

Overview of FPL's IRP Process

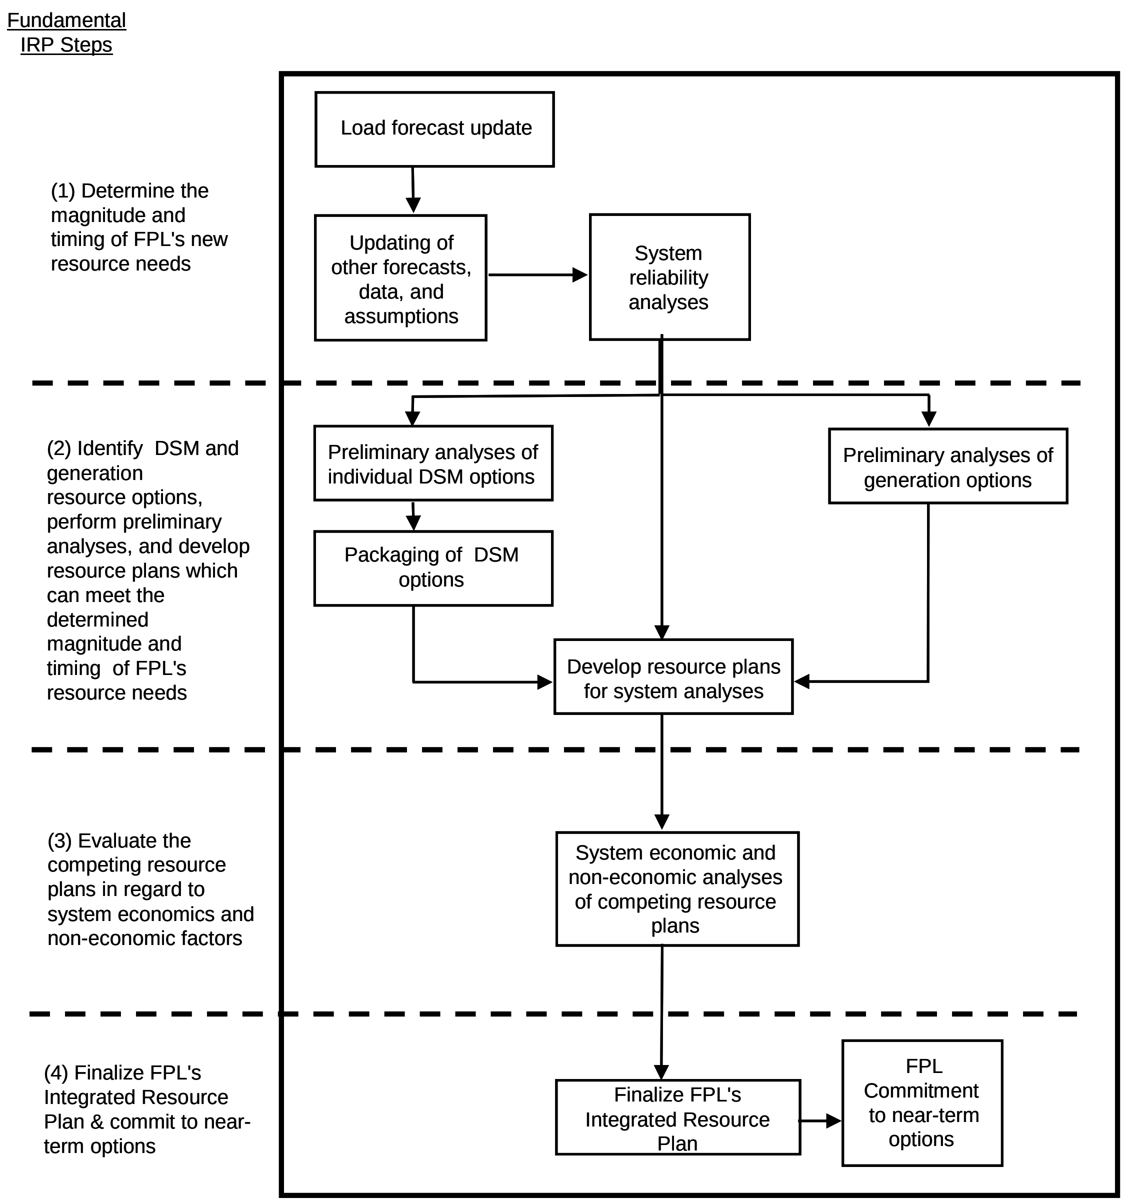

Figure III.A.1: Overview of FPL's IRP Process

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of the four resource planning steps, determining the magnitude and timing of FPL's resource needs, is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed to maintain system reliability. Also determined in this step is when the MW additions are needed to meet FPL's reliability criteria. This step is often referred to as a reliability assessment, or resource adequacy, analysis for the utility system.

Step 1 typically starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information that is used in many of the fundamental steps in resource planning. Examples of this new information include, but are not limited to: delivered fuel price projections, current financial and economic assumptions, and power plant capability and operating assumptions. FPL also includes key sets of assumptions regarding three specific types of resources: (1) FPL unit capacity changes, (2) firm capacity power purchases, and (3) demand side management (DSM) implementation.

Key Assumptions Regarding the Three Types of Resources:

The first set of assumptions, FPL unit capacity changes, is based on the current projection of new generating capacity additions and planned retirements of existing generating units. In FPL's 2014 Site Plan, there are five such projected capacity changes. These are listed below in chronological order:

1) Planned retirement of existing Putnam Units 1 & 2:

   Analyses conducted during 2013 and early 2014 showed that it would be cost-effective to retire the two existing units, Putnam Units 1 & 2, and replace the capacity with new combined cycle (CC) capacity at a later date and at a site to be determined. The new CC capacity would have a significantly better heat rate, thus reducing FPL's system fuel usage and system emissions. Consequently, FPL currently projects that the two existing units will be retired by the end of 2014.

2) CT upgrades at existing CC plant sites:

   In the fourth quarter of 2011, FPL started upgrading the 7FA combustion turbines (CT) that are components at a number of its existing CC units. These upgrades will economically benefit FPL's customers by increasing the MW output of these CC units by approximately 209 MW (Summer peak value) in total. As reflected in Schedule 1 in Chapter I, 133 MW of the increased capacity from these CT upgrades is already in service. The work for the remaining upgrades is continuing and the project is projected to be completed in 2015.

3) Modernization of the Port Everglades plant site:

The work to modernize the existing Port Everglades site by adding new combined cycle (CC) capacity continues. The new generating unit, called the Port Everglades Next Generation Clean Energy Center (PEEC), is projected to be in-service in mid-2016 and is projected to have a peak Summer output of 1,237 MW. The FPSC issued the final need order for this modernization project in April 2012 in Order No. PSC-12-0187-FOF-EI. The site certification order for the project, DOAH Case No. 12-0422EPP, was received for the Port Everglades project in October 2012. (Note that a similar modernization of the FPL's existing Riviera Beach plant site is scheduled to be completed on/near the April 1, 2014 filing date of this 2014 Site Plan.)

4) Retirement of existing gas turbines (GTs) in Broward County and partial capacity replacement with new combustion turbines (CTs) at FPL's Lauderdale plant site:

Due to new nitrogen dioxide (NO_2) environmental regulations, FPL filed in June 2013 for FPSC approval to recover costs for removing all of its existing GTs and replacing a portion of the GT capacity with new CTs. In December 2013, FPL withdrew this request pending additional environmental monitoring and analyses. Computer modeling of the emissions from the GTs projected that the GTs would exceed the new NO_2 limit. FPL believes this monitoring and analyses will confirm that the operation of its existing GTs in Broward County will not comply with the new NO_2 regulations. Therefore, for planning purposes, FPL has assumed that all of its existing Broward County GTs will be removed (a loss of 1,260 MW Summer) and that this capacity will be partially replaced by 5 new CTs that would be sited in Broward County (an increase of 1,005 MW Summer). This GT removal and CT partial replacement is assumed to occur by the end of 2018.

5) Turkey Point Nuclear Units 6 & 7:

FPL is continuing its work to obtain all of the licenses, permits, and approvals that will be necessary to construct and operate two new nuclear units at its Turkey Point site. These licenses, permits, and approvals will provide FPL with the opportunity to construct these nuclear units at Turkey Point for a time expected to be up to 20 years from the time the licenses and permits are granted, and then to operate the units for at least 40 years thereafter. FPL received need determination approval from the FPSC for the two nuclear units in April 2008 in Order No. PSC-08-0237-FOF-EI. The earliest deployment dates for these two new units, Turkey Point Units 6 & 7, remain 2022 and 2023, respectively. Each new nuclear unit is projected to have a peak Summer output of 1,100 MW.

Also in regard to FPL unit capacity changes, as part of FPL's planned acquisition of Vero Beach's electric utility system, FPL is projected to take ownership of Vero Beach's five existing generating units starting January 2015. The current plan, based on the units' poor economics, is to immediately retire three of these older generating units and operate the remaining two, which supply approximately 46 MW (Summer) of combined cycle capacity, for a maximum of three years.

The second set of assumptions involves firm capacity power purchases. FPL's current projection of firm capacity purchases has changed from the projection in the 2013 Site Plan in regard to only two purchases. As part of the projected agreement that FPL will begin serving Vero Beach's electrical needs beginning in January 2015, FPL has acquired two existing power purchase agreements totaling approximately 37 MW of coal-fired capacity. These agreements are now projected to run through the end of 2017 instead of 2016 as projected in FPL's 2013 Site Plan. In addition, FPL now projects that Internal Revenue Service (IRS) regulations regarding the amount of energy that FPL can receive under its purchase agreement with Jacksonville Electric Authority (JEA) for St. Johns Regional Power Park (SJRPP)-based capacity and energy will not result in the suspension of the delivery of capacity and energy receipts to FPL until April 2019. [4]

None of the other purchase projections has changed from those in the 2013 Site Plan. FPL's current projection includes an additional 70 MW from the Palm Beach Solid Waste Authority (SWA) starting in year 2015. In addition, FPL projects that it will begin receiving a total of 180 MW of firm capacity in 2021 from biomass-based power purchase agreements with EcoGen.

In total, the projected firm capacity purchases are from a combination of utility and independent power producers. Details, including the annual total capacity values for these purchases, are presented in Chapter I in Tables I.B.1 and I.B.2. These purchased capacity amounts were incorporated in FPL's resource planning work.

The third set of assumptions involves a projection of the amount of additional DSM that is anticipated to be implemented annually over the ten-year period. A key aspect of FPL's IRP process is the evaluation of DSM resources. Since 1994, FPL's resource planning work has assumed that, at a minimum, the DSM MW called for in FPL's FPSC-approved DSM Plan will be achieved. In 2014, FPL is required to propose new DSM Goals for the 2015 through 2024 time period. Those proposed goals will be filed with the FPSC on April 2, 2014; i.e., one day after this 2014 Site Plan is filed with the FPSC. FPL's filing to support its proposed DSM goals provides extensive detail regarding how DSM resources were evaluated in FPL's most current IRP planning

[4] FPL's projected suspension date for the SJRPP purchase is based on a system reliability perspective and represents the earliest projected date at which the suspension of capacity and energy could occur.

analyses. The DSM assumptions presented in this 2014 Site Plan, and which are assumed in the analyses whose results are reflected in the Site Plan, are consistent with FPL's proposed goals. The FPSC is expected to make a decision regarding FPL's 2015 – 2024 DSM Goals later in 2014.

The Three Reliability Criteria Used to Determine FPL's Projected Resource Needs:

These key assumptions, plus the other updated information described above, are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's future resource needs. This determination is accomplished by system reliability analyses which for FPL have traditionally been based on dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry. Beginning this year, FPL is also using a third reliability criterion: a 10% generation-only reserve margin (GRM) criterion.

Historically, two types of methodologies, deterministic and probabilistic, have been utilized in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the reliability of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Among the most widely used is loss-of-load probability (LOLP) which FPL utilizes. Simply stated, LOLP is an index of how well a generating system may be able to meet its firm demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in terms of the projected probability that a utility will be unable to meet its entire firm load at some point during a year. The probability of not being able to meet the entire firm load is calculated for each day of the year using the daily peak hourly load. These daily probabilities are then summed to develop an annual probability value. This annual probability value is commonly expressed as "the number of days per year" that the entire system firm load could not be met. FPL's standard for LOLP, commonly accepted throughout the industry, is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program used by FPL.

FPL's recent integrated resource planning work has resulted in FPL's resource plans showing a significant shift in the mix of generation and DSM resources over the next 10 years in regard to the relative contribution of these resources to system reliability. In order to gauge the extent of this shift and its potential implications for FPL's system reliability, FPL developed a new metric: a generation-only reserve margin (GRM). This GRM metric reflects reserves that would be provided only by actual generating resources. The GRM value is calculated by setting to zero all incremental energy efficiency (EE) and load management (LM), plus all existing LM, in a reserve margin calculation. The resulting GRM value provides an indication of how large a role generation is projected to play in each year as FPL maintains its 20% Summer and Winter "total" reserve margins (which account for both generation and DSM resources).

FPL has been reporting the GRM metric in its Site Plans since 2011 when it presented projections of its Summer GRM for the years 2011-2020. The 2011 projection showed a steady decrease in GRM values from a "balanced" 11.5% in 2011 to much reduced 7.2% by 2020. In its 2012 Site Plan, FPL's projected GRM values steadily decreased over the 10-year period from 16.2% in 2012 to 5.5% in 2021. The projected pattern in the 2013 Site Plan was similar: a steady decrease from 16.3% in 2013 to 6.9% in 2021. (The projected GRM value for 2022 presented in the 2013 Site Plan increased to 8.9% due to the planned addition of the new Turkey Point 6 nuclear unit in 2022.) Thus FPL's resource planning projections over the last 3 years have each shown a general downwards trend in projected GRM in the latter portion of this decade. This indicates increasing reliance on DSM resources, particularly EE resource additions, and decreasing reliance on generation resources, to maintain system reliability. As a result, FPL has analyzed what impact(s) this trend could have on system reliability. Two types of evaluations were conducted. One of these evaluations is from the perspective of FPL's system operators who are responsible for operating the bulk electric system. The other evaluation is from a resource planning perspective.

The first evaluation examined what impact an increasing reliance on EE resource additions was projected to have on the amount and type of reserves that operators would have at their disposal to meet load on a system peak hour. FPL first used a "looking back" perspective at a recent actual peak load day of January 11, 2010 to see how the system actually operated. Then, assuming a "what if" situation in which the system was assumed to have been designed to have an identical total reserve margin, but higher and lower GRM respectively, FPL analyzed what the impact would have been on FPL's ability to serve its customers on that peak day with these alternative assumed systems.

FPL also performed analyses taking a "looking forward" perspective at the projected year of 2021. Three scenarios were analyzed: (i) the system with its projected GRM and total reserve margin values consistent with the 2013 Site Plan; (ii) a system with an identical total reserve margin, but a higher GRM; and (iii) a system with an identical total reserve margin, but a lower GRM. Recognizing that the impacts from EE resource additions will already have been accounted for in the peak load that system operators must react to on an actual peak day, the analyses assumed an adverse peak day situation which consisted of significantly higher load and significantly less available generation than projected. The results from both the "looking back" and "looking forward" analyses were similar. For resource plans with identical total reserve margins, but different GRM levels, system operators were projected to have significantly higher levels (MW) of reserves, either generation and/or load management reserves, available on the peak days with a resource plan that had a higher GRM level than with a resource plan that had a lower GRM level. Thus a resource plan with a higher GRM, compared with a lower GRM, results in better system reliability for customers due to a greater likelihood of meeting customers' firm demand on peak load days, despite unexpected conditions or events. Better system reliability to customers translates to a reduced risk of shedding firm load.

The second evaluation was from the resource planning perspective of loss-of-load-probability (LOLP). For this evaluation, FPL also analyzed resource plans with identical total reserve margins, but higher and lower GRM levels. The results of these analyses for the FPL system showed that a resource plan with a higher GRM resulted in a projection of lower LOLP values than a resource plan with a lower GRM.

Based on these operational and resource planning evaluations, FPL has concluded that resource plans for its system with identical total reserve margins, but different GRM values, are not equal in regard to system reliability. A resource plan with a higher GRM value is projected to result in more MW being available to system operators on adverse peak load days, and in lower LOLP values, than a resource plan with a lower GRM value, even though both resource plans have an identical total reserve margin. Therefore, FPL has applied a minimum GRM criterion as a third reliability criterion in its resource planning process.

Based on the expertise and experience of FPL's system operators regarding the amount of generation MW needed for reliable operations, the GRM criterion is set at a minimum of 10% for Summer and Winter. From an operational perspective, FPL believes it is necessary to have approximately 2,650 MW of generation reserves. These reserves will allow FPL to address a variety of operational considerations including: (i) unplanned generation unavailability; (ii) the deployment of real-time operating reserves to meet its 15-minute obligations as part of the Florida Reserve Sharing Group; (iii) the requirement pursuant to NERC Reliability Standards to replace with other resources within 30 minutes following the unplanned loss of a large generation unit; and (iv) higher-than-forecasted loads. The sum of the operational reserves to cover for these requirements and considerations is approximately 2,650 MW. This MW value is consistent with a 10% GRM for the foreseeable future. FPL is planning its system so that the minimum 10% GRM criterion is met beginning in the Summer of 2019.

The 10% minimum Summer and Winter GRM criterion augments the two existing reliability criteria used by FPL: a 20% total reserve margin criterion for Summer and Winter, and a 0.1 day/year LOLP criterion. The total reserve margin and LOLP criteria continue to identify the timing and magnitude of FPL's future resource needs. The GRM criterion provides direction regarding the mix of generation and DSM resources that should be added to maintain and enhance FPL's system reliability.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, preliminary economic screening analyses of new capacity options that are identical, or virtually identical, in regard to certain key characteristics may be conducted to determine which new capacity options appear to be the most competitive on FPL's system. This preliminary analysis work can also help identify capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs. Similarly, preliminary economic screening analyses of new DSM options and/or evaluation of existing DSM options are often conducted in this second fundamental IRP step.

FPL typically utilizes the P-MArea production cost model and a Fixed Cost Spreadsheet, and/or an optimization models and spreadsheet analyses, to perform the preliminary economic screening of generation resource options. For the preliminary economic screening analyses of DSM resource options, FPL typically uses its DSM CPF model which is an FPL spreadsheet model utilizing the FPSC's approved methodology for performing preliminary economic screening of individual DSM measures and programs. In addition, a years-to-payback screening test based on a two-year criterion is also used in the preliminary economic screening of individual DSM measures and programs. Then, as the focus of DSM analyses progresses from analysis of individual DSM measures to the development of DSM portfolios, FPL uses two additional models. One of these models is FPL's non-linear programming model that is used for analyzing the potential for lowering system peak loads through additional load management/demand response capability. The other model that FPL typically utilizes is its linear programming model with which FPL develops DSM portfolios.

The individual new resource options, both Supply options and DSM portfolios, emerging from these preliminary economic screening analyses are then typically "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's projected new resource needs are met. The creation of these competing resource plans is typically carried out using spreadsheet and/or dynamic programming techniques.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs are identified.

Step 3: Evaluate the Competing Options and Resource Plans in Regard to System Economics and Non-Economic Factors:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for evaluating these resource options and resource plans in system economic analyses that aim to account for all of the impacts to the FPL system from the competing resource options/resource plans. In FPL's 2013 and early 2014 resource planning work, once the resource plans were developed, FPL utilized the P-MArea production cost model and a Fixed Cost Spreadsheet, and/or the Strategist model, to perform the system economic analyses. Other spreadsheet models may also be used to further analyze the resource plans.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the objective generally being to minimize FPL's projected levelized system average electric rate (i.e., a Rate Impact Measure or RIM methodology). In analyses in which the DSM contribution has already been determined through the same IRP process and FPSC approval, and therefore the only competing options were new generating units and/or purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements will yield identical outcomes in regard to the relative rankings of the resource options being evaluated. Consequently, the competing options and resource plans in such cases can be evaluated on a system cumulative present value revenue requirement (CPVRR) basis.

Other factors are also included in FPL's evaluation of resource options and resource plans. While these factors may have an economic component or impact, they are often discussed in quantitative, but non-economic, terms such as percentages, tons, etc. rather than in terms of dollars. These factors are often referred to by FPL as "system concerns" that include (but are not limited to) maintaining/enhancing fuel diversity in the FPL system, system emission levels, and maintaining a regional balance between load and generating capacity, particularly in the Southeastern Florida counties of Miami-Dade and Broward. In conducting the evaluations needed to determine which resource options and resource plans are best for FPL's system, the non-economic evaluations are conducted with an eye to whether the system concern is positively or negatively impacted by a given resource option or resource plan. These, and other, factors are discussed later in this chapter in section III.C.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps are typically used to develop FPL's current resource plan. The current resource plan is presented in the following section.

III.B Projected Incremental Resource Additions/Changes in the Resource Plan

FPL's projected incremental generation capacity additions/changes for 2014 through 2023 are depicted in Table III.B.1. These capacity additions/changes include the 5 generation additions/changes previously discussed. The table shows three more generation changes: a CC unit being added in 2019, a short-term PPA of 129 MW being added in 2020, and a short-term PPA of 168 MW being added in 2021. The CC unit is added in 2019 to meet the Summer total reserve margin criterion and the two PPAs are added in 2020 and 2021 to meet the GRM criterion.

Although FPL's projected DSM additions that are developed in the IRP process are not explicitly presented in this table, these DSM additions have been fully accounted for in all of FPL's resource planning work reflected in this document. The projected MW reductions from these DSM additions are also reflected in the projected total reserve margin values shown in the table below and in Schedules 7.1 and 7.2 presented later in this chapter. DSM is further addressed later in this chapter in section III.D.

III.C Discussion of the Projected Resource Plan and Issues Impacting FPL's Resource Planning Work

As indicated in the Executive Summary, FPL's resource planning efforts in 2013 and early 2014 were influenced by a number of factors. These factors are expected to continue to influence FPL's resource planning work for the foreseeable future. In addition, other factors may also influence FPL's on-going resource planning work in the future and may result in changes to the resource plan discussed in this document. Eight (8) of these factors are discussed below (in no particular order of importance).

1) Maintaining/enhancing fuel diversity in the FPL system;
2) Maintaining a balance between load and generating capacity in Southeastern Florida, particularly in Miami-Dade and Broward Counties;
3) Updated projections of Federal and state energy efficiency codes and standards;
4) Decline in the projected cost-effectiveness of utility DSM measures and programs;
5) FPL's growing dependence upon DSM resources to maintain system reliability;
6) The schedule for the new Turkey Point Nuclear Units 6 & 7;
7) Environmental regulation and/or legislation; and,
8) Possible establishment of a Florida standard for renewable energy or clean energy.

These 8 factors, and their various impacts on FPL's resource planning efforts including the current resource plan that is presented in this Site Plan, are briefly discussed below.

1. Maintaining/Enhancing System Fuel Diversity:

FPL currently uses natural gas to generate approximately 2/3 of the total electricity it delivers to its customers. In the future, the percentage of FPL's electricity that is generated by natural gas is projected to remain at a high level. For this reason, and due to evolving environmental regulations, FPL is continually seeking opportunities to economically maintain and enhance the fuel diversity of its system.

In 2007, following express direction by the FPSC to do so, FPL sought approval from the FPSC to add two new advanced technology coal units to its system. These two new units would have been placed in-service in 2013 and 2014. However, in part due to concerns over potential greenhouse gas emission legislation/regulation, FPL was unable to obtain approval for these units. Several other factors are currently unfavorable to new coal units compared to new CC units. The first of these factors is a significant reduction in the fuel cost difference between coal and natural gas compared to the fuel cost difference projected in 2007 that favored coal; i.e., the projected fuel cost advantage of coal versus natural gas has been significantly reduced. Second is the continuation of significantly higher capital costs for coal units compared to capital costs for CC units. Third is the increased fuel efficiency of new CC units compared to projected CC unit efficiencies in 2007. Fourth are existing and proposed environmental regulations, including those that address greenhouse gas emissions, that are unfavorable to new coal units when compared to new CC units. Consequently, FPL does not believe that new advanced technology coal units are currently economically, politically, or environmentally viable fuel diversity enhancement options in Florida.

Therefore, FPL has turned its attention to nuclear energy and renewable energy to enhance its fuel diversity, to diversifying the sources of natural gas, to diversifying the gas transportation paths used to deliver natural gas to FPL's generating units, and to using natural gas more efficiently. In regard to nuclear energy, in 2008 the FPSC approved the need to increase capacity at FPL's four existing nuclear units and authorized FPL to recover project-related expenditures that are approved as a result of annual nuclear cost recovery filings. FPL has now successfully completed the nuclear capacity uprate project. Approximately 520 MW of additional nuclear capacity were delivered by the project which represents an increase of approximately 30% more capacity than was originally forecasted when the project began. FPL's customers are already benefitting from lower fuel costs and reduced system emissions provided by this additional nuclear capacity.

FPL is continuing its work to obtain all of the licenses, permits, and approvals that would be necessary to construct and operate two new nuclear units at its Turkey Point site in the future. These licenses, permits, and approvals will provide FPL with the opportunity to construct these nuclear units at Turkey Point for a time expected to be up to 20 years from the time the licenses and permits are granted, and then to operate the units for at least 40 years thereafter. The earliest deployment dates for the two new nuclear units, Turkey Point Units 6 & 7, remain 2022 and 2023, respectively.

FPL also has been involved in activities to investigate adding or maintaining renewable resources as a part of its generation supply. One of these activities is a variety of discussions with the owners of existing facilities aimed at maintaining or extending current agreements. In addition, FPL considers new cost-effective renewable energy projects such as the power purchase agreements with EcoGen that will result in FPL receiving 180 MW of firm capacity from biomass facilities beginning in 2021.

FPL also sought and received approval from the FPSC in 2008 to add 110 MW through three new FPL-owned solar facilities: one solar thermal facility and two photovoltaic (PV) facilities.

One 25 MW PV facility began commercial operation in 2009. The remaining two solar facilities, a 10 MW PV facility and a 75 MW solar thermal steam generating facility, began commercial operation in 2010. The addition of these renewable energy facilities was made possible due to enabling legislation from the Florida Legislature in 2008. FPL remains strongly supportive of federal and/or state legislation that enables electric utilities to add renewable energy resources and authorize the utilities to recover appropriate costs for these resources. FPL is planning to introduce two new PV-based solar programs in 2014. These are discussed further in section III.F.4 of this chapter.

In regard to using natural gas more efficiently, FPL received approvals in 2008 from the FPSC to modernize the existing Cape Canaveral and Riviera Beach plant sites with new, highly efficient CC units that replace the former steam generating units on each of those sites. The Cape Canaveral modernization was commissioned on April 24, 2013 and the Riviera Beach modernization is projected to go in-service on/near the April 1, 2014 date this 2014 Site Plan is filed with the FPSC. On April 9th, 2012, FPL received FPSC approval to proceed with a similar modernization project at the Port Everglades site which is scheduled for completion in mid-2016. The modernization of the Port Everglades site will retain the capability of receiving water-borne delivery of oil as a backup fuel.

In regard to diversity in natural gas sourcing and delivery, in 2013 FPL was granted approval from the FPSC to build a new 3rd natural gas pipeline into Florida and FPL's service territory. The process to obtain approval for the new pipeline from the Federal Energy Regulatory Commission (FERC) is underway. The new pipeline will utilize a new route that will result in a more reliable, more economic, and more diverse natural gas supply for FPL's customers and the state of Florida.

In the future, FPL will continue to identify and evaluate alternatives that may maintain or enhance system fuel diversity. In this regard, FPL is maintaining the ability to utilize fuel oil at existing units that have that capability. For this purpose, FPL has installed electrostatic precipitators (ESPs) at its two 800 MW steam generating units at the Manatee site and at one of its two 800 MW steam generating units at the Martin site. FPL is in the process of installing ESPs on its remaining 800 MW steam generating unit at the Martin site. These installations will enable FPL to retain the ability to burn oil, as needed, at these sites while retaining the flexibility to use natural gas when economically attractive.

2. Maintaining a Balance Between Load and Generation in Southeastern Florida:

An imbalance has existed between regionally installed generation and regional peak load in Southeastern Florida. As a result of that imbalance, a significant amount of energy required in the Southeastern Florida region during peak periods is provided by operating less efficient generating units located in Southeastern Florida out of economic dispatch, by importing the energy through the transmission system from plants located outside the region, or by a combination of the two. FPL's prior planning work concluded that, as load inside the region grows, either additional installed generating capacity in this region, or additional installed transmission capacity capable of delivering more electricity from outside the region, would be required to address this imbalance.

Partly because of the lower transmission-related costs resulting from their location, four recent capacity addition decisions (Turkey Point Unit 5 and WCEC Units 1, 2, & 3) were determined to be the most cost-effective options to meet FPL's capacity needs in the near-term. In addition, FPL has added increased capacity at FPL's existing two nuclear units at Turkey Point as part of the previously mentioned nuclear capacity uprates project. The Port Everglades modernization project scheduled for completion in 2016 will also assist in addressing this imbalance. Adding the additional generation capacity through the projects mentioned above contributes to addressing the imbalance between generation, transmission capacity, and load in Southeastern Florida for approximately the remainder of this decade.

The planned addition of two new nuclear units at FPL's Turkey Point site, Turkey Point Unit 6 in 2022 and Turkey Point Unit 7 in 2023, will also address the imbalance issue for an additional period of time beginning in the next decade. Due to forecasted steadily increasing load in the Southeastern region, the Southeastern Florida imbalance issue will remain an important consideration in FPL's on-going resource planning work in future years.

3. Projections of Federal and State Energy Efficiency Codes and Standards:

As discussed in Chapter II, FPL's load forecast includes projected impacts from federal and state energy efficiency codes and standards. The magnitude of energy efficiency that is now projected to be delivered to FPL's customers through these codes and standards is significant.

In FPL's 2013 Site Plan, the projected cumulative Summer peak impact for the year 2022 from the codes and standards since 2005 was 2,898 MW compared to what the projected load would have been without the codes and standards. The current projection of cumulative Summer peak impact for the year 2023 from the codes and standards since 2005 is 3,477 MW.

In addition to lowering FPL's load forecast from what it otherwise would have been, and thus serving to lower FPL's projected resource needs, this projection of efficiency from the codes and standards also affects FPL's resource planning in another way. The projected impacts from the efficiency codes and standards lower the potential for utility DSM programs to deliver energy efficiency for the appliances and equipment that are directly addressed by the codes and standards. This effect is taken into account in FPL's proposed DSM Goals for the 2015 – 2024 time period and it is one reason why FPL's resource plan shows a diminished role for utility DSM for the years addressed by this 2014 Site Plan.

4. **Decline in the Projected Cost-Effectiveness of Utility DSM Measures and Programs:** There is another important reason why FPL's resource plan currently shows a diminished role for utility DSM: a decline in the projected cost-effectiveness of utility DSM measures and programs. The supporting testimony that FPL is filing in the DSM Goals proceeding discusses in detail the reasons for the declining cost-effectiveness of DSM. One portion of that discussion is summarized here for illustrative purposes.

The cost-effectiveness of DSM is driven in large part by the potential benefits that the kw (demand) reduction and kwh (energy) reduction characteristics of DSM programs are projected to provide. This discussion focuses solely on the current projection of potential benefits that DSM's kwh reductions can provide. At least three factors are each resulting in projections of lower kwh reduction-based benefits and thus projections of lower DSM cost-effectiveness.

The first factor is lower fuel costs. For example, comparing current fuel cost forecasts with those forecasted in 2009 – the year when FPL's DSM Goals were last set by the FPSC – shows that current forecasted fuel costs are now much lower than those forecasted in 2009, particularly in the near-term. This can be seen by comparing the 2009 and current forecasted costs ($/mmBTU) for natural gas for two specific years addressed in this Site Plan and which were addressed in the 2009 DSM goals-setting: 2015 and 2019:

Year	2009 Forecast	Current Forecast
2015	$9.64	$4.26
2019	$12.63	$6.15

As shown from these values, natural gas prices are currently forecast to be less than 50% of what they were forecast to be in 2009 when DSM goals were last set. Although lower forecasted natural gas costs are a very good thing for FPL's customers, lower fuel costs also result in lower potential fuel savings benefits from the kWh reductions of DSM measures. These lowered benefit values result in DSM being less cost-effective.

A second factor contributing to the decline in the cost-effectiveness of utility DSM is the steadily increasing efficiency with which FPL generates electricity. FPL's generating system has steadily gotten more efficient in regard to its ability to generate electricity using less fossil fuel. For example, FPL used 20% less fossil fuel to generate the same number of kwh in 2012 than it did in 2001. This is a very good thing for FPL's customers because it helps to significantly lower fuel costs.

The improvements in generating system efficiency affect DSM cost-effectiveness in much the same way that lower forecasted fuel costs do: both lower the fuel costs of energy delivered to FPL's customers. Therefore, the improvements in generating system efficiency further reduce the potential fuel savings benefits from the kWh reduction impacts of DSM, thus lowering potential DSM benefits and DSM cost-effectiveness.

A third factor for declining cost-effectiveness of utility DSM is due to significant changes in projected carbon dioxide (CO_2) compliance costs. For example, comparing CO_2 compliance forecasts with those forecasted in 2009 – the year when FPL's DSM Goals were last set by the FPSC – shows that current forecasted compliance costs are much lower than those forecasted in 2009, particularly in the near-term. This can be seen by comparing the 2009 and current forecasted costs ($/ton) for two specific years addressed in this Site Plan and which were addressed in the 2009 DSM goals-setting: 2015 and 2019:

Year	2009 Forecast	Current Forecast
2015	$17.00	$0.00
2019	$25.00	$0.00

(FPL's current forecast does not project non-zero CO_2 compliance costs until the year 2023.) While lower forecasted CO_2 compliance costs are again a good thing for FPL's customers, lower compliance costs also result in lower compliance cost savings benefits from the kWh reductions of DSM measures. These lower potential DSM benefits again result in lowering DSM cost-effectiveness.

Each of these three factors discussed above – lower forecasted fuel costs, greater efficiency in FPL's electricity generation, and lower forecasted CO_2 compliance costs – are good for FPL's customers because they will result in lower electric rates. Although good for FPL's customers, these factors also contribute to lowering the cost-effectiveness of utility DSM programs. Therefore, these factors (and other factors not discussed above), plus the growing impacts of energy efficiency codes and standards, lead to FPL's resource plan showing a diminished role for utility DSM.

5. **FPL's Increasing Dependence On DSM Resources to Maintain System Reliability:**

As discussed earlier in section III.A of this chapter, FPL's 2011, 2012, and 2013 Site Plans each projected that FPL's system was becoming increasingly dependent upon DSM resources to maintain system reliability. FPL's analyses of this projected trend showed that, from an operational perspective, there can be significant differences between resources plans on the peak day even though the resource plans have identical total reserve margins. For this reason, FPL has begun using a 10% minimum generation-only reserve margin (GRM) in its resource planning work to complement its existing 20% total reserve margin and 0.1 day/year LOLP reliability criteria. FPL will begin applying the GRM criterion in the year 2019.

6. **The Schedule for the New Turkey Point Nuclear Units 6 & 7:**

At the time the 2014 Site Plan is being finalized, the schedule for the project is under review. Several items will be considered that potentially influence the project schedule, including the Nuclear Regulatory Commission's (NRC's) schedule for reviewing the Combined Operating License Application (COLA), the impacts of the recently amended nuclear cost recovery clause (NCRC) statute, and the ongoing feasibility analyses that are part of the NCRC process.

7. **Environmental Regulation and/or Legislation:**

The seventh factor is environmental regulation. As developments occur in regard to either new environmental regulations, and/or in how environmental regulations are interpreted and applied, the potential exists for such developments to affect FPL's resource plan that is presented in this document. For example, FPL is aware of potential impacts to generating units of recent EPA changes to the National Ambient Air Quality Standards that include shorter duration 1-hour standards for nitrogen dioxide (NO_2) and sulfur dioxide (SO_2). As a consequence, FPL filed in mid-2013 for FPSC approval to recover costs through the environmental cost recovery clause for removing all of its existing gas turbines (GTs) and partially replacing that peaking unit capacity with new combustion turbines (CTs). Although FPL withdrew its filing in December 2014 pending further analyses including on-site monitoring, FPL believes that the results of the monitoring and analyses will require that the Broward GTs be replaced. Therefore, FPL is currently projecting the retirement of all GTs in Broward County; i.e., at its existing Lauderdale and Port Everglades plant sites (a decrease in generating capacity of 1,260 MW Summer), and the installation of 5 new 201 MW CTs at its existing Lauderdale plant site (an increase of 1,005 MW Summer), both by the end of 2018.

8. **Possible establishment of a Florida standard for renewable energy or clean energy:** Although no such legislation has been enacted to-date, Renewable Portfolio Standards (RPS) or Clean Energy Portfolio Standard (CPS) legislation, or other legislative initiatives regarding renewable or clean energy contributions, may occur in the future at either the state or national level. If such legislation is enacted, FPL would then determine what steps need to be taken to address the legislation.

Each of these 8 factors will continue to be examined in FPL's on-going resource planning work during the rest of 2014 and in future years.

III.D Demand Side Management (DSM)

FPL has sought out and implemented cost-effective DSM programs since 1978 and DSM has been a key focus of FPL's IRP process for decades. During that time FPL's DSM programs have included numerous energy efficiency and load management initiatives. FPL's DSM efforts through 2013 have resulted in a cumulative Summer peak reduction of approximately 4,753 MW (Summer) at the generator and an estimated cumulative energy saving of approximately 66,782 Gigawatt Hour (GWh) at the generator. After accounting for the 20% total reserve margin requirement, FPL's DSM efforts through 2013 have eliminated the need to construct the equivalent of approximately 14 new 400 MW power plants.

FPL has consistently been among the leading utilities nationally in DSM achievement. For example, according to the U.S. Department of Energy's 2012 data (the last year for which the DOE data was available at the time this Site Plan is being developed), FPL ranked # 2 nationally in cumulative DSM demand reduction. And, importantly, FPL has achieved these significant DSM accomplishments while minimizing the DSM-based impact on electric rates for all of its customers.

In 2014, new DSM Goals for the years 2015 through 2024 will be set for FPL by the FPSC. As part of this goals-setting process, FPL must propose new DSM Goals for this time period based on its most recent resource planning analyses. The results of those analyses are reflected in this 2014 Site Plan and FPL is filing its proposed new DSM Goals on April 2, 2014 (i.e., one day after the 2014 Site Plan is filed). As discussed in the previous section of this chapter, two factors have influenced the analyses that led to the amount of DSM that FPL is proposing as its new DSM Goals: (i) increased energy efficiency that will be delivered to FPL's customers through Federal and state energy efficiency codes and standards; and (ii) a decline in the projected cost-effectiveness of DSM measures.

Based on these factors and FPL's most recent resource planning analyses, FPL is proposing that its DSM Goals be set at 337 MW of Summer MW reduction. After accounting for the 20% total reserve margin requirements, this represents the elimination of the need to construct the equivalent of another 400 MW power plant. The resource plan presented in this 2014 Site Plan accounts for the proposed amount of annual DSM implementation through the year 2023 and the DSM contribution is shown in Schedules 7.1 and 7.2 that appear later in this chapter. The FPSC is expected to make its decision regarding what FPL's DSM Goals will be for 2015 through 2024 later this year.

III.E Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy to FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV bulk transmission lines that must be certified under the Transmission Line Siting Act.

Table III.E.1: List of Proposed Power Lines

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (KV)	(7) Capacity (MVA)
FPL	St. Johns 1/	Pringle	25	Dec – 18	230	759
FPL	Manatee 2/	Bob White	30	Dec – 14	230	1195

1/ Final order certifying the corridor was issued on April 21, 2006. This project is to be completed in two phases. Phase I consisted of 4 miles of new 230 kV line (Pringle to Pellicer) and was completed in May-2009. Phase II consists of 21 miles of new 230 kV line (St. Johns to Pellicer) and is scheduled to be completed by Dec-2018.
2/ Final order certifying the corridor was issued on November 6, 2008. This project consists of 30 miles of new 230 kV line (Manatee to Bob White) and is scheduled to be completed by Dec-2014

In addition, there will be transmission facilities needed to connect several of FPL's projected generating capacity additions to the system transmission grid. These transmission facilities (described on the following pages) are for the Port Everglades modernization, the planned Lauderdale gas turbine replacements, and the planned new nuclear capacity addition at the Turkey Point site from Turkey Point Units 6 & 7.[5] Please see discussion in the Turkey Point Preferred Site section, subsection r, of the possibility of a transmission corridor/land swap between FPL and the National Park Service. At the time the 2014 Site Plan is being prepared, no

[5] Please see discussion in the Turkey Point Preferred Site section, subsection r of the possibility of a transmission corridor/land sway between FPL and National Park Service.

site has been selected for the planned addition of a CC unit in 2019. Therefore, no transmission information for this new unit is presented.

II.E.1 Transmission Facilities for Port Everglades Next Generation Clean Energy Center (Modernization)

The work required to connect the Port Everglades Next Generation Clean Energy Center in 2016 to the FPL grid is projected to be:

I. Substation:

1. Construct two string busses to connect two combustion turbines (CT) to the Port Everglades 138 kV Substation.
2. Construct two string busses to connect one CT, and one steam turbine (ST) to the Port Everglades 230 kV Substation.
3. Add four main step-up transformers (3-450 MVA, 1- 580 MVA), one for each CT, and one for the ST.
4. Replace ten (10) 138 kV breakers.
5. Replace eight (8) 230 kV breakers.
6. At Port Everglades Switchyard replace twenty-two 138 kV disconnect switches. Also upgrade associated jumpers, bus work, and equipment connections.
7. Expand switchyard relay vault and add relays and other protective equipment.

II. Transmission:

1. Upgrade of existing transmission facilities:
   - An ampacity upgrade up to 1905 amps on the Port Everglades-Port Everglades Tap 138kV line section.
   - An ampacity upgrade up to 1905 amps on the Port Everglades Tap-Port Everglades Tap 2 138 kV line section.
   - An ampacity upgrade up to 1695 amps on the Port Everglades Tap 1-Dania 138 kV line section.
   - An ampacity upgrade up to 1695 amps on the Dania-Hollywood 138 kV line section.

III.E.2 Transmission Facilities for the Lauderdale GT Replacement Project

The work required to connect the five Lauderdale combustion turbines (CT) in 2018 to the FPL grid is projected to be:

I. Substation:

1. Construct a collector switchyard for the five (5) CTs at Lauderdale Plant.
2. Install five (5) main step-up transformers (5 - 320 MVA), one for each CT.
3. Construct one 230 kV collector buss to connect two (2) CT step-up transformers to collector switchyard.
4. Construct one 138 kV collector buss to connect two (2) CT step-up transformers to collector switchyard.
5. Construct Cable Termination Structures (CTS) in the collector switchyard and the Lauderdale 138 kV Substation to connect the 138 kV collector buss for the two CTs to the Lauderdale 138 kV Substation Outside Bus.
6. Construct CTS in the collector switchyard and the Lauderdale 138 kV Substation to connect the fifth CT to the Lauderdale 138 kV Substation Inside Bus.
7. Add relays and other protective equipment.

II. Transmission:

1. Construct overhead 230 kV string bus to connect the 230 kV collector buss to the Lauderdale 230 kV Substation Inside Bus.
2. Construct two (2) underground 138 kV cables connecting the collector switchyard to the Lauderdale Substation Inside and Outside Busses.

III.E.3 Transmission Facilities for Turkey Point Nuclear Unit 6

The work required to connect the Turkey Point Nuclear Unit 6 by Summer 2022 to the FPL grid is projected to be:

I. Substation:

1. Build new Clear Sky 500/230kV Switchyard with six (6) bays on the 230 kV section for generator main step-up transformer connection, reserve auxiliary transformer connections, four (4) 230 kV line terminals, two (2) autotransformers and two (2) 500 kV line terminals.
2. At Turkey Point Switchyard add a new bay to accommodate the Turkey Point-Clear Sky 230 kV line terminal.
3. At Pennsuco Substation install a fourth line terminal to accommodate the Pennsuco-Clear Sky 230 kV line by converting the ring bus to a breaker and a half scheme and adding four (4) 230 kV breakers.
4. At Davis Substation construct two (2) new 230kV line terminals for the Clear Sky-Davis 230 kV line and the Davis-Miami 230 kV line.
5. At Levee Substation expand 500 kV section to accommodate the two (2) Levee-Clear Sky 500 kV lines.
6. At Andytown Substation install two (2) 5-Ohm inductors combined with external shunt capacitors on the 230kV side of the 500/230 autotransformers (one per auto).
7. At Miami Substation expand the 230kV section to a double bus configuration and add a new 230kV line terminal for Davis line and replace one (1) autotransformer.
8. Breaker replacements:
   Flagami Substation – Replace five (5) 230 kV breakers and three (3) 138 kV breakers
   Miami Substation – Replace one (1) 230 kV breaker and four (4) 138 kV breakers
   Davis Substation - Replace two (2) 230 kV breakers

II. Transmission:

1. FPL will design and construct two (2) 500kV transmission lines from the new Clear Sky Substation to the existing FPL Levee 500kV Substation switchyard. The lines will be approximately 43 miles long.
2. Construct a new Clear Sky-Davis 230kV line (approximately 19 miles) with a rating of 2990 Amperes.
3. Construct a new Clear Sky-Pennsuco 230kV line (approximately 52 miles) with a rating of 2990 Amperes.
4. Construct a new Davis-Miami 230kV line (approximately 18 miles) with a rating of 2297 Amperes.
5. Construct a new Clear Sky-Turkey Point 230kV line (approximately 0.5 miles) with a rating of 2990 Amperes.

III.E.4 Transmission Facilities for Turkey Point Nuclear Unit 7

The work required to connect the Turkey Point Nuclear Unit 7 by Summer 2023 to the FPL grid is projected to be:

I. Substation:

1. At Gratigny Substation install a second 230/138 kV autotransformer with one (1) 230 kV breaker and one (1) 138 kV breaker.
2. At Davis Substation construct a switch-able inductor to be installed on the Davis-Miami 230 kV line.
3. At Flagami Substation install a small inductor on one end of the Flagami-Miami 230kV #2 circuit.
4. Breaker replacements:
   Dade Substation - Replace seven (7) 230 kV breakers
   Court Substation – Replace one (1) 138 kV breaker.

II. Transmission:

1. The transmission line facilities required for Turkey Point Unit 7 will be constructed with the transmission line facilities needed for Turkey Point Unit 6, as described above in section III. E.3.

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to effectively utilize renewable energy technologies to serve its customers. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various renewable energy technologies. For purposes of discussing FPL's renewable energy efforts in this document, those efforts will be placed into five categories.

Two of these categories are Supply-Side Efforts – Power Purchases, and Supply-Side Efforts – FPL Facilities. Since 2011, the energy (MWh) total output from these renewable energy sources has been greater than the energy produced from oil-fired generation. The renewable energy information is presented in Schedule 11.1, and the oil-based energy information is presented in Schedule 6.1 and in Schedule 11.1. Both of these schedules are presented at the end of this chapter.

1) <u>Early Research & Development Efforts:</u>

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970s in demonstrating the first residential photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities in Florida on both a daily and annual basis. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-kilowatt (kW) system was placed into operation in 1984. (The system was removed in 1990 at the conclusion of the PV testing to make room for substation expansion.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. This FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site became the home for PV capacity which was installed as a result of other FPL renewable energy initiatives.

2) <u>Demand Side & Customer Efforts:</u>

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers who chose solar water heaters. Before the program ended (due to the fact that it was no longer projected to be cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980s, FPL introduced another renewable energy program, FPL's Passive Home Program. This program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for six passive home designs with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code was one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the FPSC to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test were deemed to be solvable, particularly when new pools are constructed. However, challenges included the significant percentage of sites with unacceptable shading and various customer satisfaction issues.

FPL has since continued to analyze and promote the utilization of PV. These efforts have included PV research, development, and education, as well as development and implementation of the FPL Next Generation Solar Station Program. This initiative also delivers teacher training and curriculum that is tied to the Sunshine Teacher Standards in Florida. The program provides teacher grants to promote and fund projects in the classrooms.

In addition, FPL assists customers who are interested in installing PV equipment at their facilities. Consistent with Florida Administrative Code Rule 25-6.065, Interconnection and Net Metering of Customer-Owned Renewable Generation, FPL works with customers to interconnect these customer-owned PV systems. Through December 2013, approximately 2,565 customer systems (predominantly residential) have been interconnected.

As part of its 2009 DSM Goals decision, the FPSC imposed a requirement for Florida's investor-owned utilities to spend up to a set, not-to-exceed amount of money annually to facilitate demand side solar water heater and PV applications. FPL's not-to-exceed amount of money for these applications is approximately $15.5 million per year through 2014. In regard to this direction, FPL received approval from the FPSC in 2011 to initiate a solar pilot portfolio that consists of three PV-based programs and three solar water heating-based programs, plus Conservation Research and Development. These programs are currently projected to be offered through 2014. FPL's analyses of the results to-date from these programs shows that none of these programs are projected to be cost-effective using any of the three cost-effectiveness screening tests used by the State of Florida. The fate of these solar programs, including their potential replacement with new solar initiatives, will be determined later in 2014 as part of the FPSC's 2014 DSM Goals docket.

FPL has also been investigating fuel cell technologies through monitoring of industry trends, discussions with manufacturers, and direct field trials. From 2002 through the end of 2005, FPL conducted field trials and demonstration projects of Proton Exchange Membrane (PEM) fuel cells with the objectives of serving customer end-uses while evaluating the technical performance, reliability, economics, and relative readiness of the PEM technology. The demonstration projects were conducted in partnership with customers and included five locations. The research projects were useful to FPL in identifying specific issues that can occur in field applications and the current commercial viability of this technology. FPL will continue to monitor the progress of these technologies and conduct additional field evaluations as significant developments in fuel cell technologies occur.

3) Supply Side Efforts – Power Purchases:

FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy, and as-available energy, have been purchased by FPL from these types of facilities. (Please refer to Tables I.B.1, I.B.2, and I.C.1 in Chapter I).

FPL issued Renewable Requests for Proposals (RFPs) in 2007 and 2008 soliciting proposals to provide firm capacity and energy, and energy only, at or below avoided costs, from renewable generators. FPL also promptly responds to inquiries for information from prospective renewable energy suppliers either by e-mail or phone.

On April 22, 2013 in Order No. PSC-13-1064-PAA-EQ, the FPSC approved three 60 MW power purchase agreements with affiliates of U.S. EcoGen for biomass-fired renewable energy facilities. These facilities are expected to begin service in 2019, and to begin providing firm renewable energy and capacity to FPL's customers in 2021.

With regard to existing contracts that have recently ended, FPL and the Solid Waste Authority of Palm Beach (SWA) agreed to extend their contract that expired March 31, 2010 for a 20-

year term beginning in April 1, 2012 through April 1, 2032. However, the SWA refurbished their generating unit ahead of schedule and, as of January 2012, this unit began delivering firm capacity to FPL. In 2011, the FPSC approved a contract for an additional 70 MW between FPL and SWA for a new unit to be constructed and to begin delivering firm capacity and energy beginning on January 1, 2015. At the end of December 2011, the contract between FPL and Okeelanta (New Hope) expired. However, Okeelanta continues to deliver energy to FPL as an as-available, non-firm supplier of renewable energy.

4) Supply Side Efforts – FPL Facilities:

With regard to solar generating facilities, FPL has three such facilities: (i) a 75 MW steam generation solar thermal facility in Martin County (the Martin Next Generation Solar Energy Center); (ii) a 25 MW PV electric generation facility in DeSoto County (the DeSoto Next Generation Solar Energy Center); and (iii) a 10 MW PV electric generation facility in Brevard County at NASA's Kennedy Space Center (the Space Coast Next Generation Solar Energy Center). The DeSoto County project was completed in 2009 and the other two projects were completed in 2010. These three solar facilities were constructed in response to the Florida Legislature's House Bill 7135 which was signed into law by the Governor in June 2008.

House Bill 7135 was enacted to enable the development of clean, zero greenhouse gas emitting renewable generation in the State of Florida. Specifically, the bill authorized cost recovery for the first 110 MW of eligible renewable projects that had the proper land, zoning, and transmission rights in place. FPL's three solar projects met the specified criteria, and were granted approval for cost recovery in 2008. Each of the three solar facilities is discussed below.

a. The Martin Next Generation Solar Energy Center:

This facility began commercial operation in 2010 and provides 75 MW of solar thermal capacity in an innovative way that directly displaces fossil fuel usage on the FPL system. This facility consists of solar thermal technology which generates steam that is integrated into the existing steam cycle for the Martin Unit 8 natural gas-fired CC plant. This project is the first "hybrid" solar plant in the world, and, at the time the facility came in-service, was the second largest solar facility in the world and the largest solar plant of any kind in the U.S. outside of California.

b. The DeSoto Next Generation Solar Energy Center:

This PV facility began commercial operation in 2009 and provides 25 MW of non-firm capacity and energy, making it one of the largest PV facilities in the U.S. The facility utilizes a tracking PV array that is designed to follow the sun as it traverses across the sky.

c. <u>The Space Coast Next Generation Solar Energy Center:</u>

Located at the Kennedy Space Center, this facility is part of an innovative public/private partnership with NASA. This non-tracking PV facility began commercial operation in 2010 and provides 10 MW of non-firm capacity and energy.

At the time the 2014 Site Plan is being prepared, FPL considers the output from these renewable facilities to be "as available," non-firm energy only. This is due to several factors. First, the Martin solar thermal facility is a "fuel-substitute" facility, not a facility that provides additional capacity and energy. The solar thermal facility displaces the use of fossil fuel to produce steam on the FPL system when the solar thermal facility is operating. Second, in regard to the two PV facilities, the intermittent nature of the solar resource has made it difficult to-date to accurately determine what contribution the PV facilities at these specific locations can consistently make at FPL's late Summer afternoon and early Winter morning peak load hours. This is, in part, due to the fact that at least several years worth of Summer and Winter peak load periods are needed to accurately gauge the actual output of these PV facilities during system peak hours. FPL is now evaluating what portion, if any, of the PV facilities' output can be projected as firm capacity at the projected peak hours in FPL's resource planning work.

In addition to these three solar facilities, FPL is currently in the process of identifying other potential sites in the state for central station PV facilities. FPL is evaluating existing FPL generation sites along with potential Greenfield sites within FPL's service territory. These sites are discussed further in Chapter IV.

In regard to PV distributed generation (DG), FPL is planning to implement two PV DG solar programs in 2014. The first program is a voluntary customer participation program that will be pursued on a pilot basis. FPL will file for FPSC approval of this program near the April filing date of the 2014 Site Plan. The second program is designed to research the effects of increasing PV DG on the FPL system. This program will be introduced later in 2014. A brief description of the two programs follows.

d. <u>Voluntary, Community-based Solar Partnership Pilot Program</u>

FPL will be filing for FPSC approval of a tariff that provides customers an opportunity to make voluntary contributions toward the construction of PV facilities on a local level throughout FPL's service territory. The pilot program will provide all customers the opportunity to support the use of solar energy at a community scale, and is designed to be especially attractive for customers who do not wish, or are not able, to place solar equipment on their roof.

d. **C&I Solar Partnership Program:**

This is also a PV-focused research program that will be conducted in partnership with interested commercial and industrial (C&I) customers. Limited investments will be made in rooftop PV facilities in selected geographic areas in order to examine the effect of PV DG on FPL's distribution system. FPL will attempt to site these PV facilities in areas where PV DG already exists to better study feeder loading impacts. The PV facilities will be located on C&I customer property near the targeted feeders. The objective of the program is to gather data that will result in a better understanding of the effects of high PV DG penetrations on FPL's system.

5) **Ongoing Research & Development Efforts:**

FPL has developed alliances with several Florida universities to promote development of emerging technologies. For example, FPL has an alliance has been established with the newly formed Southeast National Marine Renewable Energy Center (SNMREC) at Florida Atlantic University (FAU), which will focus on the commercialization of ocean current, ocean thermal (i.e., energy conversion as well as cold water air conditioning), and hydrogen technologies. FPL has been supporting FAU with the discussions being held with the U.S. Department of the Interior's Minerals Bureau of Ocean Energy Management Regulation and Enforcement (BOEMRE). BOEMRE is working to establish the permitting process for ocean energy development on the outer continental shelf.

FPL has also developed a "Living Lab" to demonstrate FPL's solar energy commitment to employees and visitors at its Juno Beach office facility. To-date, FPL has installed five different PV arrays (different technologies) of rooftop PV totaling 24 kW at the Living Lab. In addition, two PV-covered parking structures with a total of approximately 90 kW of PV are in use at the FPL Juno office parking lot. Through these Living Lab projects, FPL is able to evaluate multiple solar technologies and applications for the purpose of developing a renewable business model resulting in the most cost-effective and reliable uses of solar energy for FPL's customers. FPL plans to continue to expand the Living Lab as new solar products come to market.

FPL has also been in discussions with several private companies on multiple emerging technology initiatives including ocean current, ocean thermal, hydrogen, fuel cell technology, biomass, biofuels, and energy storage

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980s, FPL relied primarily on a combination of fuel oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil–fired generation. In the early 1980s, FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership (20%) and additional purchases (30%) from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit 4 which began serving FPL's customers in 1991.

The trend since the early 1990s has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective CC generating units and the ready availability of natural gas. Most recently, FPL placed into commercial operation two new gas-fired CC units at the West County Energy Center (WCEC) site in 2009. A third new CC unit was added to the WCEC site in 2011. In addition, FPL finished modernization of its Cape Canaveral and Riviera Beach plant sites and is currently modernizing its existing Port Everglades plant site by removing the steam generating units previously on the site and replacing them with one highly efficient new CC unit. The new CC units at each of these three sites will provide highly efficient generation that will dramatically improve the efficiency of FPL's generation system in general and, more specifically, the efficiency at which natural gas is utilized.

In addition, FPL increased its utilization of nuclear energy through capacity uprates of its four existing nuclear units. With these uprates, more than 520 MW of additional nuclear capacity have been added to the FPL system. FPL is also pursuing plans to obtain licenses, permits, and approvals to construct and operate two new nuclear units at its existing Turkey Point site that, in total, would add approximately 2,200 MW of new nuclear generating capacity. The earliest dates by which these two new nuclear units could practically be deployed remain 2022 and 2023, respectively.

In regard to utilizing renewable energy, FPL has a 110 MW of solar generating capacity through a 75 MW solar thermal steam generating facility at FPL's existing Martin site, a 25 MW PV facility in DeSoto County, and a 10 MW PV facility in Brevard County. The DeSoto facility was placed into commercial operation in 2009. The other two solar facilities were placed into commercial operation in 2010.

FPL's future resource planning work will continue to focus on identifying and evaluating alternatives that would most cost-effectively maintain and/or enhance FPL's long-term fuel diversity. These fuel diverse alternatives may include: the purchase of power from renewable energy facilities, additional FPL-owned renewable energy facilities, obtaining additional access to diversified sources of natural gas such as liquefied natural gas (LNG) and natural gas from the Mid-Continent unconventional reserves, preserving FPL's ability to utilize fuel oil at its existing units, and increased utilization of nuclear energy. (As previously discussed, new advanced technology coal generating units are not currently considered as viable options in Florida in the ten-year reporting period of this document due, in part, to current projections of relatively small differences in fuel costs between coal and natural gas, significantly higher capital costs for coal units compared to CC units, greater efficiencies of CC units, and concerns over environmental regulations that would impact coal units more negatively than CC units.) The evaluation of the feasibility and cost-effectiveness of these, and other possible fuel diversity alternatives, will be part of FPL's on-going resource planning efforts.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2023 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

FPL's Fossil Fuel Cost Forecasts

Fossil fuel price forecasts, and the resulting projected price differentials between fuels, are major drivers used in evaluating alternatives for meeting future resource needs. FPL's forecasts are generally consistent with other published contemporary forecasts. An October 2013 fuel cost forecast was used in the analyses whose results led to the resource plan presented in this 2014 Site Plan.

Future oil and natural gas prices, and to a lesser extent, coal and petroleum coke prices, are inherently uncertain due to a significant number of unpredictable and uncontrollable drivers that influence the short- and long-term price of oil, natural gas, coal, and petroleum coke. These drivers include U.S. and worldwide demand, production capacity, economic growth, environmental legislation, and politics.

The inherent uncertainty and unpredictability in these factors today and tomorrow clearly underscores the need to develop a set of plausible oil, natural gas, and solid fuel (coal and petroleum coke) price scenarios that will bound a reasonable set of long-term price outcomes. In this light, FPL developed and utilized Low, Medium, and High price forecasts for fossil fuels in some of its 2013 and early 2014 resource planning work, particularly in regard to analyses conducted as part of the nuclear cost recovery filing work.

FPL's Medium price forecast methodology is consistent for oil and natural gas. For oil and natural gas commodity prices, FPL's Medium price forecast applies the following methodology:

a. For 2014 through 2015, the methodology used the October 7, 2013 forward curve for New York Harbor 1% sulfur heavy oil, U. S. Gulf Coast 1% sulfur heavy oil, ultra low sulfur diesel fuel oil, and Henry Hub natural gas commodity prices;

b. For the next two years (2016 and 2017), FPL used a 50/50 blend of the October 7, 2013 forward curve and the most current projections at the time from The PIRA Energy Group;

c. For the 2018 through 2030 period, FPL used the annual projections from The PIRA Energy Group; and,

d. For the period beyond 2030, FPL used the real rate of escalation from the Energy Information Administration (EIA). In addition to the development of oil and natural gas commodity prices, nominal price forecasts also were prepared for oil and natural gas transportation costs. The addition of commodity and transportation forecasts resulted in delivered price forecasts.

FPL's Medium price forecast methodology is also consistent for coal and petroleum coke prices. Coal and petroleum coke prices were based upon the following approach:

a. Delivered price forecasts for Central Appalachian (CAPP), Illinois Basin (IB), Powder River Basin (PRB), and South American coal and petroleum coke were provided by JD Energy; and,

b. The coal price forecast for SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements.

The development of FPL's Low and High price forecasts for oil, natural gas, coal, and petroleum coke prices were based on the historical volatility of the 12-month forward price, one year ahead. FPL developed these forecasts to account for the uncertainty which exists within each commodity as well as across commodities. These forecasts reflect a range of reasonable forecast outcomes.

3. Natural Gas Storage

FPL was under contract through March 2013 for 2 billion cubic feet (Bcf) of firm natural gas storage capacity in the Bay Gas storage facility located in Alabama. The Bay Gas storage facility is interconnected with the Florida Gas Transmission (FGT) pipeline. Starting on April 1, 2013, FPL entered into a new deal with Bay Gas Storage for one year for 2.5 billion cubic feet (Bcf) of firm natural gas storage capacity. In December 2013, FPL elected to extend this transaction for an additional three years which resulted in a lower annual cost for Bay Gas. FPL has predominately utilized natural gas storage to help mitigate gas supply problems caused by severe weather and/or infrastructure problems. Over the past several years, FPL has acquired upstream transportation capacity on several pipelines to help mitigate the risk of off-shore supply problems caused by severe weather in the Gulf of Mexico. While this transportation capacity has reduced FPL's off-shore exposure, a portion of FPL's supply portfolio remains tied to off-shore natural gas sources. Therefore, natural gas storage remains an important tool to help mitigate the risk of supply disruptions. For these reasons, FPL has typically maintained nearly full natural gas inventory during normal operations from June through November (hurricane season). From December through March, FPL typically maintains lower levels of natural gas inventory compared to Summer peak months.

As FPL's reliance on natural gas has increased, its ability to manage the daily "swings" that can occur on its system due to weather and unit availability changes has become more challenging, particularly from oversupply situations. Natural gas storage is a valuable tool to help manage the daily balancing of supply and demand. From a balancing perspective, injection and withdrawal rights associated with gas storage have become an increasingly important part of the evaluation of overall gas storage requirements.

As FPL's system grows to meet customer needs, it must maintain adequate gas storage capacity to continue to help mitigate supply and/or infrastructure problems and to provide FPL the ability to manage its supply and demand on a daily basis. FPL continues to evaluate its gas storage portfolio and is likely to subscribe for additional gas storage capacity to help increase reliability, provide the necessary flexibility to respond to demand changes, and diversify the overall portfolio.

4. Securing Additional Natural Gas:

The recent trend of increasing reliance upon natural gas to produce electricity for FPL's customers is projected to continue due to FPL's growing load. The addition of highly fuel-efficient CC units at Cape Canaveral and Riviera Beach due to completed modernization projects, and the on-going Port Everglades modernization project, will serve to reduce the growth in natural gas use from what it otherwise might have been due to the high fuel-efficiency levels of these new CC units. However, these efficiency gains do not fully offset the effects of FPL's growing load. Therefore, FPL will need to secure more natural gas supply and more firm gas transportation capacity in the future as fuel requirements dictate. The issue is how to secure these additional natural gas resources in a manner that is economical for FPL's customers and which maintains and/or enhances the reliability of natural gas supply and deliverability to FPL's generating units.

FPL has historically purchased the gas transportation capacity required for new natural gas supply from two existing natural gas pipeline companies. As more natural gas is delivered through these two pipelines, the impact of a supply disruption on either pipeline becomes more problematic. Therefore, FPL issued a Request for Proposals (RFP) in December 2012 for gas transportation capacity to meet FPL's system natural gas requirements beginning in 2017. The RFP encouraged bidders to propose new gas transportation infrastructure to meet Florida's growing need for natural gas. A third pipeline would have benefits for FPL and its customers by increasing the diversity of FPL's fuel supply sources, increasing the physical reliability of the pipeline delivery system, and enhancing competition among pipelines. The RFP process was completed in June 2013 and the winning bidders, Sabal Trail Transmission, LLC (Sabal Trail) and Florida Southeast Connection, LLC (FSC), have begun the Federal Energy Regulatory Commission approval process with a planned in-service date of May 2017. The contracts with Sabal Trail and FSC were reviewed by the FPSC and were approved for cost recovery in late 2013. The order approving this cost recovery became final in January 2014.

5. Nuclear Fuel Cost Forecast

This section reviews the various steps needed to fabricate nuclear fuel for delivery to the nuclear power plants, the method used to forecast the price for each step, and other comments regarding FPL's nuclear fuel cost forecast.

a) Steps Required for Nuclear Fuel to be delivered to FPL's Plants

Four separate steps are required before nuclear fuel can be used in a commercial nuclear power reactor. These steps are summarized below.

(1) Mining: Uranium is produced in many countries such as Canada, Australia, Kazakhstan, and the United States. During the first step, uranium is mined from the ground using techniques such as open pit mining, underground mining, in-situ leaching operations, or production as a by-product from other mining operations, such as gold, copper, or phosphate rocks. The product from this first step is the raw uranium delivered as an oxide, U_3O_8 (sometimes referred to as yellowcake).

(2) Conversion: During the second step, the U_3O_8 is chemically converted into UF_6 which, when heated, changes into a gaseous state. This second step further removes any chemical impurities and serves as preparation for the third step, which requires uranium to be in a gaseous state.

(3) Enrichment: The third step is called enrichment. Natural uranium contains 0.711% of uranium at an atomic mass of 235 (U-235) and 99.289% of uranium at an atomic mass of 238 (U-238). FPL's nuclear reactors use uranium with a higher percentage of up to almost five percent (5%) of U-235 atoms. Because natural uranium does not contain a sufficient amount of U-235, the third step increases the percentage amount of U-235 from 0.711% to a level specified when designing the reactor core (typically in a range from approximately 2.2% to as high as 4.95%). The output of this enrichment process is enriched uranium in the form of UF6.

(4) Fabrication: During the last step, fuel fabrication, the enriched UF6 is changed to a UO2 powder, pressed into pellets, and fed into tubes, which are sealed and bundled together into fuel assemblies. These fuel assemblies are then delivered to the plant site for insertion in a reactor.

Like other utilities, FPL has purchased raw uranium and the other components of the nuclear fuel cycle separately from numerous suppliers from different countries.

b) Price Forecasts for Each Step

(1) Mining: The impact of the earthquake and tsunami that struck the Fukushima nuclear complex in Japan in March 2011 is still being felt in the uranium market. Current demand has declined and several of the production facilities have announced delays. Factors of importance are:

- Hedge funds are still very active in the market. This causes more speculative demand that is not tied to market fundamentals and causes the market price to move up or down just based on news that might affect future demand.
- Some of the uranium inventory from the U.S. Department of Energy (DOE) is finding its way into the market periodically to fund cleanup of certain Department of Energy facilities.
- Although a limited number of new nuclear units are scheduled to start production in the U.S. during the next 5 to 10 years, other countries, more specifically China, have announced an increase in construction of new units which may cause uranium prices to trend up in the near future.

Over a 10-year horizon, FPL expects the market to be more consistent with market fundamentals. The supply picture is more stable, with laws enacted to resolve the import of Russian-enriched uranium, by allowing some imports of Russian-enriched uranium to meet about 20-25% of needs for currently operating units, but with no restriction on the first core for new units and no restrictions after 2020. New and current uranium production facilities continue to add capacity to meet demands. Actual demand tends to grow over time because of the long lead time to build nuclear units. However, FPL cannot discount the possibility of future periodic sharp increase in prices, but believes such occurrences will likely be temporary in nature.

(2) Conversion: The conversion market is also in a state of flux due to the Fukushima events. Planned production after 2016 is currently forecasted to be insufficient to meet the higher demand scenario, but it is projected to be sufficient to meet most reference case scenarios. As with additional raw uranium production, supply will expand beyond current level once more firm commitments are made including commitments to build new nuclear units. FPL expects long term price stability for conversion services to support world demand.

(3) Enrichment: As a result of the Fukushima events in March 2011, the near-term price of enrichment services has been declining for the last three years. However, plans for construction of several new facilities that were expected to come on-line in the next few years have been delayed. Also, some of the existing high operating cost diffusion plants have shut down. As with supply for the other steps of the nuclear fuel cycle, expansion of future capacity is feasible within the lead time for constructing new nuclear units and any other projected increase in demand. Meanwhile, world supply and demand will continue to be balanced such that FPL expects adequate supply of enrichment services. The current supply/demand profile will most likely result in the price of enrichment services remaining stable or declining for the next few years before starting to increase.

(4) Fabrication: Because the nuclear fuel fabrication process is highly regulated by the Nuclear Regulatory Commission (NRC), not all production facilities can qualify as suppliers to nuclear reactors in the U.S. Although world supply and demand is expected to show significant excess capacity for the foreseeable future, the gap is not as wide for U.S. supply and demand. The supply for the U.S. market is expected to be sufficient to meet U.S. demand for the foreseeable future.

c) Other Comments Regarding FPL's Nuclear Fuel Cost Forecast

FPL's nuclear fuel price forecasts are the result of FPL's analysis based on inputs from various nuclear fuel market expert reports and studies. The calculations for the nuclear fuel cost forecasts used in FPL's 2013 and early 2014 resource planning work were performed consistent with the method then used for FPL's Fuel Clause filings, including the assumption of refueling outages every 18 months and plant operation at power uprate levels. The costs for each step to fabricate the nuclear fuels were added to come up with the total costs of the fresh fuel to be loaded at each refueling (acquisition costs). The acquisition cost for each group of fresh fuel assemblies were then amortized over the energy produced by each group of fuel assemblies. FPL also added 1 mill per kilowatt hour net to reflect payment to DOE for spent fuel disposal.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Vero Beach Combined Cycle Capacity

(2) **Capacity**
a. Summer 46 MW
b. Winter 44 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: Not Applicable - See Note 1 below.
b. Commercial In-service date: 2015

(5) **Fuel**
a. Primary Fuel Gas
b. Alternate Fuel Oil

(6) **Air Pollution and Control Strategy:** N/A

(7) **Cooling Method:** Once-through cooling water

(8) **Total Site Area:** 16 Acres

(9) **Construction Status:** See note 1 below

(10) **Certification Status:** See note 1 below

(11) **Status with Federal Agencies:** See note 1 below

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	20.5%	
Forced Outage Factor (FOF):	0.0%	
Equivalent Availability Factor (EAF):	72.5%	
Resulting Capacity Factor (%):	3.88%	
Average Net Operating Heat Rate (ANOHR):	9,397	Btu/kWh
Base Operation 75F,100%		

(13) **Projected Unit Financial Data**

Book Life (Years):	TBD	years
Total Installed Cost ($/kW):	Not Applicable	
Direct Construction Cost ($/kW):	Not Applicable	
AFUDC Amount ($/kW):	Not Applicable	
Escalation ($/kW):	Not Applicable	
Fixed O&M ($/kW-Yr): ($)	Not Applicable	
Variable O&M ($/MWH): ($)	Not Applicable	
K Factor:	Not Applicable	

NOTE 1: The combined cycle capacity consists of two existing units. This existing unit is being acquired by FPL as part of the arrangement for FPL to serve Vero Beach's load beginning in January 2015. FPL is also taking ownership of three steam units.The three steam units will be retired as soon as they aquired. FPL plans to retire the CC unit at the end of 2017.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Port Everglades Next Generation Clean Energy Center

(2) **Capacity**
a. Summer 1,237 MW
b. Winter 1,429 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2014
b. Commercial In-service date: 2016

(5) **Fuel**
a. Primary Fuel — Natural Gas
b. Alternate Fuel — Ultra-low sulfur distillate

(6) **Air Pollution and Control Strategy:** Dry Low No_x Burners, SCR, Natural Gas, 0.0015% S. Distillate and Water Injection on Distillate

(7) **Cooling Method:** Once-through cooling water

(8) **Total Site Area:** Existing Site Acres

(9) **Construction Status:** U (Under construction, less than or equal to 50% complete)

(10) **Certification Status:** ---

(11) **Status with Federal Agencies:** ---

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	3.5%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	95.4%	
Resulting Capacity Factor (%):	Approx. 90%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,330	Btu/kWh
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	30	years
Total Installed Cost (2016 $/kW):	928	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):	87	
Escalation ($/kW):		
Fixed O&M ($/kW-Yr): (2016 $)	30.00	
Variable O&M ($/MWH): (2016 $)	0.10	
K Factor:	1.51	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement.

NOTE: Total installed cost includes gas expansion, transmission interconnection and integration, escalation, and AFUDC. Demolition costs of existing plant are not included.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Lauderdale CT's (5 CTs will be added)

(2) **Capacity (for each CT)**

a. Summer	201	MW
b. Winter	223	MW

(3) **Technology Type:** Combustion Turbine

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2017
b. Commercial In-service date: 2018

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Ultra-low sulfur distillate

(6) **Air Pollution and Control Strategy:** Dry Low NO_x Burners, SCR, Natural Gas, 0.0015% S. Distillate and Water Injection on Distillate

(7) **Cooling Method:** Water to Air Heat Exchangers

(8) **Total Site Area:** Existing Site Acres

(9) **Construction Status:** P (Planned Unit)

(10) **Certification Status:** ---

(11) **Status with Federal Agencies:** ---

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	1.6%	
Forced Outage Factor (FOF):	1.0%	
Equivalent Availability Factor (EAF):	97.4%	
Resulting Capacity Factor (%):	3%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	10,057	Btu/kWh
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	30	years
Total Installed Cost (2018 $/kW):	547	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):	56	
Escalation ($/kW):		
Fixed O&M ($/kW-Yr): (2018 $)	17.63	
Variable O&M ($/MWH): (2018 $)	0.07	
K Factor:	1.59	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement.

NOTE: Total installed cost includes transmission interconnection and integration, escalation, and AFUDC. Demolition costs of existing GTs are not included.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Unsited 3x1 CC

(2) **Capacity**

a. Summer 1,269 MW

b. Winter 1,429 MW

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2017
b. Commercial In-service date: 2019

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Ultra-low sulfur distillate

(6) **Air Pollution and Control Strategy:** Dry Low NO_x Burners, SCR, Natural Gas, 0.0015% S. Distillate and Water Injection on Distillate

(7) **Cooling Method:** Once-through cooling water

(8) **Total Site Area:** TBD Acres

(9) **Construction Status:** P (Planned Unit)

(10) **Certification Status:** ---

(11) **Status with Federal Agencies:** ---

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	3.5%	
Forced Outage Factor (FOF):	1.1%	
Equivalent Availability Factor (EAF):	95.4%	
Resulting Capacity Factor (%):	Approx. 90%	(First Full Year Base Operation)
Average Net Operating Heat Rate (ANOHR):	6,334	Btu/kWh
Base Operation 75F,100%		

(13) **Projected Unit Financial Data *,****

Book Life (Years):	30	years
Total Installed Cost (2019 $/kW):	968	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):	95	
Escalation ($/kW):	872.79	
Fixed O&M ($/kW-Yr): (2019 $)	22.25	
Variable O&M ($/MWH): (2019 $)	0.72	
K Factor:	1.51	

* $/kW values are based on Summer capacity.
** Fixed O&M cost includes capital replacement.

NOTE: Total installed cost includes gas lateral, transmission interconnection and integration, escalation, and AFUDC.

Schedule 9

Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Turkey Point Nuclear Unit 6

(2) **Capacity**

a. Summer	1,100	MW
b. Winter	1,100	MW

(3) **Technology Type:** Nuclear

(4) **Anticipated Construction Timing**

a. Field construction start-date:	2015
b. Commercial In-service date:	2022

(5) **Fuel**

a. Primary Fuel	Uranium Dioxide
b. Alternate Fuel	N/A

(6) **Air Pollution and Control Strategy:** N/A

(7) **Cooling Method:** Mechanical Draft Cooling Towers

(8) **Total Site Area:** 211 Acres

(9) **Construction Status:** L (Regulatory approval pending.Not under construction)

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Vero Beach Existing Combined Cycle Capacity

The Vero Beach existing combined cycle capacity that FPL is projected to take ownership of starting January 1, 2015 does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Port Everglades Next Generation Clean Energy Center

The Port Everglades Next Generation Clean Energy Center which will result from the modernization of the Port Everglades power plant site does not require any “new” transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Lauderdale Combustion Turbine Project

The Lauderdale Combustion Turbine (CT) project, which will result in the retirement of 36 aero-derivative combustion gas turbines at the Lauderdale and Port Everglades plant sites, and their replacement with 5 simple-cycle combustion turbines at the Lauderdale site, does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Unsited Combined Cycle in 2019

No projection of a new transmission line(s) can be made until a site is selected for this unit.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point Nuclear Unit 6

The Turkey Point New Nuclear Project starting with the addition of Turkey Point Unit 6 will require a new substation and five new transmission lines terminating at existing substations.

(1)	Point of Origin and Termination:	New Clear Sky Substation – Levee Substation
(2)	Number of Lines:	2
(3)	Right-of-way	FPL Owned
(4)	Line Length:	43 miles
(5)	Voltage:	500 kV
(6)	Anticipated Construction Timing:	Start date: TBD End date: TBD
(7)	Anticipated Capital Investment: (Trans.and Sub.)	$ TBD
(8)	Substations:	New Clear Sky Substation and Levee Substation
(9)	Participation with Other Utilities:	None

(1)	Point of Origin and Termination:	New Clear Sky Substation – Pennsuco Substation
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	52 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBD End date: TBD
(7)	Anticipated Capital Investment: (Trans.and Sub.)	$ TBD
(8)	Substations:	New Clear Sky Substation and Pennsuco Substation
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point Nuclear Unit 6 (continued)

(1)	Point of Origin and Termination:	New Clear Sky Substation – Davis Substation
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	19 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBD End date: TBD
(7)	Anticipated Capital Investment: (Trans.and Sub.)	$ TBD
(8)	Substations:	New Clear Sky Substation and Davis Substation
(9)	Participation with Other Utilities:	None

(1)	Point of Origin and Termination:	Davis Substation – Miami Substation
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	18 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBD End date: TBD
(7)	Anticipated Capital Investment: (Trans.and Sub.)	$ TBD
(8)	Substations:	Davis Substation and Miami Substation
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point Nuclear Unit 6 (continued)

(1)	Point of Origin and Termination:	New Clear Sky Substation – Turkey Point Substation
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	0.5 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBD End date: TBD
(7)	Anticipated Capital Investment: (Trans.and Sub.)	$ TBD
(8)	Substations:	New Clear Sky Substation and Turkey Point Substation
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Turkey Point Nuclear Unit 7

The transmission lines required for Turkey Point Unit 7 will be constructed with Turkey Point Unit 6 and are listed in the Schedule 10 for Turkey Point Nuclear Unit 6.

Schedule 11.1

Existing FIRM and NON-FIRM Capacity and Energy by Primary Fuel Type
Actuals for the Year 2013

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
		Net (MW) Capability				**NEL**	**Fuel Mix**
	Generation by Primary Fuel	**Summer (MW)**	**Summer (%)**	**Winter (MW)**	**Winter (%)**	**GWh (2)**	**%**
(1)	Coal	897	3.4%	911	3.3%	5,981	5.4%
(2)	Nuclear	3,453	13.2%	3,550	12.8%	25,243	22.6%

(12)	***Total :***	*26,218.0*	*100.0%*	*27,694.0*	*100.0%*	*111,655*	*100.0%*

Note:
(1) FPL Existing Units Total values on row (7), columns (2) and (4), match the System Firm Generating Capacity values found on Schedule 1 for Summer and Winter.
(2) Net Energy for Load GWh values on row (12), column (6), matches Schedule 6.1 value for 2013.

Schedule 11.2

Existing NON-FIRM Self-Service Renewable Generation Facilities
Actuals for the Year 2013

(1)	(2)	(3)	(4)	(5)	(6) = (3)+(4)-(5)
Type of Facility	Installed Capacity DC (MW)	Renewable Projected Annual Output (MWh)	Annual Energy Purchased from FPL (MWh)	Annual Energy Sold to FPL (MWh)	Projected Annual Energy Used by Customers
Customer-Owned Renewable Generation (0 kW to 10 kW)	12.86	16,142	111,831	465	127,508
Customer-Owned Renewable Generation (> 10 kW to 100 kW)	6.69	8,758	197,171	376	205,553
Customer-Owned Renewable Generation (> 100 kW - 2 MW)	7.94	10,475	62,050	177	72,348
	27.49	35,375	371,052	1,018	405,409

Notes:

(1) There were 2,565 customers with renewable generation facilities interconnected with FPL on December 31, 2013.
(2) The Installed Capacity value is the sum of the nameplate ratings (DC MW) for all of the customer-owned renewable generation facilities connected as of Dec. 31,2013. One system does not have a DC rating. The AC valued of 0.75 MW was included in the (> 100 - 2 MW) row.
(3) The Projected Annual Output value is based on NREL's PV Watts 1 program and the Installed Capacity value in column (2), adjusted for the date when each facility was installed and assuming each facility operated as planned.
(4) The Annual Energy Purchased from FPL is an actual value from FPL's metered data for 2013.
(5) The Annual Energy Sold to FPL is an actual value from FPL's metered data for 2013.
(6) The Projected Annual Energy Used by Customers is a projected value that equals:
(Renewable Projected Annual output + Annual Energy Purchased) minus the Annual Energy Sold to FPL.

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

Florida is a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered or threatened plant and animal species. Florida's residents, wildlife, and ecosystems require the same air, land, and water resources that are necessary to meet the demand for the generation, transmission, and distribution of electricity. The general public has an expectation that a large corporation, such as FPL, will conduct their business in an environmentally responsible manner that minimizes impacts to the natural environment.

FPL has been recognized for many years as one of the leaders among electric utilities for its commitment to the environment. Being responsible stewards of the environment is ingrained in FPL's corporate culture. FPL has one of the lowest emissions profiles among U.S. utilities and in 2013 its carbon dioxide (CO_2) emission rate was 35% lower (better) than the industry average.

FPL's environmental leadership and that of its parent company, NextEra Energy, Inc., has been heralded by many outside organizations as demonstrated by a few recent examples.

FPL's responsible tree care practices across its 35-county service area have been recognized for almost a decade. FPL has been the recipient of the Tree Line USA award annually from 2003 - 2013. This award is sponsored by the Arbor Day Foundation in cooperation with the National Association of State Foresters. The recognition is given to utilities that demonstrate quality tree care practices, annual worker training, and public education programs.

In 2013, FPL continued to support the Loggerhead Marinelife Center with a $21,500 donation toward the acquisition of a larger tank to assist in sea turtle rehabilitation. Two FPL employees serve as members of the Loggerhead Marinelife Center and are committed to its success. In addition, through a "Power to Care" charity event an additional $500 was collected by FPL staff and given to the Center. In past years, FPL has won the Loggerhead Marinelife Center's "Blue Business of the Year" award, which is given to those who are leading the way in raising awareness about, and have made significant contributions to improve and protect, South Florida's oceans, beaches, and wildlife. The award recognized FPL's protection and conservation of the endangered Florida manatee and the fostering of public and employee education and support.

FPL employees serve as board members for many organizations that focus on environmental restoration, preservation, and stewardship. A partial list of these organizations includes: Audubon Florida, the Everglades Foundation, the Arthur R. Marshall Foundation, The Nature Conservancy, and the Palm Beach Zoo.

IV.B FPL's Environmental Statement

At FPL and its parent company, NextEra Energy, Inc., we are committed to being an industry leader in environmental protection and stewardship, not only because it makes business sense, but because it is the right thing to do. Our commitment to compliance, conservation, communication, and continuous improvement fosters a culture of environmental excellence and drives the sustainable management of our business planning, operations, and daily work.

In accordance with our commitments to environmental protection and stewardship, FPL and NextEra Energy, Inc. endeavor to:

Comply

- Comply with all applicable environmental laws, regulations, and permits
- Proactively identify environmental risks and take action to mitigate those risks
- Pursue opportunities to exceed environmental standards
- Participate in the legislative and regulatory process to develop environmental laws, regulations, and policies that are technically sound and economically feasible
- Design, construct, operate, and maintain our facilities in an environmentally sound and responsible manner

Conserve

- Prevent pollution, minimize waste, and conserve natural resources
- Avoid, minimize, and/or mitigate impacts to habitat and wildlife
- Promote the efficient use of energy, both within our company and in our communities

Communicate

- Communicate this policy to all employees and publish it on the corporate website
- Invest in environmental training and awareness to achieve a corporate culture of environmental excellence
- Maintain an open dialogue with stakeholders on environmental matters and performance

Continuously Improve

- Establish, monitor, and report progress toward environmental targets
- Review and update this policy on a regular basis
- Drive continuous improvement through ongoing evaluations of our environmental management system to incorporate lessons learned and best practices.

This statement was updated in 2013 by FPL's parent company, NextEra Energy, Inc. to reflect changing expectations and ensure that employees are doing the utmost to protect the environment. FPL complies with all environmental laws, regulations, and permit requirements. FPL designs, constructs, and operates its facilities in an environmentally sound and responsible manner. It also responds immediately and effectively to any known environmental hazards or non-compliance situations. FPL's commitment to the environment does not end there. It proactively pursue opportunities to exceed current environmental standards, including reducing waste and emission of pollutants, recycling materials, and conserving natural resources throughout its operations and day-to-day work activities. FPL also encourages the efficient use of energy, both within the Company and in communities served by FPL. These actions are just a few examples of how FPL is committed to the environment.

To ensure that FPL is adhering to its environmental commitment, it has developed rigorous environmental governance procedures and programs. These include its Environmental Assurance Program and Corporate Environmental Governance Council. Through these programs, FPL conducts periodic environmental self-evaluations to verify that its operations are in compliance with environmental laws, regulations, and permit requirements. Regular evaluations also help identify best practices and opportunities for improvement.

IV.C Environmental Management

In order to successfully implement the Environmental Statement, FPL has developed a robust Environmental Management System program to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program. Other components of the system include: executive management support and commitment, a dedicated environmental corporate governance program, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident and/or emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

As part of its commitment to excellence and continuous improvement, FPL began implementing an enhanced environmental data management information system (EDMIS) in 2013. Environmental data management software systems are increasingly viewed as an industry best-management practice to ensure environmental compliance. FPL's top goals for this project are to: 1) improve the flow of environmental data between site operations and corporate services to ensure compliance, and 2) improve operating efficiencies. In addition, the EDMIS will help standardize environmental data collection, thus improving external reporting to the public.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities that are designed to evaluate environmental performance, verify compliance with corporate policy as well as legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and FPL policies. In addition to FPL facility audits, the Environmental Assurance Program performs audits of third-party vendors used for recycling and/or disposal of waste generated by FPL operations. Vendor audits provide information used for selecting candidates or incumbent vendors for disposal and recycling needs.

FPL has also implemented a Corporate Environmental Governance System, in which quarterly reviews are performed by each business unit deemed to have significant environmental exposures. Quarterly reviews evaluate operations for potential environmental risks and consistency with the company's Environmental Policy. Items tracked during the quarterly reviews include processes for the identification and management of environmental risks, metrics, and indicators and progress / changes since the most recent review.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2013 environmental outreach activities are summarized in Table IV.E.1.

Table IV.E.1: 2013 FPL Environmental Outreach Activities

Activity	Count (#)
Visitors to FPL's Energy Encounter at St. Lucie	2,900
Visitors to Manatee Park, Ft. Myers	>210,000
Number of website visits to FPL's Environmental & Corporate Responsibility Websites	245,630
Visitors to Barley Barber Swamp (Treasured Lands Partnership)	1,492
Martin Energy Center Solar Tours	~850
Solar Schools Program (# of schools actively generating)	24 schools 5 demo sites An additional 67 schools will come online by the end of 2014

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified six (6) Preferred Sites and four (4) Potential Sites for future generation additions. Preferred Sites are those locations where FPL has conducted significant reviews and has either taken action, is currently committed to take action, or is likely to take action, to site new generating capacity. Potential Sites are those sites that have attributes that support the siting of generation and are under consideration as a location for future generation. Some of these sites are currently in use as existing generation sites and some are not. The identification of a Potential Site does not indicate that FPL has made a definitive decision to pursue generation (or generation expansion or modernization in the case of an existing generation site) at that location, nor does this designation indicate that the size or technology of a generator has been determined. Analyses of any modernization candidates would include evaluation of numerous factors including: fuel delivery, transmission, permitting, etc. The Preferred Sites and Potential Sites are discussed in separate sections below.

IV.F.1 Preferred Sites

The modernization of FPL's Riviera Beach site was scheduled to be completed on/near April 1, 2014 (the filing date for this 2014 Site Plan). Therefore, the Riviera Beach modernization is not discussed further in this chapter. FPL currently has identified six (6) Preferred Sites. Four of these are existing plant sites: Port Everglades, Lauderdale, Putnam and Turkey Point; two of these would be new plant sites: Hendry County and Northeast (NE) Okeechobee County.

The Port Everglades site is a location where modernization work, to replace the former steam generating units with new combined cycle (CC) technology, is in progress. The modernization work is scheduled to be completed in mid-2016. The existing gas turbines (GTs) at the Port Everglades and the Lauderdale sites are projected to be removed by the end of 2018. Five new combustion turbines (CTs) are projected to be added at the Lauderdale site by the end of 2018 to partially replace the capacity from existing GTs at Port Everglades and at the Lauderdale sites. These actions will aid in addressing compliance with new air emissions standards. The Hendry County, NE Okeechobee County, and Putnam sites are the likely next locations for new CC units after the Port Everglades and Lauderdale projects mentioned above have been completed. In addition, the Hendry County and Okeechobee County sites are also likely sites for new photovoltaic (PV) facilities.

In regard to the Turkey Point site, the nuclear capacity uprate project was successfully completed in 2013. The new Turkey Point nuclear Units 6 & 7 are currently projected to come in-service in 2022 and 2023, respectively.

The first two Preferred Sites discussed below are in general chronological order with respect to when the capacity additions are projected to occur. The remaining four Preferred Sites are discussed in alphabetical order.

Preferred Site # 1: Port Everglades Plant, Broward County

This site is located on the existing FPL Port Everglades Plant property within the City of Hollywood, Broward County. The site is surrounded by the Port of Port Everglades. The site has barge access via the Port of Port Everglades. A rail line is located near the plant.

The previous site generating capacity was made up of two 200 MW (approximate) steam generating units (Units 1 & 2) and two 400 MW (approximate) steam generating units (Units 3 & 4). The four units have been taken out of service and dismantled as part of the modernization of the plant site.

The Port Everglades Plant site has been listed as a Preferred or Potential Site in previous FPL Site Plans for both CC and CT generation options. On April 9, 2012, the FPSC issued the final need order for the modernization of the existing Port Everglades Plant. As a result of the modernization of the site, the new generating unit - to be renamed the Port Everglades Next Generation Clean Energy Center (PEEC) – will replace the existing steam generating units with modern, highly efficient, lower-emission next-generation advanced CC technology. The existing four steam units have been removed from the site and will be replaced by a single new CC unit.

a. U.S. Geological Survey (USGS) Map

A USGS map of the PEEC site is found at the end of this chapter.

b. Proposed Facilities Layout

A general layout of the PEEC generating facilities is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing Port Everglades Plant formerly consisted of two 200 MW (approximate) and two 400 MW (approximate) generating units with conventional dual-fuel fired steam boilers and steam turbine units. These generating units have now been removed as part of the modernization project. The plant site includes minimal vegetation. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the site is comprised of facilities related to electric power generation for the former Port Everglades Plant generating units. The site is located adjacent to the Intracoastal Waterway. The site provides warm water as required for manatees pursuant to the facility's Manatee Protection Plan.

2. Listed Species

No adverse impacts to federally or state-listed terrestrial plants and animals are expected in association with construction at the site, due to the existing developed nature of the site and lack of suitable onsite habitat for listed species. The warm water discharges from the plant attract manatees, an endangered species. FPL continues to work closely with state and federal wildlife agencies to ensure protection of the manatees during the modernization process and upon operation of the new plant. FPL plans to install a temporary heating system to provide warm water for manatees as required pursuant to the facility's Manatee Protection Plan. FPL also anticipates complying with other manatee-related conditions of certification to ensure the protection of the manatees during the modernization work and during future operations of PEEC.

3. Natural Resources of Regional Significance Status

The construction and operation of a natural gas-fired CC generating facility at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to replace the former units (Units 1 through 4) with one new approximately 1,237 MW (Summer) unit consisting of three new CTs, three new heat recovery steam generators (HRSG), and a new steam turbine. The new CC unit is projected to be in service in mid-2016. Natural gas delivered via an existing pipeline is the primary fuel type for the unit with ultra-low sulfur light fuel oil serving as a backup fuel.

In addition, all of the existing GTs at the Port Everglades site are projected to be removed by the end of 2018.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is a combination of "Electrical Generating Facility" and "Utilities Use". A land use map of the site and adjacent areas is also found at the end of this chapter.

h. Site Selection Criteria Process

The Port Everglades site has been selected for modernization due to consideration of various factors including system load, ability to provide generation in the Miami-Dade/Broward region to help balance load and generation in the region, and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. However, there are environmental benefits of replacing the former steam units with a new CC unit including a significant reduction in system air emissions, improved aesthetics at the site, and continued warm water discharge for the manatees as required pursuant to the facility's Manatee Protection Plan. Further, modernizing this existing facility reduces the impact on natural resources by not requiring new land or new water resources.

i. Water Resources

Water from the Intracoastal Waterway via the Port of Port Everglades Slip No. 3 is currently used for once-through cooling water supply. The new plant will utilize portions of the existing once-through cooling water intake and discharge structures. Process and potable water for the modernized plant will come from the existing City of Ft. Lauderdale potable water supply.

j. Geological Features of Site and Adjacent Areas

FPL's Port Everglades Plant site is underlain by the surficial aquifer system. The surficial aquifer system in eastern Broward County is primarily composed of sand, sandstone, shell, silt, calcareous clay (marl), and limestone deposited during the Pleistocene and Pliocene ages. The sediments forming the aquifer system are the Pamlico Sand, Miami Oolite, Anastasia Formation, Key Largo Formation, and Fort Thompson Formation (Pleistocene) and the Tamiami Formation (Pliocene). The sediments in the eastern portion of the county are appreciably more permeable than in the west.

The surficial aquifer is underlain by at least 600 feet of the Hawthorn formation (confining unit). The Floridan Aquifer System underlies the Hawthorn formation.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for processing is approximately 0.24 million gallons per day (mgd) for uses such as process water and service water. Approximately 600 mgd of cooling water would be cycled through the once-through cooling water system which is a reduction of more than 51% from the previous fossil steam unit's capability. Potable water demand is expected to average .001 mgd.

l. Water Supply Sources by Type

The modernized plant will continue to use the Intracoastal Waterway as the source of once-through cooling water. Process and potable water for the new plant will come from the existing City of Ft. Lauderdale potable water supply.

m. Water Conservation Strategies Under Consideration

No additional water resources will be required as a result of the modernization project. CC technology uses less water by design than traditional steam generation units.

n. Water Discharges and Pollution Control

The modernized plant will utilize portions of the existing once-through cooling water system for heat dissipation. The heat recovery steam generator blowdown will be reused to the maximum extent practicable or mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's once-through cooling water system prior to discharge. Stormwater runoff will be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for the new unit would be transported to the site via an existing natural gas pipeline to the site. New gas compressors to raise the gas pressure of the pipeline to the appropriate level for the new unit will be installed either at the existing site or off-site. Ultra-low sulfur light fuel oil would be received by truck, pipeline, or barge and stored in a new above-ground storage tank.

p. Air Emissions and Control Systems

The regulated air emission rates at the new plant would be approximately 90 percent lower than the previous Port Everglades Plant's emission rates, resulting in significant annual emissions reductions and air quality benefits per unit of energy produced. The use of natural gas, ultra-low sulfur light fuel oil, and combustion controls would minimize air emissions from the unit and ensure compliance with applicable emission limiting standards. Using these fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x) and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. CC facility emissions of greenhouse gas emissions (GHGs) from combustion of natural gas achieve an emission rate substantially lower than the EPA proposed new source performance standards for GHGs. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of PEEC would incorporate features that will make it among the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site.

r. Status of Applications

FPL filed a need determination with the FPSC on November 21, 2011. The FPSC's final need order was issued on April 9, 2012. The Site Certification Application (SCA) was submitted January 24, 2012 resulting in the issuance of Final Order PA 12-57 on October 9, 2012. Concurrent with the SCA filing, FPL submitted applications for a Greenhouse Gas (GHG) permit, a Prevention of Significant Deterioration (PSD) permit, and an Industrial Wastewater Facility permit revision. The revised Industrial Wastewater Facility permit was issued

December 16, 2012. The GHG permit was issued December 26, 2013 and the PSD permit was issued May 1, 2012.

Preferred Site # 2: Lauderdale Plant, Broward County

This site is located at and situated within the existing FPL Lauderdale Plant property, approximately 392 acres, within the Cities of Dania Beach and Hollywood in Broward County, Florida. The jurisdiction for the City of Hollywood is a small area south of SW 42nd Street in the eastern portion of the property. The remainder of the Plant property is located in the City of Dania Beach. The Plant property is located east of U.S. Highway 441, north of Griffin Road, west of SW 30th Avenue, and south of Interstate 595. The existing accesses to the Plant are from SW 24th Avenue and SW 42nd Street. The adjacent properties include residential properties to the south, the South Broward County Resource Recovery Facility to the west, Pond Apple Slough to the north and commercial properties to the east.

The Lauderdale Plant includes two banks of 12 simple cycle gas turbines (GTs) that began operation in the early 1970s. These GTs are first generation GTs that are used to serve peak and emergency demands in a quick-start manner. Each bank of GTs has a net capacity of 420 (Summer) megawatts (MWs), and are authorized to operate on natural gas and distillate oil. Due to new nitrogen dioxide (NO_2) environmental regulations, FPL filed in June 2013 for FPSC approval to recover costs for removing all of its existing GTs and replacing a portion of the GT capacity with new CTs. In December 2013, FPL withdrew this request pending additional environmental monitoring and analyses. Computer modeling of the emissions from the GTs projected that the GTs would exceed the new NO_2 limit. FPL believes this monitoring and analyses will confirm that the operation of its existing GTs in Broward County will not comply with the new NO_2 regulations. Therefore, for planning purposes, FPL has assumed that all of its existing Broward County GTs will be removed (a loss of 1,260 MW Summer) and that this capacity will be partially replaced by 5 new CTs that would be sited in Broward County (an increase of 1,005 MW Summer). This GT removal and CT partial replacement is assumed to occur by the end of 2018.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Lauderdale site is found at the end of this chapter.

b. Proposed Facilities Layout

A general layout of the Lauderdale generating facilities is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing Lauderdale Plant includes two combined cycle units (Units 4 and 5) and two banks of 12 simple cycle gas turbines (GT1 through GT12 and GT13 through GT24). Units 4 and 5 have net capacity of 442 (Summer) MW each. Each bank of GTs has a net capacity of 420 (Summer) MW. The northern portion of the property is comprised of a forested wetland area adjacent to the Pond Apple Slough.

The adjacent properties to the Lauderdale Site include residential properties to the south, the South Broward County Resource Recovery Facility to the west, Pond Apple Slough to the north and commercial properties to the east. The Dania Cut-off Canal is located along the southern boundary and the South New River Canal is located along the western and northern boundaries.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

FPL Lauderdale Plant property consists of approximately 392 acres, within the Cities of Dania Beach and Hollywood in Broward County, Florida. The Project area comprises approximately 20 acres in the northern portion of the existing Plant site, and includes the approximately 6-acre north gas turbine site containing 12 gas turbines as well as approximately 14 acres of surrounding forested wetlands and upland spoil piles.

2. Listed Species

No negative impacts to threatened or endangered species are anticipated as a result of the CT Project.

Based upon the field assessment conducted in 2013, review of United States Fish and Wildlife (USFWS) and Florida Fish and Wildlife Conservation Commission (FWC) literature and databases, the Florida Natural Areas Inventory (FNAI) database of documented listed species occurrences, and the lack of suitable habitat, federally listed species are not anticipated to utilize the CT Project area. The potential occurrence of listed flora and fauna within the CT Project area is limited due to the surrounding land uses (industrial, commercial, and residential areas, as well as Ft. Lauderdale-Hollywood International Airport), and lack of suitable habitat within and surrounding the CT Project area to support partial or full life-cycle requirements of federally listed species known to occur within Broward County.

3. Natural Resources of Regional Significance Status

The construction and operation of the CT Project at this location is consistent with the existing use at the site and is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands. No named wetlands, named surface waters, Outstanding Florida Waters, or Aquatic Preserves would be impacted by the proposed Project.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

In the event monitoring confirms that emissions from operation of the existing GTs would not comply with the NO_2 regulations, the design option is to remove 24 gas turbines (GTs) at the existing Lauderdale Plant, and an additional 12 simple cycle GTs at their nearby Port Everglades Plant, and replace them with five new highly efficient simple cycle combustion turbines (CTs). The CTs operate in simple cycle mode with associated stacks and produce electrical energy by direct connection to an electric generator. The CTs will operate using natural gas and ultra-low sulfur distillate (ULSD) oil as fuel.

g. Local Government Future Land Use Designations

The site is zoned General Industrial by the City of Dania Beach, a designation intended to provide for light and medium intensity industrial, research, and assembly fabrication uses. Electrical power plants are permitted within a General Industrial zoning designation as a special exception use only.

A land use map of the site and adjacent areas is also found at the end of this chapter.

h. Site Selection Criteria Process

The Lauderdale Plant site has been selected as a "Preferred" for the location of peaking unit facilities due to consideration of various factors including maximizing opportunities to utilize existing utility infrastructure, system load, transmission interconnection, and economics.

i. Water Resources

The Project will require a marginal increase in demineralized water that will be obtained from the existing Lauderdale Plant's water treatment system.

j. Geological Features of Site and Adjacent Areas

According to the Natural Resource Conservation Service (NRCS) Soil Survey of Broward County, the Project area is dominated by Okeelanta muck, with Udorthents, shaped as a minor association.

The Okeelanta series consists of very deep, very poorly drained, rapidly permeable soils in large fresh water marshes and small depressional areas. They formed in decomposed hydrophytic non-woody organic material overlying sand. Slopes range from zero to two percent. In un-drained areas the water table is at depths of less than ten inches below the surface or the soil is covered by water 6 to 12 months during most years. Areas of Okeelanta muck within the Project area support a mixed native and exotic hardwood wetland community.

k. Projected Water Quantities for Various Uses

The CT Project consists of CTs that are operated in simple cycle mode and do not require a heat dissipation system. As a result, there are no associated cooling water uses, cooling water discharges, or other heat dissipation impacts.

l. Water Supply Sources by Type

The CT Project would continue to acquire water from existing water contracts with Broward County. Therefore, the Project will have no adverse impact to groundwater. The CT Project would not use onsite groundwater or a new groundwater source for any purpose. The CT Project would have no adverse impact to surface water.

The CT Project would continue to use municipal potable water from the City of Hollywood to provide drinking water for employees. There is no projected increase in employment at the Lauderdale Plant as a result of the CT Project and no associated potable water use increase for that purpose. Therefore, there would be no impact to drinking water sources from the CT Project.

m. Water Conservation Strategies Under Consideration

No additional water resources would be required as a result of the CTs project.

n. Water Discharges and Pollution Control

There would be no surface water discharges required for the operation of the CT Project, other than storm water discharges from non-contact areas. Operation of the CT Project would not generate leachate and the stormwater management system has been designed to prevent direct discharge to surface waters. Therefore, there would be no adverse impact to water supplies due to runoff or leachate from the CT Project.

The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The fuel to be used in the CTs is natural gas and ULSD oil. Natural gas will be transported to the facility via existing pipeline. No onsite storage is provided for natural gas. ULSD oil would be trucked or piped to the facility and stored in double walled ULSD oil tanks.

p. Air Emissions and Control Systems

Air emission rates for NOx with the CT Project would be approximately 90 percent lower than the existing GT emission rates, resulting in significantly lower air quality impacts. In addition to lower air emissions, the maximum total air quality impacts for the CT Project are predicted to be well below and in compliance with the National Ambient Air Quality Standards (NAAQS). For pollutants such as NO_2, the CT Project's total air quality impacts are predicted to be significantly reduced by 40 percent or more compared to the existing GTs.

The use of clean fuels (natural gas and ULSD oil) and combustion controls would minimize air emissions of SO_2, sulfuric acid mist (SAM), particulates (PM/PM10/PM2.5), and other fuel-bound contaminants and ensure compliance with applicable emission-limiting standards. Combustion controls will minimize the formation of NOx and the formation of CO and VOCs by combustor design. Further NOx reduction will be achieved by water injection during oil firing.

q. Noise Emissions and Control Systems

It is not expected that noise from the CT Project would exceed the maximum permissible sound levels in Section 17-86 of the City of Dania Beach noise ordinance. The operation of the CTs is not expected to exceed the City of Dania Beach maximum permissible sound levels in residential areas.

The design of the CT Project includes components that mitigate noise from being emitted to the surrounding environment. The majority of the noise sources, such as the CTs, are located within enclosures that mitigate sounds emitted by equipment.

Noise expected to be caused by unit construction at the site is expected to be below current noise levels for the residents nearest the site.

r. Status of Applications

No licenses or permits have been issued for the CT Project. FPL has submitted applications to: the Florida Department of Environmental Protection (FDEP) for the Prevention of Significant Deterioration (PSD) air permit; U.S. Environmental Protection Agency (EPA) for the Greenhouse Gas air permit; and to the U. S. Army Corps of Engineers (USACE) for the 404 dredge and fill permit. These applications are currently in review with the respective agencies.

Preferred Site # 3: Hendry County, Hendry County

FPL has acquired an approximately 3,120-acre site in southeast Hendry County, off CR 833. The Hendry County site has been listed as a Preferred or Potential Site in previous FPL Site Plans as a possibility for a future PV facility and/or natural gas-fired CC generation. FPL currently views the Hendry site as one of the most likely sites to be used for future large-scale generation.

a. Geological Survey (USGS) Map

A USGS map of the site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the property owned by FPL is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The existing and future land uses on the site are zoned Planned Unit Development (PUD). The PUD is currently being challenged. The existing land uses that are adjacent to the site are predominately agricultural. The property to the south is the Seminole Big Cypress Reservation.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The natural environment adjacent to the north, east, and west of the site are used predominately for agricultural activities such as improved, unimproved, and woodland pasture. The majority of the pasture lands includes upland scrub, pine, and hardwoods. The Seminole Big Cypress Reservation lies to the south.

2. Listed Species

FPL strives to have no adverse impacts on federal- or state-listed terrestrial plants and animals. Much of southwest Florida is considered habitat for the endangered Florida

Panther. Although few or no impacts are expected in association with future construction at the site, FPL anticipates minimizing or mitigating for unavoidable wildlife or wetland impacts.

3. Natural Resources of Regional Significance Status

Future construction and operation of a solar and/or a natural gas-fired CC generating facility at this location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

Options include construction of CC and/or solar power generation technologies. Mitigation for unavoidable impacts may occur through a combination of on- and off-site mitigation.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is Utility. A land use map of the site and adjacent areas is also found at the end of this chapter.

h. Site Selection Criteria Process

The Hendry County site has been selected as "Preferred" due to consideration of various factors including system load, transmission interconnection, and economics.

i. Water Resources

Groundwater is anticipated to supply water to the Hendry County site.

j. Geological Features of Site and Adjacent Areas

The site is at an approximate elevation of 10 to 12 feet above mean sea level (msl) and is located on the Immokalee Rise and the Big Cypress Spur considered terraces created by high sea level events. The terraces are composed of fine quartz sands that lie discontinuously upon the surficial aquifer system whose sediments are the Fort Thompson (Pleistocene), Caloosahatchee Marl (Pleistocene and Pliocene), and Tamiami Formations (Pliocene). Other soil types in the area include limestone rock, calcareous muds, sands, organic materials, and mixed solids.

The surficial aquifer is underlain by the Hawthorn formation (confining unit). The Floridan Aquifer System underlies the Hawthorn formation.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for processing at a CC unit is approximately 0.24 million gallons per day (mgd) for uses such as process water and service water. Potable water demand is expected to average .001 mgd. Minimal amounts of water would be required for a PV facility. Approximately 7.5 mgd of cooling water would be used in cooling towers for one CC unit.

l. Water Supply Sources by Type

Potential water supply source is groundwater. Additional evaluations are necessary to determine the exact source. Process and potable water for the new plant will come from the existing potable water supply.

m. Water Conservation Strategies Under Consideration

CC and cooling tower technologies utilize less water by design than traditional steam generation units. PV facilities have minimal water demands. Specific water conservation strategies will be evaluated and selected during the detailed design phase of any development project.

n. Water Discharges and Pollution Control

A CC unit at the site would utilize a closed cycle cooling (towers) system for heat dissipation. The heat recovery steam generator blowdown will be reused to the maximum extent practicable or mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's cooling water flow prior to discharge. Wastewater disposal is anticipated via discharge to an Underground Injection Control well system. Stormwater runoff would be collected and routed to stormwater ponds. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for a new CC unit will be transported to the site via a new natural gas pipeline lateral to the site. New gas compressors to raise the gas pressure of the pipeline to the appropriate level for the new unit may be necessary Ultra-low sulfur light fuel oil will be received by truck or pipeline and stored in an above-ground storage tank.

p. Air Emissions and Control Systems

The use of natural gas, ultra-low sulfur light fuel oil, and combustion controls would minimize regulated air emissions from a CC unit and ensure compliance with applicable emission limiting standards. Using these clean fuels minimizes emissions of SO_2, PM, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of NO_x and the combustor design will limit the formation of CO and VOCs. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra low sulfur fuel oil as backup fuel. CC facility emissions of GHGs from combustion of natural gas achieve an emission rate substantially lower than the EPA's proposed new source performance standards for GHGs. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of a CC unit would incorporate features that would make it among the most efficient and cleanest power plants in the State of Florida. PV generation does not produce air emissions.

q. Noise Emissions and Control Systems

Noise anticipated to be caused by unit construction at the site is expected to be minimal.

r. Status of Applications

FPL has not submitted any application associated with the Hendry County site.

Preferred Site # 4: NE Okeechobee County, Okeechobee County

FPL has purchased a site of approximately 2,800 acres in Northeast Okeechobee County. The site is in an unincorporated, rural area and is predominantly used for agricultural production. FPL's transmission lines intersect the property. The Northeast Okeechobee County site has been listed as a Preferred or Potential Site in previous FPL Site Plans as a possibility for a natural gas-fired CC generation and/or future PV facility. Natural gas-fired CC generation will be made possible by the May,2017 projected commercial operating date of the Florida Southeast Connection (FSC) natural gas pipeline. FSC is within 3 miles of the NE Okeechobee County site. FPL currently views the Okeechobee site as one of the most likely sites to be used for future large-scale generation.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Northeast Okeechobee site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the property owned by FPL is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The Northeast Okeechobee County site is predominantly used for agricultural production (cattle and citrus). Adjacent land uses include primarily agriculture and conservation.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the site is comprised of lands dedicated to agricultural production.

2. Listed Species

Minimal impacts to federal- or state-listed terrestrial plants and animals are expected in association with construction at the site, due to the existing developed nature of the site and lack of suitable onsite habitat for listed species.

3. Natural Resources of Regional Significance Status

The construction and operation of a power generating facility at this location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

Options include construction of PV or CC technologies. Mitigation for unavoidable impacts may occur through a combination of on- and off-site mitigation.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is predominantly unimproved pasture. A land use map of the site and adjacent areas is also found at the end of this chapter.

h. Site Selection Criteria Process

The Northeast Okeechobee County site has been selected as a Preferred Site due to consideration of various factors including system load, transmission interconnection, the proximity of the proposed FSC natural gas pipeline, and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity.

i. Water Resources

Groundwater is anticipated to supply water to the Northeast Okeechobee County site.

j. Geological Features of Site and Adjacent Areas

The hydrostratigraphy of the Northeast Okeechobee County site is similar to that of most of South Florida. In general, the groundwater system underlying Okeechobee County consists of the Surficial Aquifer System (SAS), the Intermediate Confining Unit (ICU), and the Floridan Aquifer System (FAS). The SAS consists of approximately 100 to 250 feet of undifferentiated deposits of sand, shell, clay and silt. The ICU consists of approximately 200 feet of carbonate rocks interbedded with sandy and silty clay. The multiple layers of the FAS extend thousands of feet below the ICU.

k. Projected Water Quantities for Various Uses

Potable water demand is expected to average .001 mgd. The estimated quantity of water required for processing at a CC unit is approximately 0.24 million gallons per day (mgd) for uses such as process water and service water. Approximately 7.5 mgd of cooling water would be used in cooling towers for a CC unit. Minimal amounts of water would be required for a PV facility.

l. Water Supply Sources by Type

Potential water supply source is groundwater. Additional evaluations are necessary to determine the exact source. Process and potable water for the new plant will come from the existing a potable water supply.

m. Water Conservation Strategies Under Consideration

CC technology utilizes less water by design than traditional steam generation units. PV facilities have minimal water demands. Specific water conservation strategies will be evaluated and selected during the detailed design phase of any development project.

n. Water Discharges and Pollution Control

A CC plant is anticipated to utilize a closed cycle cooling (towers) system for heat dissipation. The heat recovery steam generator blowdown will be reused to the maximum extent practicable or mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's cooling water flow prior to discharge. Wastewater disposal is anticipated via discharge to an Underground Injection Control well system. Stormwater runoff would be collected and routed to stormwater ponds. The facility will employ Best

Management Practices (BMP) and Spill Prevention, Control, and Countermeasure (SPCC) plans to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

Natural gas for a new CC unit will be transported to the site via a new natural gas pipeline lateral. New gas compressors to raise the gas pressure of the pipeline to the appropriate level for the new unit may be necessary. Back-up fuel supplies of ultra-low sulfur light fuel oil will be received by truck or pipeline and stored in an above-ground storage tank to ensure reliability of operations.

p. Air Emissions and Control Systems

The use of natural gas, ultra-low sulfur light fuel oil, and combustion controls would minimize regulated air emissions from a CC unit and ensure compliance with applicable emission limiting standards. Using these clean fuels minimizes emissions of SO_2, PM, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of NO_x and the combustor design will limit the formation of CO and VOCs. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra-low sulfur light fuel oil as backup fuel. CC facility emissions of GHGs from combustion of natural gas achieve an emission rate substantially lower than the EPA's proposed new source performance standards for GHGs. These design alternatives are equivalent to the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of a CC unit would incorporate features that would make it among the most efficient and cleanest power plants in the State of Florida. PV generation does not produce air emissions.

q. Noise Emissions and Control Systems

Noise anticipated to be caused by unit construction at the site is expected to be minimal.

r. Status of Applications

FPL has not filed any applications associated with the Northeast Okeechobee County site.

Preferred Site # 5: Putnam Site, Putnam County

FPL is currently evaluating the existing Putnam Plant site for future natural gas-fired generation as part of a potential modernization project. This 66 acre site is located on the east side of Highway 100 opposite the former FPL Palatka Plant in East Palatka. The Putnam site has been listed as a Potential Site in previous FPL Site Plans as a possibility for future natural gas-fired CC generation.

FPL currently views the Putnam site as one of the most likely sites to be used for future large-scale generation.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Putnam site is found at the end of this chapter.

b. Proposed Facilities Layout

A map of the property owned by FPL is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The Putnam site is designated as Industrial land use. Adjacent land uses include power generation and associated facilities (the former Palatka Plant) as well as Mixed Wetland Hardwoods, Residential, and Hardwood-Coniferous Mixed.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the site is developed and has facilities necessary for power plant operations. No significant environmental features have been identified at this time.

2. Listed Species

Minimal impacts to federal- or state-listed terrestrial plants and animals are expected in association with construction at the site, due to the existing developed nature of the site and lack of suitable onsite habitat for listed species.

3. Natural Resources of Regional Significance Status

The construction and operation of a power generating facility at this location is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

Options include construction of CC technology. Mitigation for unavoidable impacts may occur through a combination of on- and off-site mitigation.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is Industrial. A land use map of the site and adjacent areas is also found at the end of this chapter.

h. Site Selection Criteria Process

The Putnam site has been selected as a Preferred Site due to consideration of various factors including system load, transmission interconnection, and economics.

i. Water Resources

The St John's River and/or regional water supply initiatives are potential water sources.

j. Geological Features of Site and Adjacent Areas

The hydrostratigraphy of the Putnam site is similar to that of most of North Florida. In general, the groundwater system underlying Putnam consists of the Surficial Aquifer System (SAS), and the Floridan Aquifer System (FAS).

k. Projected Water Quantities for Various Uses

Potable water demand is expected to average .001 million gallons per day (mgd). The estimated quantity of water required at a CC unit is approximately 0.24 mgd for uses such as process water and service water. Approximately 7.5 mgd of cooling water would be used in cooling towers for a CC unit.

l. Water Supply Sources by Type

Potential water supply source is the St. John's River. Additional evaluations are necessary to determine the exact source. Process and potable water for the new plant will come from the existing a potable water supply.

m. Water Conservation Strategies Under Consideration

CC and cooling tower technologies utilize less water by design than traditional steam generation units. Specific water conservation strategies will be evaluated and selected during the detailed design phase of the project development.

n. Water Discharges and Pollution Control

A CC plant is anticipated to utilize a closed cycle cooling (towers) system for heat dissipation. The heat recovery steam generator blowdown will be reused to the maximum extent practicable or mixed with the cooling water flow before discharge. Reverse osmosis (R/O) reject will be mixed with the plant's cooling water flow prior to discharge. Wastewater disposal is anticipated via discharge to surface and/or ground water as is the case with the existing Putnam Plant. Stormwater runoff would be collected and routed to stormwater ponds. The facility will employ Best Management Practices (BMP) and Spill Prevention, Control, and Countermeasure (SPCC) plans to prevent and control the inadvertent release of pollutants.

o. <u>Fuel Delivery, Storage, Waste Disposal, and Pollution Control</u>

Natural gas for a new CC unit will be transported to the site via a new natural gas pipeline lateral. New gas compressors to raise the gas pressure of the pipeline to the appropriate level for the new unit may be necessary. Back-up fuel supplies of ultra-low sulfur light fuel oil will be received by water-borne delivery, truck, or pipeline and stored in an above-ground storage tank to ensure reliability of operations.

p. <u>Air Emissions and Control Systems</u>

The use of natural gas, ultra-low sulfur light fuel oil, and combustion controls would minimize regulated air emissions from a CC unit and ensure compliance with applicable emission limiting standards. Using these clean fuels minimizes emissions of SO_2, PM, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of NO_x and the combustor design will limit the formation of CO and VOCs. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during operations when using ultra- low sulfur light fuel oil as backup fuel. CC facility emissions of GHGs from combustion of natural gas achieve an emission rate substantially lower than the EPA's proposed new source performance standards for GHGs. These design alternatives are equivalent to the Best Available Control Technology for air emissions and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of a CC unit would incorporate features that would make it among the most efficient and cleanest power plants in the State of Florida.

q. <u>Noise Emissions and Control Systems</u>

Noise anticipated to be caused by unit construction at the site is expected to be minimal.

r. <u>Status of Applications</u>

FPL has not submitted any applications associated with the Putnam site.

<u>Preferred Site # 6: Turkey Point Plant, Miami-Dade County</u>

The Turkey Point Plant (Turkey Point) is located on the west side of Biscayne Bay, 25 miles south of Miami. Turkey Point is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. The land surrounding Turkey Point is owned by FPL and acts as a buffer zone. Turkey Point is comprised of two natural gas/oil conventional steam units (Units 1 & 2), two nuclear units (Units 3 & 4), one combined cycle natural gas unit (Unit 5), nine small diesel generators, and the cooling canals. A capacity uprate project for the two nuclear units was successfully completed in 2013. The Everglades Mitigation Bank (EMB), an approximately 13,000 acre, FPL-maintained natural wildlife and wetlands area that has been set aside, is located to the south and west of the site.

In regard to Turkey Point Units 6 & 7, FPL is pursuing licensing for two new nuclear units at Turkey Point. Each of these two units would provide 1,100 MW of capacity. The current projections for the earliest in-service dates for the two new units remain 2022 (for Turkey Point Unit 6) and 2023 (for Turkey Point Unit 7). In addition to the two generating units, supporting buildings, facilities, and equipment will be located on the Turkey Point Units 6 & 7 site, along with a construction laydown area. Proposed associated facilities include: a nuclear administration building, a training building, a parking area, an FPL reclaimed water treatment facility and reclaimed water pipelines, radial collector wells and delivery pipelines, an equipment barge unloading area, transmission lines (and transmission system improvements elsewhere within Miami-Dade County), access roads and bridges, and potable water pipelines.

a. U.S. Geological Survey (USGS) Map

USGS maps of the Turkey Point area, with the proposed location of Turkey Point Units 6 & 7 identified, are found at the end of this chapter.

b. Proposed Facilities Layout

Maps of the general layout of Turkey Point Units 6 &7 are found at the end of this chapter.

c. Map of Site and Adjacent Areas

Land Use / Land Cover overview maps of the Turkey Point Units 6 & 7 site and adjacent areas are also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

Turkey Point Plant is currently home to five generating units and support facilities that occupy approximately 150 acres of the approximately 9,400-acre Turkey Point property. Prominent features beyond the power block area include the intake system, cooling canal system, switchyard, spent fuel storage facilities, and technical and administrative support facilities The cooling canal system occupies approximately 5,900 acres.

The two 400-megawatt (MW) (nominal) fossil fuel-fired steam electric generation units at Turkey Point have been in service since 1967 (Unit 1) and 1968 (Unit 2). These units have historically burned residual fuel oil and/or natural gas with a maximum equivalent sulfur content of one percent. Unit 2 is currently serving, not as a power generating unit, but as a synchronous condenser to provide voltage support to the southeastern end of FPL's transmission system. The two original 700-MW (nominal) nuclear units have been in service since 1972 (Unit 3) and 1973 (Unit 4) and were uprated to a total of approximately 1,632 (Summer) MW's in 2013. Turkey Point Units 3 and 4 are pressurized water reactor (PWR) units. Turkey Point Unit 5 is a net 1,148 (Summer) MW natural gas-fired combined cycle unit that began operation in 2007. The site for the new Units 6 & 7 is south of existing Units 3 and 4 and occupies approximately 300 acres within the existing cooling canal system.

Properties adjacent to Turkey Point property are almost exclusively undeveloped land. The FPL-owned EMB is adjacent to most of the western and southern boundaries of Turkey Point property. The South Florida Water Management District (SFWMD) Canal L-31E is also situated to the west of Turkey Point property. The eastern portions of Turkey Point property are adjacent to Biscayne Bay, the Biscayne National Park (BNP), and Biscayne Bay Aquatic Preserve. The southeastern portion of Turkey Point property is bounded by state-owned land located on Card Sound. The Homestead Bayfront Park, owned and operated by Miami-Dade County, is situated to the north of the Turkey Point property.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

Turkey Point is located directly on the northwest, west, and southwest shoreline of Biscayne Bay and the Biscayne National Park, 25 miles south of Miami. Biscayne National Park was first established in 1968 as a National Monument and was expanded in 1980 to approximately 173,000 acres of water, coastal lands, and 42 keys. A portion of Biscayne Bay Aquatic Preserve, a state-owned preserve, is adjacent to the eastern boundary of the Turkey Point plant property. The Biscayne Bay Aquatic Preserve is a shallow, subtropical lagoon consisting of approximately 69,000 acres of submerged State land that has been designated as an Outstanding Florida Water.

The approximately 300-acre Turkey Point Units 6 & 7 site consists of the plant area and adjacent areas designated for laydown and ancillary facilities. The site includes hypersaline mud flats, man-made active cooling canals, man-made remnant canals, previously filled areas/roadways, mangrove heads associated with historical tidal channels, dwarf mangroves, open water /discharge canal associated with the cooling canals on the western portion of the site, wet spoil berms associated with remnant canals, and upland spoil areas.

2. <u>Listed Species</u>

Threatened, endangered, and/or animal species of special concern known to occur at the site, transmission line corridors, or in the nearby Biscayne National Park, include the peregrine falcon *(Falco peregrinus)*, wood stork *(Mycteria americana)*, American crocodile *(Crocodylus acutus)*, roseate spoonbill (*Ajaja ajaja)*, little blue heron *(Egretta caerulea),* snowy egret *(Egretta thula),* American oystercatcher *(Haematopus palliates),* least tern *(Sterna antillarum)*, the white ibis *(Eudocimus albus)*, Florida manatee (Trichechus manatus latirostris), eastern indigo snake (Drymarchon couperi), snail kite (Rostrhamus sociabilis plumbeus), white-crowned pigeon (Patagioenas leucocephala), and bald eagle *(Haliaeetus leucocephalus)*. No bald eagle nests are known to exist in the vicinity of the site. The federally listed, threatened American crocodile thrives at Turkey Point, primarily in and around the southern end of the cooling canals which lie south of the Turkey Point Unit 6 & 7 area. The majority of Turkey Point is considered American crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American Crocodile and the program is credited with survival improvement and contributing to the downlisting of the American Crocodile from endangered to threatened.

Some listed flora species likely to occur at the site or vicinity include pinepink (Bletia purpurea), Florida brickell-bush (Brickellia mosieri), Florida lantana (Lantana depressa var. depressa), mullien nightshade (Solanum donianum), and lamarck's trema (Trema lamarckianum).

The construction, and operation after construction, of Turkey Point Unit 6 & 7 project is not expected to adversely affect any rare, endangered, or threatened species.

3. <u>Natural Resources of Regional Significance Status</u>

Significant features within the vicinity of the site include Biscayne National Park, the Biscayne Bay Aquatic Preserve, Miami-Dade County Homestead Bayfront Park, and Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park. Biscayne National Park contains 180,000 acres, approximately 95 percent of which is open water interspersed with more than 40 keys. The Biscayne National Park headquarters is located approximately two miles north of Turkey Point and is adjacent to the Miami-Dade County Homestead Bayfront Park, which contains a marina and day-use recreational facilities.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

For Turkey Point Units 6 & 7, the technology proposed is the Westinghouse AP1000 pressurized water reactor (PWR). This design is certified by the Nuclear Regulatory Commission (NRC) under 10 CFR 52 and incorporates the latest technology and more advanced safety features than today's nuclear plants that have already achieved record safety levels. The Westinghouse AP1000 unit consists of the reactor, steam generators, pressurizer, and steam turbine/electric generator. Condenser cooling for the Units 6 & 7 steam turbines will be accomplished using six circulating water cooling towers. The makeup water reservoir is the reinforced concrete structure beneath the circulating water system cooling towers that will contain reserve reclaimed water capacity to be used for the circulating water system. The structures for the Westinghouse AP1000 are the nuclear island (containment building, shield building, and auxiliary building), turbine building, annex building, diesel generator building, and radwaste building. The plant area will also contain the Clear Sky substation (switchyard) that will connect Units 6 & 7 to FPL's transmission system.

g. Local Government future Land Use Designations

The Turkey Point Plant site is designated by the Miami-Dade County Comprehensive Development Management Plan as an IU-3 (Industrial, Utilities, and Communications) Unlimited Manufacturing District that carries a dual designation of MPA (Mangrove Protection Area) in portions of the property. There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. Site Selection Criteria Process

For Turkey Point Units 6 & 7, FPL conducted an extensive site selection analysis leading to the selection of the Turkey Point site as the site that, on balance, provided the most favorable location for developing new nuclear generation to serve FPL's customers. The Site Selection Study employed the principles of the Electric Power Research Institute (EPRI) siting guidelines and is modeled upon applicable NRC site suitability and National Environmental Policy Act (NEPA) criteria regarding the consideration of alternative sites. The study convened a group of industry and FPL subject matter experts to develop and assign weighting factors to a broad range of site selection criteria. Twenty-three candidate sites were then ranked using the siting criteria. This review allowed the list of candidates to be reduced until the best site emerged. Key factors contributing to the selection of the Turkey Point site include the existing transmission and transportation infrastructure to support new generation, the large size and seclusion of the site while being relatively close to the load center, and the long-standing record of safe and secure operation of nuclear generation at the site since the early 1970s.

i. Water Resources

In regard to Turkey Point Units 6 & 7, the primary source of cooling water makeup will be reclaimed water from the Miami-Dade County Water and Sewer Department (MDWASD), with potable water also from MDWASD. When reclaimed water is not available in sufficient quantity and quality of water needed for cooling, makeup water will be saltwater supplied by radial collector wells that are recharged from the marine environment of Biscayne Bay. Horizontal collector wells (radial collector wells) have become widely used for the purpose of inducing infiltration from surface water bodies into hydraulically-connected aquifer systems in order to develop moderate to high capacity water supplies. Turkey Point Units 6 & 7 wastewater will be discharged via on-site deep injection wells.

j. Geological Features of Site and Adjacent Areas

Turkey Point lies upon the Floridian Plateau, a partly-submerged peninsula of the continental shelf. The peninsula is underlain by approximately 4,000 to 15,000 feet of sedimentary rocks consisting of limestone and associated formations that range in age from Paleozoic to Recent. Little is known about the basement complex of Paleozoic igneous and metamorphic rocks due to their great depth.

Generally in Miami-Dade County, the surficial aquifer (Biscayne Aquifer) consists of a wedge-shaped system of porous clastic and carbonate sedimentary materials, primarily limestone and sand deposits of the Miocene to late Quaternary age. The Biscayne Aquifer is thickest along the eastern coast and varies in thickness from 80 to 200 feet thick. The surficial aquifer is typically composed of Pamlico Sand, Miami Limestone (Oolite), the Fort Thompson and Anastasia Formations (lateral equivalents), Caloosahatchee Marl, and the Tamiami formation. The lower confining layers below the surficial aquifer range in thickness from 350 to 600 feet and are composed of the Hawthorn Group. Beneath the Hawthorn Group, the Floridan Aquifer System ranges from 2,800 to 3,400 feet thick and consists of Suwannee Limestone, Avon Park Limestone, and the Oldsmar Formations.

k. Projected Water Quantities for Various Uses

The estimated quantity of water required for the new Turkey Point Units 6 & 7 for industrial processing is approximately 936 gallons per minute (gpm) for uses such as process water and service water. Approximately 55.3 million gallons per day (mgd) of cooling water would be cycled through the cooling towers. Water quantities needed for other uses such as potable water are estimated to be approximately 50,400 gallons per day (gpd) for Units 6 & 7.

l. Water Supply Sources and Type

The water for the various water needs of Turkey Point 6 & 7 will be obtained from a reclaimed water supply, a saltwater supply, and a potable water supply. Reclaimed water will be used as makeup water to the cooling water system with saltwater from radial collector wells as a back-up water source to be used when reclaimed water is not available in sufficient quantity or quality.

Potable water will be used as makeup water for the service water system. The potable water supply will also provide water to the fire protection system, demineralized water treatment system, and other miscellaneous uses.

m. Water Conservation Strategies

Use of reclaimed water from MDWASD Turkey Point Units 6 & 7 is a beneficial and cost-effective means of increasing the use of reclaimed water. This use of reclaimed water helps Miami-Dade County meet approximately half of its wastewater reuse goals and will provide environmental benefits by reducing the volume of wastewater discharged by the County. In the absence of reuse opportunities, this treated domestic wastewater would likely continue to be discharged to the ocean or into deep injection wells.

Miami-Dade County is required to eliminate ocean outfalls and increase the amount of water that is reclaimed for environmental benefit and other beneficial uses. Turkey Point Units 6 & 7 will use reclaimed water 24 hours per day, 365 days per year when operating and when the reclaimed water is available in sufficient quantity and quality.

n. Water Discharges and Pollution Control

Turkey Point Units 6 & 7 will dissipate heat from the power generation process using cooling towers. Blowdown water or discharge from the cooling towers, along with other wastestreams, will be injected into the boulder zone of the Floridan Aquifer. Non-point source discharges are not an issue since there will be none at this facility. Storm water runoff will be released to the closed-loop cooling canal system.

Turkey Point Units 6 & 7 will employ Best Management Practices (BMP) plans and Spill Prevention, Control, and Countermeasure (SPCC) plans to prevent and control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The Turkey Point Units 6 & 7, reactors will contain enriched uranium fuel assemblies. A fuel assembly consists of 264 fuel rods, 24 guide thimbles, and 1 instrumentation tube in a 17-by-

17 square array. The fuel rods consist of enriched uranium, in the form of cylindrical pellets of sintered uranium dioxide contained in ZIRLO™ tubing.

New fuel assemblies will be transported to Turkey Point for use in Units 6 & 7 by truck from a fuel fabrication facility in accordance with U.S. Department of Transportation (DOT) and NRC regulations. Spent fuel assemblies being discharged will remain in the spent fuel pool while short half-life isotopes decay.

After a sufficient decay period, the fuel would be transferred to an on-site independent spent fuel storage installation facility or an off-site disposal facility. Packaging of the fuel for off-site shipment will comply with the applicable DOT and NRC regulations for transportation of radioactive material.

The U.S. Department of Energy (DOE) is responsible for spent fuel transportation from reactor sites to a repository under the Nuclear Waste Policy Act of 1982, as amended. FPL has executed a standard spent nuclear fuel disposal contract with DOE for fuel used in Units 6 & 7.

p. <u>Air Emissions and Control Systems</u>

Turkey Point Units 1, 2, and 5, and the emergency diesel generators associated with Units 3 and 4, are classified as a major source of air pollution. FDEP has issued a separate Title V Air Operating Permit for the fossil units at Turkey Point and for the emergency diesel generators associated with the nuclear units. There are no operating limits for the emergency generators or diesel engines. Emergency diesel generators are limited to use ultra-low sulfur diesel fuel (0.0015% sulfur). NO_x emissions are regulated under Reasonably Available Control Technology (RACT) requirements in Rule 62-296.570(4) (b) 7 F.A.C., which limit NO_x emissions to 4.75 lb/MMBtu. The use of 0.05 percent sulfur diesel fuel and good combustion practices serve to keep NO_x emissions under this limit.

Regarding Turkey Point Units 6 & 7, the units will also minimize FPL system air pollutant emissions by using nuclear fuel to generate electric power. This includes avoiding emissions of particulate matter (PM), sulfur dioxide (SO_2), nitrogen oxides (NO_x), carbon monoxide (CO), carbon dioxide (CO_2), and volatile organic compounds (VOC). The circulating water cooling towers will be equipped with high-efficiency drift or mist eliminators to minimize emissions of PM to 0.0005 percent of the circulating water; which represents 99.99-percent control of potential drift emissions based on the circulating water flow.

The diesel engines necessary to support Turkey Point Units 6 & 7 and fire pump engines will be purchased from manufacturers whose engines meet the EPA's New Source Performance Standards (NSPS) Subpart IIII emission limits.

q. <u>Noise Emissions and Control Systems</u>

Field surveys and impact assessments of noise expected to be caused by activities associated with the Turkey Point Units 6 & 7 project were conducted. Predicted noise levels associated with these projects are not expected to result in adverse noise impacts in the vicinity of the site.

r. <u>Status of Applications</u>

The Turkey Point Units 6 & 7 Site Certification Application (SCA), under the Florida Electrical Power Plant Siting Act, was filed in June 2009 and a final order is anticipated in mid-2014. The FPSC issued the final order approving the need for this additional nuclear capacity in April 2008.

A Combined License Application for Units 6 & 7 was submitted to the NRC in June 2009. There are two components to that application; one is the Environmental Assessment (EA) and the other is the Safety component. The Application is still in process.

Besides the certification and the license, additional approvals have been issued for Turkey Point Units 6 & 7 including Miami-Dade County Unusual Use approvals that were issued in 2007 and 2013 and a Land Use Consistency Determination that was issued in 2013. The Prevention of Significant Deterioration (Air permit) was issued in 2009. In addition, a permit to construct an exploratory well and a dual zone monitoring well, under the Underground Injection Control Program, was issued in 2010, and a permit to convert the exploratory well, to an injection well and to operationally test the system, was issued in 2013. Permits from the Federal Aviation Administration (FAA) for the containment structure were originally issued in 2009 and renewed in 2012.

The western transmission lines associated with Units 6 & 7 (2 500 kV New Clear Sky Substation – Levee Substation and 1 230 kV New Clear Sky Substation – Pennsuco Substation) will utilize the existing approximately 40-mile-long transmission line right-of-way acquired by FPL in the 1960s and early 1970s between the Turkey Point plant property and Levee Substation. A 7.4 mile long segment of that existing right-of-way became surrounded by the Everglades National Park in 1989 when the East Everglades Expansion Area south of Tamiami Trail (US-41) was added to the Park. The National Park Service and several other federal, state and local agencies entered into contingent agreements in 2008 to exchange

FPL's fee-owned property within the Park for an alternative right-of-way along the Park's eastern boundary (the Exchange Right-of-Way). That land exchanges was authorized by the U.S. Congress in the 2009 Omnibus Public Lands Management Act, and the National Park Service is currently engaged in a National Environmental Policy Act (NEPA) review of the proposed exchange. The Recommended Order to be considered by the Siting Board in 2014 recommends for approval FPL's West Preferred Corridor, which includes the Exchange Right-of-Way, as a back-up western transmission line corridor to another corridor. The primary western corridor recommended for approval is the West Consensus Corridor (comprising an alternate corridor proposed by the Miami-Dade Limestone Products Association and a portion of FPL's West Preferred Corridor). Both of those western transmission line corridors recommended for certification use the Exchange Right-of-Way. In the event the pending land exchange with the National Park Service and other agencies is not consummated on a timely basis, FPL will need to evaluate other potential western corridors for the western transmission lines associated with Units 6 & 7, including its existing fee-owned right-of-way in the Park, and seek necessary approvals for construction of the required transmission facilities.

IV.F.2 <u>Potential Sites for Generating Options</u>

Four (4) sites are currently identified as Potential Sites for future generation additions to meet FPL's projected capacity and energy needs.[6] These sites have been identified as Potential Sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies, including both renewable energy and non-renewable energy technologies for various sites.

Each of these Potential Sites offer a range of considerations relative to engineering and/or costs associated with the construction and operation of feasible technologies. In addition, each Potential Site has different characteristics that will require further definition and attention.

Permits are presently considered to be obtainable for each of these sites. No significant environmental constraints are currently known for any of these sites. The Potential Sites briefly discussed below are presented in alphabetical order. At this time, FPL considers each site to be equally viable.

[6] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites and other Greenfield sites. Greenfield sites that FPL currently does not own, or for which FPL has not currently secured the necessary rights to, are not specifically identified as Potential Sites in order to protect the economic interests of FPL and its customers.

Potential Site # 1: Babcock Ranch, Charlotte County

This site is located within the proposed Babcock Ranch Community on the north side of Tuckers Grade, approximately 10.5 miles north of the intersection of SR-80 and SR-31 and 1.1 miles east of SR-31. The project is bordered on the north by the Babcock Ranch Preserve owned by the State of Florida. This site is a possibility for an FPL PV facility. FPL has received all permits necessary to construct a 74 MW PV facility at this location.

a. U.S. Geological Survey (USGS) Map

A map of this site is found at the end of this chapter.

b. Land Uses

Existing land use on the site is the Babcock Ranch Overlay District, and it is zoned as the Babcock Ranch Overlay Zoning District. This land use and zoning allows for solar facilities.

c. Environmental Features

FPL anticipates mitigating for unavoidable wildlife and/or wetland impacts as needed as a result of a PV project constructed at this site.

d. Water Quantities

Minimal amounts of water, if any, would be required for a PV facility.

e. Supply Sources

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the solar panels in the absence of sufficient rainfall. Any such water may be brought to the site by truck.

Potential Site # 2: DeSoto Solar Expansion, DeSoto County

The DeSoto site is located at 4051 Northeast Karson Street which is approximately 0.3 miles east of U.S. Highway 17 and immediately north of Bobay Road in Arcadia, Florida. The site is located in Sections 26, 27, & 35, Township 36 South, and Range 25 East. FPL owns an approximate 13,000 acre parcel in DeSoto County. FPL has designated approximately 5,177 acres for development of a PV facility.

The DeSoto site is home to a 25 MW PV facility that has been operational since 2009. Up to an additional 275 MW of PV generation could be constructed in phases on the remaining undeveloped land. FPL has initiated permitting for the additional PV facilities.

a. U.S. Geological Survey (USGS) Map

A map of this site is found at the end of this chapter.

b. Land Uses

Existing land use on the site is agricultural. The future land use is Electric Generating Facility.

c. Environmental Features

There are no significant environmental features on the site.

d. Water Quantities

Minimal amounts of water would be required for a future expansion of the existing PV facility.

e. Supply Sources

Minimal water would be required for an expanded PV facility. A small amount may be needed to occasionally clean the PV panels in the absence of sufficient rainfall. Potable water will be required in the administration building and maintenance building. FPL would propose to utilize existing wells onsite to accommodate water needs.

Potential Site # 3: Manatee Plant Site, Manatee County

The existing FPL Manatee Plant 9,500-acre site is located in unincorporated north-central Manatee County. The existing power generating facilities are located in all or portions of Sections 18 and 19 of Township 33S, Range 20-E. The plant site lies approximately 5 miles east of Parrish, Florida. It is approximately 5 miles east of U.S. Highway 301 and 9.5 miles east of Interstate Highway 75 (I-75). The existing plant is approximately 2.5 miles south of the Hillsborough-Manatee County line. A portion of the north property boundary of the plant site abuts the county line. State Road 62 (SR 62) is about 0.7 mile south of the plant, with the plant entrance road going north from that highway. This site is a possible location for an FPL PV facility. FPL has received the federal and state permits required to construct approximately 50 MW of PV at this location.

a. U.S. Geological Survey (USGS) Map

A map of the site is found at the end of this chapter.

b. Land Uses

Existing land use on the site is agricultural. The property is zoned Planned Development / Public Interest (PD-PI), which will allow for electrical generation.

c. Environmental Features

FPL anticipates mitigating for unavoidable wildlife and/or wetland impacts as needed as a result of a PV project constructed at this site.

d. Water Quantities

Minimal amounts of water would be required for a PV facility.

e. Supply Sources

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the PV panels in the absence of sufficient rainfall. Panel cleaning water source may be existing potable water or water tank trucked to the site.

Potential Site # 4: Martin County, Martin County

FPL is currently evaluating potential sites in Martin County for a future PV facility. No specific locations have been selected at this time.

a. U.S. Geological Survey (USGS) Map

A USGS map of the county has been included at the end of this chapter.

b. Land Uses

This information is not available because a specific site has not been selected at this time.

c. Environmental Features

This information is not available because a specific site has not been selected at this time.

d. Water Quantities

Minimal amounts of water would be required for a PV facility.

e. Supply Sources

Minimal water would be required for a PV facility. A small amount may be needed to occasionally clean the PV panels in the absence of sufficient rainfall.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information." These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission limitations/constraints: external limitations and internal limitations. External limitations deal with FPL's ties to its neighboring systems. Internal limitations deal with the flow of electricity within the FPL system.

The external limitations are important since they affect the development of assumptions for the amount of external assistance that is available to the FPL system as well as the amount and price of economy energy purchases. Therefore, these external limitations are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In the loss of load probability (LOLP) portion of its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission limitations are addressed by identifying potential geographic locations for potential new generating units that minimize adverse impacts to the flow of electricity within FPL's system. The internal transmission limitations are also addressed by developing the direct costs for siting new units at different locations, by evaluating the cost impacts created by the new unit/unit location combination on the operation of existing units in the FPL system, and/or by evaluating the costs of transmission additions that may be needed to address regional concerns regarding an imbalance between load and generation in a given region. Both of these site- and system-related transmission costs are developed for each different unit/unit location option or groups of options. When analyzing DSM portfolios, such as in a DSM Goals docket, FPL also examines the potential of utility DSM energy efficiency programs to avoid/defer regional transmission expenditures that would otherwise be needed to import power into that region by lowering electrical load in Southeastern Florida. In addition, transfer limits for capacity and energy that can be

imported into the Southeastern Florida region (Miami-Dade and Broward Counties) of FPL's system are also developed for use in FPL's production costing analyses. (A further discussion of the Southeastern Florida region of FPL's system, and the need to maintain a regional balance between generation and transmission contributions to meet regional load, is found in Chapter III.)

FPL's annual transmission planning work determines transmission additions needed to address limitations and to maintain/enhance system reliability. FPL's planned transmission facilities to interconnect and integrate generating units in FPL's resource plans, including those transmission facilities that must be certified under the Transmission Line Siting Act, are presented in Chapter III.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

FPL typically performs economic analyses of competing resource plans using as an economic criterion FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach). In addition, for analyses in which DSM levels are not changed, FPL uses the equivalent criterion of the cumulative present value of revenue requirements for the FPL system.[7]

The load forecast that is presented in FPL's 2014 Site Plan was developed in October 2014. The only load forecast sensitivities analyzed during 2013/early 2014 were high load forecast sensitivities developed to analyze FPL's potential future natural gas needs and to analyze the quality of FPL's future reserves.

[7] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis (i.e., when only new generating options are considered), the lowest electric rate basis approach and the lowest system cumulative present value of revenue requirements basis approach yield identical results in terms of which resource options are more economic. In such cases FPL evaluates resource options on the simpler-to-calculate (but equivalent) lowest cumulative present value system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its fuel price forecasts are discussed in Chapter III of this document. FPL used three fuel cost, and three environmental compliance cost, forecasts in analyses supporting its 2013 nuclear cost recovery filing. Also, in response to a request from the FPSC Staff, FPL used three fuel cost forecasts in sensitivity case analyses for the 2014 DSM Goals docket.

A Medium fuel cost forecast is developed first. Then the Medium fuel cost forecast is adjusted upwards (for the High fuel cost forecast), or downwards (for the Low fuel cost forecast), by multiplying the annual cost values from the Medium fuel cost forecast by a factor of (1 + the historical volatility in the 12-month forward price, one year ahead) for the High fuel cost forecast, or by a factor of (1 – the historical volatility of the 12-month forward price, one year ahead) for the Low fuel cost forecast.

The resource plan presented in this Site Plan is based, in part, on those prior analyses. For that reason, this resource plan has not been further tested for different fuel cost forecasts.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

As described above in the answer to Discussion Item # 3, FPL used up to three fuel cost forecasts in its 2013/early 2014 resource planning analyses. While these forecasts did not represent a constant cost differential between oil/gas and coal, a variety of fuel cost differentials were represented in these forecasts.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, capacity output ratings, and heat rate information. Schedule 1 in Chapter I and Schedule 8 in Chapter III present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options in its resource planning work. A summary of this information for the new capacity options FPL currently projects to add over the reporting horizon for this document is presented on the Schedule 9 forms in Chapter III.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

During 2013, FPL used the following financial assumptions: i) a capital structure of 40.38% debt and 59.62% equity; (ii) a 4.79% cost of debt; (iii) a 10.5% return on equity; and (iv) an after-tax discount rate of 7.45%. In early 2014, the cost of debt and the after-tax discount rate changed slightly to 5.14% and 7.54%, respectively. The other assumptions did not change. No sensitivities of these financial assumptions were used in FPL's 2013/early 2014 resource planning work.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the objective generally being to minimize FPL's projected levelized system average electric rate (i.e., a Rate Impact Measure or RIM approach). As discussed in response to Discussion Item # 2, both the electricity rate perspective and the cumulative present value of system revenue requirement perspective yield identical results in terms of which resource options are more economic when DSM levels are unchanged between competing resource plans. Therefore, in planning work in which DSM levels were unchanged, the equivalent, but simpler-to-calculate, cumulative present value of revenue requirements perspective was utilized.

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses three system reliability criteria in its resource planning work that addresses generation, purchase, and DSM options. One criterion is a minimum 20% Summer and Winter reserve margin. Another reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). The third criterion is a minimum 10% generation-only reserve margin (GRM) criterion. These three reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability analysis work, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the Reliability Standards established by the North American Electric Reliability Council (NERC). The *NERC Reliability Standards* are available on the internet site (http://www.nerc.com/).

In addition, FPL has developed a *Facility Connection Requirements* (FCR) document as well as a *Facility Rating Methodology* document that are also available on the internet under the Interconnection Request Information, and FPL Facility Ratings Methodologies, directories respectively at https://www.oatioasis.com/FPL/index.html.

Generally, FPL limits its transmission facilities to 100% of the applicable thermal rating. The normal and contingency voltage criteria for FPL stations are provided below:

	Normal/Contingency	
Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95/0.95	1.05/1.07
230	0.95/0.95	1.06/1.07
500	0.95/0.95	1.07/1.09
Turkey Point (*)	1.01/1.01	1.06/1.06
St. Lucie (*)	1.00/1.00	1.06/1.06

(*) Voltage range criteria for FPL's Nuclear Power Plants

There may be isolated cases for which FPL may have determined that it is acceptable to deviate from the general criteria stated above. There are several factors that could influence these criteria, such as the overall number of potential customers that may be impacted, the probability of an outage actually occurring, or transmission system performance, as well as others.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The projected impacts of FPL's DSM programs on demand and energy consumption are revised periodically. Engineering models, calibrated with current field-metered data, are updated at regular intervals. Participation trends are tracked for all of FPL's DSM programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants. For its load management programs, FPL conducts periodic tests of the load control equipment to ensure that the equipment is functioning correctly. These tests, plus actual, non-test load management events, also allows FPL to gauge the MW reduction capabilities of its load management programs on an on-going basis.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

The Executive Summary and Chapter III provide a discussion of a variety of system concerns/issues that influence FPL's resource planning process. Please see those chapters for a discussion of those concerns/issues.

In addition to these system concerns/issues, there are other strategic factors FPL typically considers when choosing between resource options. These include the following: (1) technology risk; (2) environmental risk, and (3) site feasibility. The consideration of these factors may include both economic and non-economic aspects.

Technology risk is an assessment of the relative maturity of competing technologies. For example, a prototype technology, which has not achieved general commercial acceptance, has a higher risk than a technology in wide use and, therefore, assuming all else equal, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of different generating technologies and their associated environmental impacts on the FPL system, including environmental compliance costs. Technologies regarded as more acceptable from an environmental perspective for FPL's resource plan are those which minimize environmental impacts for the FPL system as a whole through highly efficient fuel use, state of the art environmental controls, generating technologies that do not utilize fossil fuels (such as nuclear and solar), etc.

Site feasibility assesses a wide range of economic, regulatory, and environmental factors related to successfully developing and operating the specified technology at the site in question. Projects that are more acceptable have sites with few barriers to successful development.

All of these factors play a part in FPL's planning and decision-making, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As shown in this 2014 Site Plan, FPL's resource plan currently reflects the following major supply-side resource additions: the on-going modernization at Port Everglades, on-going upgrading of CTs in several CCs throughout FPL's system, the projected addition of CTs at FPL's Lauderdale plant site, the implementation of the previously executed EcoGen PPA, a projected new CC unit (at a site that has not yet been selected), and the projected Turkey Point Units 6 & 7.

In regard to the above capacity additions for which a need determination has already been granted, Turkey Point Units 6 & 7, did not lend themselves to a request for proposal (RFP) approach involving bids from third parties who would build new nuclear generation capacity. In addition, nuclear capacity additions are exempted from the Commission's Bid Rule by section 403.519 (4) (c). For nuclear projects, FPL's procurement activities are conducted to ensure the best combination of quality and cost for the delivered products. In regard to the modernization project at Port Everglades, the project received a Commission waiver from the Bid Rule due to attributes specific to the Port Everglades site and to modernization projects in general (such as use of existing land, water, transmission, etc.) plus other economic benefits to FPL's customers. This waiver from the Bid Rule was granted in Order No. PSC-11-0360-PAA-EI for Port Everglades.

CT upgrades are currently taking place at several CC units throughout the FPL system. FPL was approached by the original equipment manufacturer (OEM) of the CTs regarding the possibility of upgrading these units. Following negotiations with the OEM, and economic analyses that showed that upgrading was cost-effective for FPL's customers, the decision was made to proceed with the CT upgrades. That process is underway and is scheduled to be completed in 2015.

In regard to the addition of five new CTs at FPL's Lauderdale plant site, FPL anticipates selecting the CTs through negotiations with, and/or competitive solicitation of, CT manufacturers. The EcoGen PPA, which was approved by the Commission in Order No. PSC-13-0205-CO-EQ dated 5/21/13, was the result of negotiations between EcoGen and FPL.

Identification of projected self-build options, beyond those units already approved by the FPSC and Governor and Siting Board or units, such as the 2019 CC unit presented in this Site Plan, is required of FPL in its Site Plan filings and represents FPL's current view of alternatives that appear to be FPL's best, most cost-effective self-build options at present. FPL reserves the right to refine its planning analyses and to identify and evaluate other options before making decisions regarding future capacity additions. Such refined analyses have the potential to yield a variety of self-build options, some of which might not require an RFP. If an RFP is issued for Supply options, FPL reserves the right to choose the best alternative for its customers, even if that option is not an FPL self-build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

(1) FPL has identified the need for a new 230 kV transmission line that required certification under the Transmission Line Siting Act which was issued in April 2006. The new line is to be completed in two phases connecting FPL's St. Johns Substation to FPL's Pringle Substation (shown on Table III.E.1 in Chapter III). Phase 1 was completed in May 2009 and consisted of a new line connecting Pringle to a new Pellicer Substation. Phase 2 is planned to connect St. Johns to Pellicer and is scheduled to be completed by December 2018. The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

(2) FPL has identified the need for a new 230 kV transmission line (by December 2014) that required certification under the Transmission Line Siting Act which was issued on November 2008. The new line will connect FPL's Manatee Substation to FPL's proposed Bob White Substation (also shown on Table III.E.1 in Chapter III). The construction of this line, scheduled to be completed in 2014, is necessary to serve existing and future customers in the Manatee and Sarasota areas in a reliable and effective manner.

APPENDIX B

Power Purchase Agreement Key Conditions

Attachment B

Power Purchase Agreement Key Conditions

These Power Purchase Agreement Key Conditions supplement Florida Power & Light Company's ("FPL") 2015 Request for Proposals to Meet Generation Capacity Needs Beginning in 2019 (the "RFP") and sets forth certain minimum conditions (the "Conditions") that will be incorporated in any Power Purchase Agreement (the "Contract") that would be executed by and between a Proposer and FPL. The Conditions are specified below and are in addition to any other RFP requirements that a Proposer in the RFP (the "Proposer") must satisfy. Satisfaction of the Conditions, standing alone, does not ensure a Proposer's eligibility for participation in the RFP, other RFP eligibility requirements specified in the RFP must also be satisfied. (Note: In the text below, the term "Facility" refers, as applicable, to both an individual generating unit, and a system of generating units, upon which the Proposal is based.)

I. Conditions Precedent

- The Florida Public Service Commission ("FPSC") shall have issued a final Determination of Need for the Facility (if applicable), which order is not subject to appeal.
- The FPSC shall have issued a final order approving the Contract and finding that FPL is entitled to recover all costs under the Contract from its customers, which order is not subject to appeal.
- The Federal Energy Regulatory Commission ("FERC") shall have issued a final order authorizing the Proposer to make the sales contemplated by the Contract, which order is not subject to appeal.
- Each Governmental Authority having jurisdiction over the Contract shall have issued a final order of approval, which order is no longer subject to appeal.

II. Completion Security, Performance Security

- Proposer shall provide Completion Security and Performance Security in the amount, form, and in accordance with the schedule set forth in the RFP.

III. Capacity Payment

- Capacity Payments will be on a sliding scale, based upon the Facility's annual capacity billing Factor ("ACBF").
- The Facility's ACBF will be determined by FPL and calculated based on (i) the Facility's availability measured on a rolling twelve month average, and (ii) weighted based on the Facility's Peak Period availability (60%) and Non-Peak

availability (40%). "Peak Period" means those hours (i) from 12:00 p.m. to 9:00 p.m. during the months of April through October, and (ii) from 6:00 am to 10:00 am and from 6:00 pm to 10:00 pm during the months January through March and November and December. "Non-Peak" means all other hours. Additionally, the average Peak Period availability will be weighted 70% for the months of December through February and June through September, with all other months weighted 30%.

- Within a band of 94% to 70% ACBF, for each 1% that the Facility's ACBF drops below 94%, then the Capacity Payment with respect to the Facility will be reduced by 4% (*i.e.*, for each 1% drop in ACBF the Capacity Payment is reduced by 4%).
- If the Facility's AFBC falls below the 70% band, no Capacity Payment shall be made with respect to the Facility.

IV. Step-In Rights, FPL's First Lien

- In addition to FPL's other remedies under the Contract, upon failure of the Proposer to meet any agreed upon milestone date, or upon any event of default by the Proposer (and failure by the Proposer to cure such default), FPL or its designee shall have the right, but not the obligation, to enter upon and complete the licensing, permitting, construction, start-up, testing, and commissioning, or operate and maintain the Facility as agent for the Proposer. FPL's step-in right shall continue until the earlier of (i) the Proposer demonstrating to FPL's reasonable satisfaction that reasons for Proposer's failure no longer applies; (ii) FPL elects in its sole discretion to cease exercising Step-In rights, or (iii) expiration or termination of the Contract.
- As security for Proposer's performance of its obligations, Proposer or FPL shall execute and record a Mortgage and Security Agreement to provide FPL with a fully perfected subordinated security interest and mortgage lien in any and all real and personal property, contractual rights, or other rights the necessary for the development, procurement, construction, operation, and maintenance of the Facility.

V. Exclusivity, Payment

- Proposer shall have no right to sell energy, capacity, or ancillary services (the "Products") generated by or attributable to the Facility to any entity except FPL during the term of the Contract. Payments under the Contract will represent a combined charge for the sale of all Products of any type provided by the Facility.

VI. Testing, Capacity Rating, Heat Rate

- In addition to a required capacity test to demonstrate Commercial Operation, FPL has the right, but not the obligation, to require Proposer to perform a capacity test once per each Summer Period, and once per each Winter Period, at FPL's sole discretion. Additionally, a capacity test will be required if Proposer is unable to comply with any material obligation under the Contract for a period of 30 days or more as a consequence of an event of Force Majeure, or at any time when the Proposer fails two consecutive times to satisfy the operating levels set by FPL dispatch instructions. Upon completion of a capacity test, the Available Capacity will be set at a level not less than the Minimum Capacity and not more than the lower of the Committed Capacity or the Continuous Capability demonstrated in the most recent capacity test.

- Consistent with the RFP, (i) the Proposer will guarantee the Facility's heat rate levels reflected in its proposal, (ii) the Facility will be subject to heat rate testing administered by FPL, and (iii) a heat rate adjustment payment will be due from Proposer in the event the Facility fails to achieve the guaranteed heat rate levels.

VII. Dispatch, Control, Operation, and Maintenance of the Facility

- Proposer shall at all times operate the Facility consistent with FPL's dispatch and control rights. Control shall be either by Proposer's manual control pursuant to FPL's oral or written directions, or by Automated Generation Control by FPL's system control center, as determined by FPL.

- During the term, Proposer shall employ qualified and trained personnel for managing, operating, and maintaining the Facility and shall ensure that such personnel are on-duty 24 hours per day, each day, throughout the term of the Contract.

- Proposer shall be responsible for compliance with all applicable NERC regulations and requirements.

- Proposer shall operate and maintain the Facility in accordance with good engineering and operating practices, including compliance with all environmental laws, regulations, and permits. Proposer shall operate the Facility with all automatic controls (except Automatic Generation Control) and protection equipment in service whenever the Facility is connected to or operating in parallel with FPL's system. Automatic Generation Control shall be operated by FPL's system control center as determined by FPL.

- Key replacement and maintenance components (Gas Turbine hot path components, for example) may be obtained only from the Original Equipment Manufacturer.

- On an annual basis, the Proposer shall submit preliminary desired outage schedules for the following five years and a detailed plan for the next year. FPL shall notify Proposer if the outage schedule is accepted, or cooperate reasonably with Proposer to agree upon an acceptable schedule. Under no circumstances will outages be scheduled during the Peak Months.

VIII. Regulatory Out

- Notwithstanding anything contrary in the Contract, if at any time FPL fails to obtain, or is denied, the authorization of the FPSC or any other legislative, judicial, or regulatory body which now has, or may have in the future, jurisdiction over FPL's rates and charges, to recover from its customers all of the payments required to be made under the terms of this Contract, or any amendment thereto, FPL may, at its sole discretion, adjust the payments made under the Contract to the amounts which FPL is authorized to recover from its customers. In this event, Proposer shall have the option to terminate the Contract upon ninety days' notice to FPL.

IX. Variable Interest Entity (VIE)

- From the effective date through the end of the term of the contract, Proposer shall covenant that from its perspective and due to any of its actions, FPL will not be required by any legal requirement or an accounting standard to consolidate Proposer or any of its affiliates or permitted assigns as a VIE in FPL's or any of its affiliates' financial statements. Proposer shall promptly notify FPL following any determination made by Proposer or its independent auditor that Proposer constitutes a VIE for which FPL is the primary beneficiary as a result of the Contract. At the time of execution of the Contract and annually thereafter, Proposer shall provide certification of compliance with this provision by the chief financial officer of the Proposer.

- If a Proposer fails to provide the required certification, or if at any time Proposer becomes a VIE and FPL becomes the Primary Beneficiary, such an event shall constitute an event of default under the Contract.

X. Greenhouse Gas (GHG) Emission Costs

- Whether FPL would pay the Proposer for their proposed unit's (or system's) share of "annual GHG emission costs for FPL total energy" calculated as reflected in the proposal evaluation would be a subject of PPA negotiations. However, FPL and its customers will not agree to pay the Proposer for any GHG emission costs due to GHG emission rates higher than submitted by the Proposer.

- In the event of a future change in law or regulation that would have the effect of shifting to or imposing upon FPL GHG emission costs not agreed to in the PPA, FPL would have the right to terminate the PPA if such additional costs were not found to be prudent and approved for FPL cost recovery by the FPSC.

APPENDIX C

Forms for Proposers

(This page is left intentionally blank.)

Forms for Proposers

A. Overview of the Required Ten (10) Forms

There are ten (10) forms that all Proposers must complete and return to FPL's RFP Contact Person by 4:00 p.m. EDT on the Proposal Due Date. These completed forms, requested attachments to these forms, and RFP Evaluation Fee will, collectively, represent a proposal. If a Proposer is submitting more than one proposal, a separate set of forms and the appropriate RFP Evaluation Fee must be submitted for each proposal. These ten forms are described in the remainder of this Appendix. If a Proposer is also submitting a variation of a proposal in which a different price and/or term (but no changes in any other attributes) is offered for a proposal, then Form # 1, Form # 4 (page 3 of 14), Form # 5 (pages 1 of 4 and 2 of 4, or 3 of 4, as appropriate), Form # 9, and Form # 10 must be completed and submitted (along with the Variation Fee).

The Proposer must submit five (5) bound hard copies of each proposal that contains the forms and requested information, and an electronic copy of the completed forms on a CD, along with the RFP Evaluation Fee and, if applicable, the Variation Fee.

As discussed in Section II.C.2 of the RFP document, FPL will treat as confidential all information contained in proposals which is clearly identified as Proprietary and Confidential except for the information to be submitted on Form # 1, Public Information Regarding Proposal. To clearly identify confidential information, the Proposer must (1) stamp each such page with "**Confidential Information**" <u>and</u> (2) highlight/shade the specific confidential information on the pages stamped "**Confidential Information**". (A blanket statement that an entire page, or the entire proposal, is proprietary and confidential will <u>not</u> be considered clear identification.)

Please refer to Section II.C.2 of the RFP document for a full discussion of Proposal Confidentiality.

B. Form # 1: Public Information Regarding Proposal

In order to provide general information to the public about the proposals received in response to this RFP, FPL requires that all proposal submittals include a completed Public Information Regarding Proposal form that includes a list of projects undertaken (constructed and/or operated) by the Proposer that are similar to the project now being proposed. The information contained in this form will be treated as non-confidential and non-proprietary and may be released to the public at the sole discretion of FPL.

C. Form # 2: Executive Summary of the Proposal

A one (1) page summary of the proposed project and the Proposer is sought on this form. This executive summary should highlight any major value-added features of the proposal.

D. Form # 3: Financial Information

To mitigate risk, FPL will examine the Proposer's and, if applicable, the parent/affiliate guarantor's credit/corporate profile and financial guarantees. The credit/corporate profile information includes the corporate bond rating, the commercial paper rating, and the Dunn & Bradstreet Credit Appraisal Rating.

If a Proposer will be relying on any parent/affiliate guarantees, the Proposer shall also include a description of the corporate relationship between the Proposer and the guarantor and provide a description regarding the proposed guarantor's willingness to guarantee the Proposer's obligations and the terms of the guarantee.

In addition, the proposal shall include audited financial statements for the last two years for the Proposer and, if the Proposer is relying on any parent/affiliate guarantees, for the guarantor.

E. Form # 4: Operations & Engineering Information

Form # 4 requests a variety of information that will be used in the economic evaluation and/or non-economic evaluation of proposals. The requested information is to be filled in, as applicable, on the following 9 information categories of this form:

1. Power Generation Proposal Type
2. Technology/Configuration
3. Operational Considerations: Availability, Reliability, & Operating Time Limitations
4. Fuel Information & Barometric Pressure
5. Guaranteed Firm Capacity
6. Guaranteed Heat Rates
7. Emission Rate Information[1]

[1] If the proposal is based on a system sale, the emission rate information in section 7 is to be provided for each year in the proposed term of service by attaching a separate page(s) to the Proposal.

8. Natural Gas Pipeline Connection(s)
9. Generating Units' Operating & Maintenance Experience/Performance

In response to this capacity RFP, FPL envisions that it may receive power purchase agreement (PPA) proposals based on a specific existing generating unit(s) or a new generating unit(s). In either of these cases, FPL is requesting specific information regarding the following four aspects of the proposal:

- OEM replacement parts for hot gas path (HGP) components
- Availability and reliability
- Guaranteed capacity
- Guaranteed heat rates

For proposals based on an existing generating unit, FPL is seeking the following information regarding the above mentioned four aspects of the proposal:

a) OEM: Proposers will be required to state to what extent OEM parts have been used in the "proposal" unit to-date. Proposers will be required – as part of their proposal – to explicitly state that, if selected, the proposed unit will install and continue to use OEM replacement parts for such components, and that OEM maintenance schedules will be observed. A selected Proposer will have to annually obtain from the OEM a certification that OEM replacement parts have been installed and have been maintained in accordance with the OEM schedules. If a selected Proposer fails to install, use, and properly maintain OEM parts, or fails to obtain the OEM's certification, it will be in default, and will have 120 days to cure; if not cured, FPL may terminate the PPA and/or collect damages as specified in the PPA.

b) Availability & Reliability, Peak Capacity, and Heat Rates: Proposers will be required to state to what extent the proposed unit has achieved the availability and reliability, peak capacity, and heat rate levels reflected in the proposal during the last five years, and provide evidence that demonstrates that such availability and reliability, peak capacity, and heat rate levels have been achieved (such as through the results of annual heat rate tests, capacity tests, etc.) If selected, the Proposer must guarantee in the PPA that the proposed unit will continuously achieve the availability and reliability, peak capacity, and heat rate levels reflected in the proposal. If the unit in a selected proposal fails to achieve the availability and reliability, peak capacity, and/or heat rate levels reflected in the proposal and guaranteed in the PPA, the Proposer would be subject to liquidated damages. The selected Proposer will have 120 days to cure the problem. If not cured, FPL may terminate the PPA.

c) In regard to Availability & Reliability: If the average actual or proposed (as per the calculation performed in Form # 4) EAF for a proposal based on an existing combined cycle unit is less than 80% for any year, or if the average actual (or proposed as per the calculation performed in Form # 4) EFOR for a proposal based on an existing combined cycle unit is more than 4.2% for any year, or if the average actual or proposed (as per the calculation performed in Form # 4) FOF for a proposal based on an existing combustion turbine is more than 2.6% for any year, as applicable, the proposal will be rejected.

d) In regard to Heat Rates: If a heat rate test has not been performed within the last two years, the Proposer must perform a new test and submit the results as part of the proposal.

For proposals based on a new generating unit, FPL is seeking the following information regarding the above mentioned four aspects of the proposal:

a) OEM: Proposers will be required to state to what extent OEM parts have been used in existing units operated by the Proposer. Proposers will be required – as part of their proposal – to explicitly state that, if selected, the proposed unit will use OEM replacement parts for such components, and that OEM maintenance schedules will be observed. A selected Proposer will have to annually obtain from the OEM a certification that OEM replacement parts have been installed and have been maintained in accordance with the OEM schedules. If a selected Proposer fails to install, use, and properly maintain OEM parts, or fails to obtain the OEM's certification, it will be in default, and will have 120 days to cure; if not cured, FPL may terminate the PPA and/or collect damages as specified in the PPA.

b) Availability & Reliability, Peak Capacity, and Heat Rates: Proposers will be required to state to what extent the Proposer's similar existing units have achieved the availability and reliability, peak capacity, and heat rate levels reflected in the proposal during the last five years, and provide evidence that demonstrates that such availability and reliability, peak capacity, and heat rate levels have been achieved (such as through the results of annual heat rate tests or capacity tests). If selected, a Proposer must guarantee in the PPA that the proposed unit will continuously achieve the availability and reliability, peak capacity, and heat rate levels reflected in the proposal. If the unit in a selected proposal fails to achieve the availability and reliability, peak capacity, and/or heat rate levels reflected in the proposal and guaranteed in the PPA, the Proposer would be subject to liquidated damages. The selected Proposer will have 120 days to cure the problem. If not cured, FPL may terminate the PPA.

c) In regard to Availability & Reliability: If the proposed (as per the calculation performed in Form # 4) EAF for a proposal based on a new combined cycle unit is less than 80% for any year, or if the proposed (as per the calculation performed in Form # 4) EFOR for a proposal based on a new combined cycle unit is more than 4.2% for any year, or if the proposed (as per the calculation performed in Form # 4) FOF for a proposal based on a new combustion turbine is more than 2.6% for any year, as applicable, the proposal will be rejected.

d) In regard to Heat Rates: If selected, a winning Proposer must guarantee in the PPA to provide results of annual heat rate tests for the proposed unit.

For purposes of the RFP evaluation, FPL is using the following formulae for calculating availability and reliability of proposals and the NPGU:

- Availability = (8760 - POH – FOH)/8760

- EFOR = FOH/(Service Hours + FOH) in which Service Hours are calculated based on the type of proposed unit. For example, a CC unit's Service Hours are calculated to be 8760 hours x 0.80 and a CT unit's Service Hours are calculated to be 8760 hours x 0.15.

- FOF = FOH/8760

F. Form # 5: Pricing Information for Purchased Power or System Sale Proposals

Pricing for firm capacity and energy proposals that offer power purchases or system sales must be presented on Pricing Information Form # 5. **(Note that Proposers should not include projected greenhouse gas (GHG) costs in their proposal payment values. GHG cost values, in the form of FPL's projected CO2 annual cost values in $/ton, will be addressed in FPL's evaluation based upon CO2 emission rates provided in each proposal. This evaluation approach is discussed further in Appendix D.)**

Note that FPL requires actual prices to be filled in for each year of the proposed term-of-service. Proposals indicating a first-year price followed only by a note stating that a formula is to be used for escalating that price from year-to-year are not acceptable and constitute grounds for declaring a proposal ineligible. Please refer to Section F.5 (below) for an explanation of acceptable pricing approaches a Proposer may utilize in developing the annual price values to be presented on Form # 5.

1) Guaranteed Capacity Payments

The Proposer must provide Guaranteed Capacity Payment values for the term of the proposed contract on Form # 5, page 1 of 5. Guaranteed Capacity Payment values in terms of $/kw-month must be supplied for each operational mode (*e.g.,* base operation, Incremental Level 1, or Incremental Level 2, etc.) as specified on Form # 4. Proposals must include all costs of delivering capacity and energy to the FPL System including delivery over intervening transmission systems and the cost of gas pipeline laterals, if applicable, connecting the generator to the appropriate natural gas pipeline. Proposals must utilize the Guaranteed Firm Capacity rating for Summer (temperature of 95 degrees F.), the relative humidity specified, and the appropriate barometric pressure value from the chart supplied on Form # 4 in developing the denominator for the $/kw–month values.

2) <u>Guaranteed Energy Pricing & Payments</u>

a) Fuel Prices (for Non-System sales) & Energy Charges (for System Sales)

<u>For Proposals Not Based on System Sales:</u>
On Form # 5, page 2 of 5, the Proposer may submit a Guaranteed Fuel Transportation Reservation Price ($/mmBTU per Day) for the proposed term of the contract. The Proposer must designate the pipeline (FGT, Gulfstream, Sabal Trail, Sabal Trail / Florida Southeast Connection, etc.) that will serve the facility. FPL will base the variable costs and fuel on the current (or proposed as in the case of Sabal Trail and Sabal Trail / Florida Southeast Connection) tariff rates of the pipeline selected by the Proposer. If the Proposer does not wish to provide Guaranteed Fuel Transportation Reservation Prices, and the project can be connected to Sabal Trail or Florida Southeast Connection, FPL will use its own fuel transportation cost projections (which are based on Sabal Trail and Florida Southeast Connection), plus the Proposer's lateral and meter costs (provided on Form # 5, page 5 of 5), for the purposes of proposal evaluation. If the project must be connected to FGT, Gulfstream, etc., FPL will evaluate the cost of securing additional transportation capacity on those pipelines and incorporate that cost in the evaluation of the proposal.

If the Proposer has elected to submit a Guaranteed Fuel Transportation Reservation Price, the Proposer must also submit a Guaranteed Fuel Transportation Quantity (mmBTU/day) for the proposed term of the contract. For proposals with no Guaranteed Fuel Transportation Reservation Price, FPL will base its evaluation on the value for gas quantity that must be obtained on a firm basis as identified in Form # 4, page 13 of 14, in item (8) (f).

If the Proposer has elected to submit a Guaranteed Fuel Transportation Reservation Price, the Proposer may choose to submit a Guaranteed Fuel Commodity Price ($/mmBTU per Day) for the proposed term of the contract. If the Proposer elects to not provide Guaranteed Fuel Commodity Prices, FPL will use its own fuel commodity cost projections.

FPL's projected fuel commodity costs that will be used in the RFP economic evaluations will be presented on FPL's RFP website once this RFP is issued.

For Proposals Based on System Sales:
In regard to proposals based on system sales, the Proposer must submit a Guaranteed Energy Price value for each year of the proposed term-of-service. Actual annual values must be entered on Form 5, page 3 of 5. These annual values may be based on a formula based on FPL's projected fuel commodity price forecast that is discussed above. **The formula(e) applied by the Proposer to develop the energy charge payment values must be provided and fully described on a page to be developed by the Proposer and attached to Form # 5**. This formula, combined with future actual values for each forecasted fuel cost used in the formula, will be the basis for payments that the Proposer would receive if the proposal is selected.

b) Variable O&M Payments

In addition, the Guaranteed Variable O&M Prices (in $/MWh) of the proposal for each year of the proposed term-of-service for the base operational mode and for any other operational mode must be provided for all types of proposals. This information is to be provided on Form # 4, page 2 of 5 (for non-system sale proposals) or page 3 of 5 (for system sale proposals).

In calculating these values, assume an annual capacity factor of 80% for a system sale or a baseload generating proposal and 15% for peaking capacity proposals.

3) Startup Fuel Amounts and Startup Costs

The amount of fuel needed per startup (mmBTU per startup) must be provided on Form # 5, page 4 of 5.

Startup costs (other than fuel needed for startup as discussed above) should be included, at the Proposer's choice, in either of the Proposer's Guaranteed Capacity Payments or Variable O&M Payments, and are not to be entered separately on Form # 5.

4) Costs and Information Included in the Payments

Proposals that are based on generators that need to be constructed and connected to the transmission system must include transmission interconnection costs in their Guaranteed Capacity Pricing in Form # 5, page 1 of 5.

These proposals, plus proposals that are based on existing generating units, must also include the cost of third party transmission service (if applicable) for delivery to the FPL Receipt Point, including the impact of third party transmission service losses, if appropriate, in their Guaranteed Capacity Pricing on Form # 5, page 1 of 5.

On Form # 5, page 4 of 5, each Proposer must also separately provide the specific costs of transmission interconnection that are the basis for these transmission-related costs that are included in the Guaranteed Capacity Pricing values. The Proposer must also provide information related to third party transmission service (if applicable). The Proposer must also separately provide the specific costs of the gas pipeline lateral and meter, if applicable, regarding the connection of the generator to the appropriate natural gas pipeline on Form # 5, page 5 of 5.

The information that follows pertains to these transmission interconnection costs, third party transmission service information, and the costs of the gas pipeline lateral.

a) Transmission Interconnection Costs:

- All proposals that are based on generators that need to be constructed and connected to the transmission system must demonstrate that they have a valid completed application for Generator Interconnection Service (GIS) in the FPL GIS Queue, or with the applicable third party to the extent the new generator is connected to a third party's transmission system.

- The process for requesting GIS and having a completed GIS application on the FPL system is delineated on FPL's Open Access Transmission Tariff (OATT).

- To the extent the generator(s) is connecting to the FPL system, and a transmission interconnection study has been performed and completed by FPL Transmission providing cost estimates is available, the Proposer shall provide an interconnection cost estimate based on the transmission interconnection study, along with a copy of this study. This cost estimate shall include all materials, labor, land, permitting, and overhead adders associated with upgrades of existing facilities and construction of incremental facilities required as a result of the connection, plus thermal, short circuit, and stability impacts on the transmission system. Note that if a new transmission switchyard must be constructed to connect the proposed generator(s), the cost of the transmission switchyard, including land, all necessary permits, filling, and grading must be included in the cost estimate.

To the extent a completed transmission interconnection study is not available, and the generator(s) for which the capacity is being offered is to be connected to the FPL system, the Proposer must provide a cost estimate for the interconnection along with a written explanation of the basis for this estimate. Such cost estimate shall include all materials, labor, land, permitting, and overhead adders associated with upgrades of existing facilities and construction of incremental facilities required as a result of the connection, and short circuit and stability impacts on the transmission system. Note that if a new transmission switchyard must be constructed to connect the proposed generator(s), the cost of the transmission switchyard, including land, all necessary permits, filling, and grading, must be included in this cost estimate.

Form # 5, page 4 of 5, instructs proposers to provide the "basis for this (interconnection cost) estimate". FPL reserves the right to review such cost estimates for reasonableness. To the extent that FPL determines that this cost estimate is materially incorrect or incomplete, FPL reserves the right to adjust this cost estimate as it deems necessary during the evaluation process in order to reflect an acceptable interconnection arrangement. (The actual cost of connecting the generator to the FPL system would be based on the specific GIS Queue process and the attendant studies. These actual costs will need to be addressed if the Proposer is ultimately selected.)

- To the extent the generator(s) for which the capacity is being offered is not directly connected to the FPL system, the Proposer shall provide the best available cost estimate and a written explanation of the assumptions or studies upon which this cost estimate was based on Form # 5, page 4 of 5. Such cost estimate shall include all materials, labor, land, permitting, and overhead adders associated with upgrades of existing facilities and construction of incremental facilities required as a result of the connection, plus thermal, short circuit, and stability impacts on the transmission system.

b) **Third Party Transmission Service Information:**

To the extent the generator(s) is connected to the transmission system of a third party, the Proposer shall state whether third party transmission rights have been requested and/or already procured for a portion of or all of the generation capacity being offered. To the extent a request for such long-term firm transmission right have been requested, but not yet procured, provide all available studies associated with the request.

c) **Transmission Losses:**

On Form # 5, page 5 of 5, provide the projected transmission losses (MW) associated with the third party transmission service that are accounted for in the Total Guaranteed Firm Capacity values on Form # 4.

d) **Gas Pipeline Lateral and Meter Costs:**

On Form # 5, page 5 of 5, provide the total cost of the lateral pipeline and meter station for the lateral that connects the generator to the appropriate natural gas pipeline. (This cost is to be included in the Guaranteed Capacity Payment values provided on Form # 4.)

5) **Guidance for Developing Annual Capacity Payment and Variable O&M Payment Values for Form # 5**

a) **Background**

FPL's 2015 RFP requires potential Proposers to provide annual values for Capacity Payments (that inherently may include a fixed O&M component) and Variable O&M Payments. These annual values may reflect assumed escalation over the term of a proposed contract. Proposers may either submit fixed annual values or have components of their proposal prices be subject to escalation.

In the former instance, the Proposer would be guaranteeing the actual prices for each year (*i.e.*, those are the set annual prices that would be incorporated directly into a PPA if the Proposer were selected by FPL). In so doing, a Proposer would be choosing to assume the risk/benefit of costs deviating from the annual values provided.

In the latter case, a Proposer may submit prices that are subject to future adjustment based on a formula that includes one or more of three approved indices (described below). For example, a Proposer might propose a Variable O&M charge that entails a 2019 starting value that escalates thereafter at some portion or all of the actual change in a specific index. In summary, Proposers can choose the level of risk they would assume by applying a formulaic approach or guaranteeing specific annual values.

The following describes how this can be accomplished by Proposers in response to FPL's 2015 RFP (and how FPL developed, in part, the fixed O&M and variable O&M values for its NPGU.)

b) Process

The following is provided to clarify requirements for data submitted in response to FPL's 2015 RFP as pertains to proposal pricing components that may be either fixed or subject to escalation. The approach offers Proposers the opportunity to declare the annual values that will be used to evaluate their proposal and (if the proposal is subject to escalation) the method of applying FPL-authorized indices to develop the values to be evaluated.

A Proposer must submit payment <u>values</u>, not formulae, for all years for Capacity Payment and Variable O&M Payment as described in FPL's 2015 RFP. Thus, even if a Proposer decides to base a price component on a formula/index, the Proposer must still calculate and populate the RFP Form # 5 with specific annual values (so that the proposal evaluation team can verify its understanding of the Proposer's formula) and utilize the Proposer's own values in its evaluation.

Fixed Price Procedure

If the values on Form # 5 represent fixed, guaranteed payment values, then simply completing the RFP forms as described in the RFP is sufficient. These firm, guaranteed annual payment values would be used in the evaluation and then included unchanged in the PPA should the proposal be selected.

Formulaic/Indexing Procedure for Guaranteed Capacity and Variable O&M Payments

If a Proposer chooses to develop payment values based on the use of FPL-authorized indices, and desires this method to be the basis of the evaluation and a potential PPA with FPL, the Proposer must use the following approach.

For actual payment purposes if a proposal is selected, FPL's authorized indices for the Guaranteed Capacity Payments and Variable O&M Payments are from IHS Global Insight (Global Insight), a leading economic forecasting firm. The authorized indices are presented in Table C – 1 below and consist of:

- The Global Insight escalation index for Consumer Price Index – All Urban Consumers (CPI).
- The Global Insight escalation index for Producer Price Index – All Commodities (PPI); and,
- The Global Insight escalation index for Compensation Per Hour – Non-Farm Business Sector (CPH)

Or, alternatively, a Proposer may use a formula for these two payment values based on:

- A constant escalation rate per year.

Only the indices in Table C – 1, or a formula based on a constant escalation rate, are authorized for use in submitting formulaic/indexed prices for Guaranteed Capacity Payments and Variable O&M Payments in response to this RFP.

The formula(e) applied by the Proposer to develop the payment values must be provided and fully described on an attached page to Form # 5. This formula, combined with future actual values for each index from Table C – 1 used in the formula, will be the basis for payments that the Proposer would receive if the proposal is selected. **Note that if a constant escalation rate is used in a formulaic approach, the annual values supplied in the Proposal will then be included unchanged in the PPA should the proposal be selected (*i.e.*, this formulaic approach becomes a Fixed Price Procedure as previously described).**

A Proposer may also deem that some portion of a payment is not indexed, while another segment of the payment is. For example, a Proposer's Guaranteed Capacity Payment may entail one portion that is fixed (or that escalates at a set percentage) throughout the term of the contract while another portion (*i.e.*, a fixed O&M component) may be subject to annual adjustment based on a formula that includes one or more of the FPL-authorized indices or a constant escalation rate.

In addition to a thorough description of the formula/indexing process that is proposed, a Proposer must fill out the annual values for every year of the proposed transaction

Note that if a proposal that is based on a formulaic/indexing approach using the indices presented in Table C – 1 is selected, the Proposer will not be bound by these specific annual values that will be supplied on Form # 5 – only by the formulaic/indexing process behind them. However, the annual values are essential and will be used to confirm that the proposal evaluation team understands and correctly applies the Proposer's formula/indexing process.

Formulaic/Indexing Procedure for Energy Pricing of System Sale Proposals

Similar to the discussion above, the Proposer must provide annual values for each year of the proposed term-of-service for Guaranteed Energy Pricing Payments for system sale-based proposals. These annual values may be based on formulaic approach using one or more of the FPL Fuel Commodity Cost forecast that will be posted on the RFP website once the RFP is issued. The Proposer is required to provide an explanation of this formulaic approach.

Note that if such a proposal is selected, the Proposer will not be bound by these specific annual values that will be supplied on Form # 5 – only by the formulaic/indexing process behind them. However, the annual values are essential and will be used to confirm that the proposal evaluation team understands and correctly applies the Proposer's formula/indexing process.

c) FPL's Methodology for Developing NPGU Costs

In its NPGU analyses, FPL used projections of specific annual costs for Fixed O&M (FOM), Variable O&M (VOM), and Capital Replacement. The annual values for each of these three cost categories are presented in in Table VI.B-2 in the main body of the RFP document. The FOM, VOM and capital replacement are projections from a model that utilizes as inputs constant annual escalation rates of 2.5% for FOM and VOM, and 2.0% for Capital Replacement.

Table C - 1

Price Indices
(based on Global Insight's July & August 2014 Forecasts)

Year	Consumer Price Index (CPI) (Urban All Consumers)	% Change	Producer Price Index (PPI) (All Commodities)	% Change	Compensation per Hour (Nonfarm Business Sector)	% Change
2000	1.7267	---	1.3277	---	0.7398	---
2001	1.7723	2.6%	1.3421	1.1%	0.7728	4.5%
2002	1.8032	1.7%	1.3112	-2.3%	0.7905	2.3%
2003	1.8426	2.2%	1.3812	5.3%	0.8200	3.7%
2004	1.8940	2.8%	1.4665	6.2%	0.8572	4.5%
2005	1.9585	3.4%	1.5737	7.3%	0.8884	3.6%
2006	2.0193	3.1%	1.6473	4.7%	0.9233	3.9%
2007	2.0807	3.0%	1.7268	4.8%	0.9631	4.3%
2008	2.1524	3.4%	1.8956	9.8%	0.9895	2.7%
2009	2.1499	-0.1%	1.7297	-8.8%	1.0002	1.1%
2010	2.1841	1.6%	1.8480	6.8%	1.0195	1.9%
2011	2.2548	3.2%	2.0108	8.8%	1.0421	2.2%
2012	2.2993	2.0%	2.0218	0.5%	1.0706	2.7%
2013	2.3321	1.4%	2.0341	0.6%	1.0827	1.1%
2014	2.3782	2.0%	2.0679	1.7%	1.1204	3.5%
2015	2.4124	1.4%	2.0931	1.2%	1.1576	3.3%
2016	2.4507	1.6%	2.1189	1.2%	1.1998	3.6%
2017	2.4961	1.9%	2.1639	2.1%	1.2460	3.9%
2018	2.5471	2.0%	2.2079	2.0%	1.2955	4.0%
2019	2.5976	2.0%	2.2371	1.3%	1.3469	4.0%
2020	2.6506	2.0%	2.2789	1.9%	1.3991	3.9%
2021	2.7093	2.2%	2.3238	2.0%	1.4526	3.8%
2022	2.7678	2.2%	2.3715	2.1%	1.5072	3.8%
2023	2.8271	2.1%	2.4212	2.1%	1.5643	3.8%
2024	2.8856	2.1%	2.4889	2.8%	1.6240	3.8%
2025	2.9445	2.0%	2.5460	2.3%	1.6856	3.8%
2026	3.0046	2.0%	2.5837	1.5%	1.7500	3.8%
2027	3.0647	2.0%	2.6266	1.7%	1.8160	3.8%
2028	3.1244	1.9%	2.6668	1.5%	1.8831	3.7%
2029	3.1838	1.9%	2.7074	1.5%	1.9519	3.7%
2030	3.2432	1.9%	2.7423	1.3%	2.0230	3.6%
2031	3.3056	1.9%	2.7877	1.7%	2.0954	3.6%
2032	3.3703	2.0%	2.8317	1.6%	2.1700	3.6%
2033	3.4384	2.0%	2.8755	1.5%	2.2465	3.5%
2034	3.5069	2.0%	2.9163	1.4%	2.3254	3.5%
2035	3.5770	2.0%	2.9693	1.8%	2.4083	3.6%
2036	3.6489	2.0%	3.0123	1.4%	2.4947	3.6%
2037	3.7230	2.0%	3.0586	1.5%	2.5830	3.5%
2038	3.7998	2.1%	3.1059	1.5%	2.6754	3.6%
2039	3.8787	2.1%	3.1541	1.6%	2.7711	3.6%
2040	3.9588	2.1%	3.2018	1.5%	2.8694	3.5%
2041	4.0406	2.1%	3.2495	1.5%	2.9713	3.6%
2042	4.1240	2.1%	3.2991	1.5%	3.0771	3.6%
2043	4.2092	2.1%	3.3501	1.5%	3.1870	3.6%
2044	4.2962	2.1%	3.4035	1.6%	3.3021	3.6%
2045	4.3849	2.1%	3.4578	1.6%	3.4214	3.6%
2046	4.4755	2.1%	3.5129	1.6%	3.5449	3.6%
2047	4.5679	2.1%	3.5689	1.6%	3.6729	3.6%
2048	4.6623	2.1%	3.6257	1.6%	3.8056	3.6%
2049	4.7586	2.1%	3.6835	1.6%	3.9430	3.6%

G. Form # 6: Environmental & Permitting Information

In order to fully evaluate the environmental and permitting aspects of proposals, Form # 6 requests a variety of information from 12 major categories that will be used to evaluate proposals. Each Proposer should be more inclusive rather than exclusive when responding to the information requested. If the category or information requested does not apply to the proposal, an explanation must be provided. The following are the 12 major information categories of this form:

1. Proposed Community Outreach Activities and Experience
2. Required Permits or Approvals to License or Permit the Facility
3. Description of Air Pollution Control Equipment
4. PSD/NSR Permitting
5. Water Supply Strategy
6. Water Discharge Strategy
7. Strategy to Address Land Use Issues
8. Solid/Hazardous Waste / Material Management Strategy
9. Other Infrastructure Needs or Requirements
10. Protected Species Impacts
11. Permitting Experience in Florida of Proposer and Environmental Support Contractors and Consultants
12. Proposer Compliance History (Last 5 years, i.e., 2010 – 2014)

H. Form # 7: Key Milestones

FPL's ability to maintain a certain level of system reliability for its customers will be dependent upon a selected Proposer's ability to meet the contracted Capacity Delivery Date (CDD). Because there is a possibility that the Proposer will not meet this date, FPL may have to make alternate arrangements to cover the capacity and energy shortfall. This will require FPL to monitor the Proposer's progress. Therefore, the Proposer must provide the expected completion dates for certain key project milestones on this form. When providing these key project milestones, a Proposer should carefully review the Minimum Requirements regarding Project Milestone Schedule for the specific milestones listed in Section III, part 20, of the main body of the RFP document.

A proposal that requires new power plant construction falling under the Siting Act will have to demonstrate permitting, construction, etc. schedules that allow the new plant to be in-service on or before FPL's needed in-service date of June 1, 2019.

I. Form # 8: Receipt Point(s) to FPL

Information on this form will identify the location of the receipt point(s) of each proposed capacity source(s) including a listing of the nearest substation(s).

The Proposer must also attach a readable transmission map (8.5 x 11 inches) highlighting the receipt point(s) identified above.

J. Form # 9: Proposer Exceptions

All Proposers must complete and return this Proposer Exceptions form as part of their proposal submittal. On this form, the Proposer must either indicate that they take no exceptions to any of the terms, conditions, or other facets of the RFP or must indicate that they do take exception(s). In the case in which one or more exception is taken, then for each term, condition, or other facets of the RFP to which an exception is taken, the Proposer must provide their desired revised language.

FPL will consider the number and significance of exceptions in its non-economic evaluation. FPL will not consider proposed exceptions to the RFP's Minimum Requirements for Proposals or Minimum Requirements Pursuant to Purchase Agreement.

K. Form # 10: Proposal Certification

All Proposers must complete and return this Proposal Certification form as part of their proposal submittal. An Officer of the proposing company is to certify that: (i) all information contained in the Proposer's proposal is complete and accurate and that the pricing contains all applicable costs for the proposed full term of service; (ii) that the terms, conditions, and other facets of the RFP are acceptable, except as specifically noted by the Proposer on Form # 9; (iii) the Completion Security and Performance Security described in Section IV of the main body of the RFP document are acceptable and there are no pending legal or civil actions that would affect the ability of the Proposer and/or its guarantor to maintain these security amounts; (iv) the proposal has been submitted in the legal name of the entity which would be bound by any resulting contract; (v) and that the proposal is binding, definitive, and firm and will remain open for 180 days from the Proposal Due Date.

The copies of this form that are included in the five (5) bound hard copies of the proposal must each be signed by an Officer of the proposing company.

M. Proposer's Forms

The forms that follow on the remaining pages of this Appendix are the required forms which must be completed by all Proposers for each individual proposal they wish to offer. If a variation to a proposal is offered, in which either price or term only is offered, then only forms applicable to this variation may be presented.

Other(Specify): __________

4) **Generating Facility Location (City/Co./State):** ______________________________

5) **Fuel:**
Primary: ____________________
Secondary/Backup: ____________________

6) **Proposer Classification (Select One):**
Utility (retail serving): __________
Independent Power Producer: __________
Small Power Producer: __________
Cogenerator: __________
Other (explain): __________

7) **Proposed Total Guaranteed Firm Capacity (Net MW) Delivered to FPL system** (must match information on Form # 4, item 5, Guaranteed Firm Capacity, MW):

Summer (95F): ____________ Winter (35F): __________

8) **Proposed Capacity Delivery Start Date:** __________________ (Month/Day/Year)

9) **Proposed Capacity Delivery End Date:** __________________ (Month/Day/Year)

10) **Use the space below, or a separate sheet, to list all major projects undertaken (constructed and/or operated) by the Proposer or Proposer's affiliates/parent company during the last five (5) years which are similar to the project being proposed by the Proposer in response to FPL's RFP.**

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 2: Executive Summary of the Proposal

Facility Name: ____

Please provide a one (1) page summary of the proposed project and the Proposer.

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 3: Financial Information

Facility Name: ______________________________

1) **Proposer's Legal Name:** ______________________________

2) **Physical Address:** ______________________________
____

3) **Financial/Credit Contact Person:**

Name: ______________________________
Position Title: ______________________________
Telephone: ______________________________
Fax: ______________________________
E-Mail: ______________________________

4) **Federal Tax Identification Number:** ______________________________

5) **Proposer is (Select all that apply):**

________ Corporation	________ Sole Proprietorship
________ Partnership	________ Limited Liability Company
________ Joint Venture	________ Limited Liability Partnership
	________ Other (attach description)

6) **State in which Proposer is incorporated or organized:** ______________________________

7) **Proposer Information:**

a) Dunn & Bradstreet Identification Number: ______________________________

b) Corporate Bond Ratings: ________ Sources: ____________
________ ____________

c) Commercial Paper Ratings: ________ Sources: ____________
________ ____________

d) Dunn & Bradstreet Credit Appraisal Rating: ____________

2015 Request for Proposal for 2019 Capacity

Form # 3: Financial Information

Facility Name: ____

8) **(If applicable) Parent/Affiliate Guarantor Information:**

a) Name of parent/affiliate guarantor: ______________________

b) Dunn & Bradstreet Identification Number: ______________________

c) Corporate Bond Ratings: __________ Sources: __________
__________ __________

d) Commercial Paper Ratings: __________ Sources: __________
__________ __________

e) Dunn & Bradstreet Credit Appraisal Rating: ______________

9) **If Proposer is relying on any parent/affiliate guarantees, use the space below to describe the corporate relationship between the Proposer and the guarantor. Also, provide a statement regarding the proposed guarantor's willingness to guarantee the Proposer's obligation pursuant to the form of guarantee that is to be attached to the PPA.**

____
____
____
____
____
____

10) **Provide audited financial statements for the last two years for the Proposer and, if applicable, the proposed guarantor.**

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ________________________________

1) **Power Generation Proposal Type: (Select one):**

a) Purchased Power from Existing Unit: _____
b) Purchased Power from New Unit: _____
c) System Sale: _____ Provide an attachment detailing the proposed system sale including an explanation of how the proposing utility will maintain its reserve margin/reliability requirements in regard to commitments to its Public Service Commission.

d) Qualifying Facility: _____
e) Other: _____ Provide details:

____

____

2) **Technology/Configuration:**

a) Type of Generating Unit: Select Appropriate Number from the List Below: 1
Combined Cycle = 1
Combustion Turbine = 2
All Other = 3
(Note: if "All Other = 3" is chosen, FPL will develop Proposal-specific values for calculating EFOR and EAF on Form # 4, page 3 of 14)

b) Configuration:(*e.g Combined Cycle Unit with 2 CTG/HRSG trains w/duct firing and 1 Steam Turbine, Cooling Tower with makeup water from Source A; etc):*

____

____

c) Major Equipment Technology, Supplier, Model: (*Combustion Turbine, Steam Turbine; Boiler/HRSG/Catalyst Systems):*

____

____

d) Generation/Operation Modes: (*Specify/describe basis for proposed Generation/Operation Mode(s)):*
Base Operation: ________________________________
Incremental Level 1: ________________________________
Incremental Level 2: ________________________________
Other(s): ________________________________

e) Design/Operational capabilities for extreme events (e.g. hurricanes)
Design Criteria:
i) Building Code ________________________________
ii) Wind Speed: ________________
iii) Importance Factor: ________________
Operating Criteria - specificy the maximum wind speed above which the Operator(s) will shut down the generating unit: ________________________________
Special Design/Operational Features - identify plant system(s) and capabilities
i) safe shutdown of unit with readiness for rapid restart: ________________________________
ii) blackstart unit w/o offsite power: ________________________________

____

f) General Equipment Specifications
Nominal Ratings (at rated temperature and pressure of the generator cooling medium):

____
Capability Curves (at rated temperature and pressure of the generator cooling medium): Provide as an attachment.
Nominal Power Factor: ________________________________
GSU Transformer impedances: ________________________________

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ____

2) Technology/Configuration (Continued):

g) Existing Unit(s) and OEM Replacement Parts for Hot Gas Path Components:

- For a proposal based on an existing generating unit(s), please explain to what extent OEM replacement parts for hot gas path (HGP) components have been used in the unit(s):

____

____

- If the proposal is accepted, the winning Proposer must install OEM replacement HGP parts prior to the start of delievery of capacity and energy to FPL, then continue to utilize OEM replacement HGP parts for the duration of the PPA, and agree in the PPA to annually obtain from the OEM a certification that OEM replacement have been installed and have been maintained in accordance with the OEM schedules. (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

h) Proposed New Unit(s) and OEM Replacement Parts for Hot Gas Path Components:

- For a proposal based on a new generating unit(s), please explain to what extent OEM replacement parts for hot gas path (HGP) components have been used in existing unit(s) operated by the Proposer:

____

____

- If the proposal is accepted, the winning Proposer must utilize OEM replacement HGP parts for the duration of the PPA, and agree in the PPA to annually obtain from the OEM a certification that OEM replacement have been installed and have been maintained in accordance with the OEM schedules. (Check One):

Agree ________ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

i) Historical Outage Hours for Existing Unit(s) Operated by Propser that are Similar to the New Unit being proposed:
(Provide requested data below for all such existing units)

	Base Operational Mode		Other Operational Modes	
Year	Actual Annual Planned Outage Hours	Actual Annual Forced Outage Hours	Actual Annual Planned Outage Hours	Actual Annual Forced Outage Hours
2010				
2011				
2012				
2013				
2014				

Note: Do not include Maintenance Outage Hours in these projections.

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ____________________

1	= Type of Generating Unit (from Form 4_1).
0.85	= Projected service hours for purposes of projecting EFOR and FOF.

3) Operational Considerations: Availability, Reliability, & Operating Time Limitations;

a) Outage Hours:

2049			100%	0.00%	0.00%			100%	0.00%	0.00%

Notes: 1) The specified forced outage hour values **must** reflect realistic values **over the life of the proposed capacity, not**"new & clean" unit values for all years.
2) If the EAF, EFOR, or FOF values are worse than the respective values discussed in Appendix C, Section E in any year, the bid will be rejected.

b) Operating Time Limitations:

- Provide explanation (s) for any operating time limitations attributable to facility design, permits, environmental regulations, maintenance, and/or other factors.
- Note that FPL requires that the Guaranteed Firm Capacity value quoted on Form 4_7 be capacity without run-time limitations.

Generation Operation Mode	Run-Time Limitations (e.g. hrs/yr.)	Explanation
Base Operation:		
Incremental Level 1:		
Incremental Level 2:		
Other(s):		

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ____

3) **Operational Considerations: Availability & Reliability (Continued):**

c) Existing Unit(s) and Availability & Reliability:

- For a proposal based on an existing generating unit(s), please state to what extent this generating unit(s) has achieved the outage hours reflected in the proposal during the last five years (and provide evidence that demonstrates that these outage hour levels have been achieved.)

____

- If the proposal is accepted, the winning Proposer must guarantee in the PPA that the unit will achieve outage hour levels reflected in the proposal so that the calculated EA, EFOR, and FOF levels are no worse than those projected on Form # 4, page 3 of 14. (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

d) Proposed New Unit(s) and Availability & Reliability:

- For a proposal based on a new generating unit(s), please state to what extent existing units operated by the Proposer have achieved the calculated EA, EFOR, and FOF levels projected during the past five years (and provide evidence that demonstrates that such availability and reliability levels have been achieved).

____
____

- If the proposal is accepted, the winning Proposer must guarantee in the PPA that the unit will achieve EA, EFOR, and FOF levels equal to, or better, than those calculated on Form # 4, page 3 of 14. (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the bid will be rejected.)*

4) **Fuel Information and Barometric Pressure:**

a) Primary Type of Fuel: ______________

b) Secondary/Backup Type of Fuel: ______________

c) Total operating time that unit can run at full capacity using actual on-site Secondary/Backup fuel without this stored fuel being replenished. = ______________ Hrs.
(See Minimum Requirements for Proposals, Section III)

d) Total Quantity of Secondary/Backup Fuel Stored On-Site:
Storage capacity = ______________________________
Typical On-Site Inventory for Operations = ______________________________

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ______________________________

4) Fuel Information and Barometric Pressure (continued):

c) Natural Gas Fuel -Typical Properties *(for specifying unit performance values)*

Proposer's facility shall be designed to handle the expected range of fuels from its source(s). However, all specified unit performance values provided by Proposer shall be based on the "Average Fuel Analysis" that follows below:

Wide Range Fuel Data - Natural Gas

Property Constituents (Mole%)	Average
Methane	93.56%
Ethane	3.90%
Propane	1.00%
Normal Butane	0.23%
Iso Butane	0.23%
Normal Pentane	0.05%
Iso Pentane	0.03%
Hexane	0.10%
Carbon Dioxide	0.50%
Nitrogen	0.40%
TOTAL (MOLE %)	100%
Specific Gravity	0.601
Wobbe Index	1,376.7
Btu/SCF (HHV)	1,067
Btu/SCF (LHV)	962
HHV/LHV Ratio	1.109

Notes:
1 The constituent mole % values are normalized from the AVERAGE.
2 All constituent heating values are from the 1981 GPSA Engineering Data Book.
3 FPL does not warrant or guarantee that this fuel information is the actual that will be received during operation.

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ____________________

4) Fuel Information and Barometric Pressure (continued):

d) Barometric Pressure Conditions (for specifying performance values):

The generating unit performance values specified hereinafter shall be based on barometric pressure conditions as follows:

Ambient Barometric Pressure Chart

Centerline of CTG inlet bell mouth elevation (ft.)	Barometric Pressure (PSIA)
Sea Level	14.696
25	14.687
50	14.674
75	14.661
100	14.648
150	14.622
200	14.596
250	14.5704
300	14.5445

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ______________________________

5) **Guaranteed Firm Capacity** **(Net MW @ GSU Transformer High Side unless otherwise noted *):**

a) On Primary Fuel

Ambient Conditions	Generation/Operation Mode: Base Operation **	Incremental Level 1 *,***	Incremental Level 2 *,***	Other(s) (Specify) *,***	Total Guaranteed Firm Capacity
95F,50%RH					
35F,60%RH					
95F,50%RH ***					
35F,60%RH ***					

b) On Secondary Fuel

Ambient Conditions	Generation/Operation Mode: Base Operation **	Incremental Level 1 *,***	Incremental Level 2 *,***	Other(s) (Specify) *,***	Total Guaranteed Firm Capacity
95F,50%RH					
35F,60%RH					
95F,50%RH ***					
35F,60%RH ***					

* As delivered to FPL's system adjusted for any 3rd Party transmission system losses (if applicable).

** Guaranteed firm capacity must be capacity without run-time limitations

*** Generation/Operation Mode: "Incremental Level 1" values shall be specified as incremental to "Base Operation" values; "Incremental Level 2" values shall be specified as incremental to "Incremental Level 1 values; and so forth. (Example: Base Operation may be combined cycle w/o HRSG duct burners in operation. "Incremental 1" may be the incremental performance from use of HRSG duct burners.)

Note: The guaranteed capcity values shown above **must reflect "average" capacity values over the proposed term-of-service to FPL, not** "new & clean" unit values.

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ____

5) **Guaranteed Firm Capacity (Continued):**

c) Existing Unit(s) and Guaranteed Firm Capacity:

- For a proposal based on an existing generating unit(s), please state to what extent this generating unit(s) has achieved the peak capacity levels reflected in the proposal during the last five years (and provide evidence that demonstrates that such peak capacity levels have been achieved.)

____

____

- If the proposal is accepted, the winning Bidder must guarantee in the PPA that the unit will continuously achieve the peak capacity levels reflected in the bid and provide results on annual tests of capacity. (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the bid will be rejected.)*

d) Proposed New Unit(s) and Guaranteed Firm Capacity:

- For a proposal based on a new generating unit(s), please explain to what extent existing units operated by the Proposer have achieved the peak capacity levels reflected in the proposal during the past five years (and provide evidence that demonstrates that such peak capacity levels have been achieved).

____

____

- If the proposal is accepted, the winning Proposer must guarantee in the PPA that the unit will continuously achieve the peak capacity levels reflected in the proposal and provide results on annual tests of capacity. (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

Form # 4: Operations & Engineering Information

Facility Name: ____

6) Guaranteed Heat Rates (Continued):

c) Existing Unit(s) and Guaranteed Heat Rates:

- For a proposal based on an existing generating unit(s), please state to what extent this generating unit(s) has achieved the heat rate levels reflected in the proposal during the last five years (and provide evidence that demonstrates that such heat rate levels have been achieved.)

____

____

- In regard to this evidence of actual heat rates, if a heat rate test acceptable to FPL has not been performed within the last two years, the Proposer must perform a new test and submit the results as part of the proposal. (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

- If the proposal is accepted, the winning Proposer must guarantee in the PPA that the unit will achieve the heat rate levels reflected in the proposal and provide results of annual heat rate tests (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

d) Proposed New Unit(s) and Guaranteed Heat Rates:

- For a proposal based on a new generating unit(s), please explain to what extent similar existing units operated by the Proposer have achieved the heat rate levels reflected in the proposal during the past five years (and provide evidence that demonstrates that such peak capacity levels have been achieved).

____

- In regard to this evidence of actual heat rates, if a heat rate test acceptable to FPL has not been performed for such existing units within the last two years, the Proposer must perform a new test(s) and submit the results as part of the proposal. (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

- If the proposal is accepted, the winning Proposer must guarantee in the PPA that the unit will achieve the heat rate levels reflected in the proposal and provide results of annual heat rate tests (Check One):

Agree ______ Disagree ______ *(If marked "Disagree, the proposal will be rejected.)*

Florida Power & Light Company's

2015 Request for Proposal for 2019 Capacity

Form # 4: Operations & Engineering Information

Facility Name: ____

8) **Natural Gas Pipeline Connection(s):**

a) Identify the projected source of natural gas supply (FGT, Gulfstream, Sabal Trail, or Sabal Trail / Florida Southeast Connection, etc.)

____

b) Designate the power generating facility, proposed gas pipeline delivery point, and any proposed lateral line facilities on a hard copy submittal of marked-up U.S. Geological Survey Map(s) indicating the Section(s), Township(s) and Range(s). Include one hard copy of this USGS map(s) in each of the five bound hard copies of these completed forms.

c) Provide a written description of these proposed lateral line and metering facilities to connect the interstate or intrastate gas pipeline to the generating facility, including the size of the pipe and the distance (in miles) of the generating facility from the appropriate natural gas interstate or intrastate mainline (name the mainline) that will supply the facility's gas and a detailed description of the metering facilities.

____

____

____

____

d) Provide the minimum acceptable natural gas delivery pressure at each of the following locations: (i) at the interconnection with the interstate gas pipeline, (ii) at the end of the proposed lateral line, and (iii) at the generating facility inlet.

e) Provide the Maximum Daily Natural Gas Consumption Requirement at Generating Facility:
____________________ (mmBTU/day)

f) Provide the portion of the Maximum Daily Natural Gas Consumption Requirement identified in e) above that must be obtained on a firm basis: _________ (mmBTU/day)

g) Provide the Maximum Hourly Natural Gas Consumption Requirement at Generating Facility:
____________________ (mmBTU/hour)

h) Provide the portion of the Maximum Hourly Natural Gas Consumption Requirement identified in g) above that must be obtained on a firm basis: _________ (mmBTU/hour)

* Guaranteed capacity pricing values must include all proposed payments for at least the following:
- generation capital, fuel delivery capital including lateral from the appropriate natural gas pipeline, and infrastructure capital;
- fixed O&M and capital replacement;
- transmission interconnection and 3rd party transmission service (as applicable) over another utility system(s). (See pages 3 of 4 and 4 of 4 of this form.)

* In regard to the "Pipeline" entry, please fill in the blank with one of the following: "FGT", "Gulfstream", "Sabal Trail", or "Sabal Trail / Florida Southeast Connection (FSC)".

** If $/mmBTU per Day values are not entered for each year, FPL will use its own fuel transportation forecast, plus any incremental lateral costs, for evaluation purposes for any project capable of connecting to Sabal Trail or FSC. For projects which must be connected to FGT or Gulfstream, FPL will have to evaluate the cost of acquiring additional capacity on the applicable pipeline. If $/mmBTU per Day values are entered, FPL will use those values for evaluation purposes and will use the applicable pipeline's tariff to determine the appropriate variable costs and fuel per mmBTU per Day.

*** A Guaranteed Fuel Transportation Quantity must be included for proposals with a Guaranteed Fuel Transportation Reservation Price.

**** If left blank, FPL will use its own fuel price forecast for purposes of proposal evaluation.

***** **Please refer to instructions in Section F of this Appendix.**

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 5: Pricing Information for Purchased Power or System Sale Proposals

Facility Name: ____

3) **Startup Fuel Amount Required:**

______________________ **(mmBTU per startup)**

4) **Costs and Information Included in the Payments:**

a) (For proposals that are based partially or totally on generators that need to be constructed and connected to the transmission system) Attach a copy of the completed and submitted application for Generator Interconnection Service (GIS) in the FPL GIS Queue, or which the applicable third party if the new generator is to be connected to a third party's transmission system.

b) Transmission Interconnection Costs:

Total transmission interconnection cost included in the Guaranteed Capacity Payment values provided on page 1 of 4 of this form = ______________________ (millions, 2019$)

Basis for this cost estimate is : ____

____

____

____

c) Third Party Transmission Service Information:

State whether third party transmission service rights have been requested and/or already procured for a portion of or all of the generation capacity being offered. To the extent a request for such long-term firm transmission rights have been requested, but not yet procured, provide all available studies associated with such requests.

Form # 9: Proposer Exceptions *

Facility Name: ____

*** Note: FPL will not consider proposed exceptions to the RFP's Minimum Requirements for Proposals or to the Minimum Requirements Pursuant to Puchase Agreement.**

1) With regard to this proposal, the Proposer takes no exception to terms, conditions, or other facets of the RFP (Check One): _________ Agrees _________ Disagrees

2) If the answer to item (1) above is "Disagrees", then for each term, condition, or other facet of the RFP which the Proposer takes exception to, use the space below to:

   a) identify the language (citing page and paragraph) in the RFP for which an exception is made; and,

   b) write out the Proposer's desired revised language.

Florida Power & Light Company's
2015 Request for Proposal for 2019 Capacity

Form # 10: Proposal Certification

Facility Name: ____

The undersigned certifies that: (i) all of the information submitted in its proposal to FPL is complete and accurate, and that the pricing includes all of the following applicable costs for the proposal for the proposed full term of service including, but not limited to, the following costs:

- generator construction;
- generator operation and maintenance;
- transmission interconnection and 3rd party transmission service;
- gas pipeline interconnection including lateral pipeline (or other fuel delivery capital and O&M costs); and
- cost of fuel (as applicable);

(ii) the terms, conditions, and other facets of the RFP are acceptable, except as specifically noted on Form # 9; (iii) the Completion Security and Performance Security described in Section IV of the RFP document are acceptable and there are no pending legal or civil actions that would affect the ability of the Proposer and/or it guarantor to maintain these security amounts; (iv) the proposal has been submitted in the legal name of the entity which would be bound by any resulting contract; and (v) the proposal is binding, definitive, and firm and will remain open for 180 days from the Proposal Due Date.

APPENDIX D

D.1 Evaluation Methodology – Overall Process

D.2 Transmission Integration & Losses

D.3 Net Equity Adjustment

(This page is left intentionally blank.)

D.1. Evaluation Methodology - Overall Process

A. Overview

The objective of the evaluation methodology is to determine the best generation capacity option(s) that meet the RFP eligibility requirements and FPL's RFP capacity need requirements that start in June 2019. The determination will be made after analyses of eligible proposals received in response to this RFP and FPL's next planned generating unit (NPGU) that is presented in the main body of this RFP.

An individual proposal may meet the 2019 need requirement by itself (as FPL's NPGU will do). Individual proposals that only partially satisfy the 2019 need requirement may be paired with other proposals in a portfolio of proposals that together meet the 2019 need requirement. Once portfolios have been developed that each meet FPL's 2019 need requirement, the next step is to develop multi-year resource plans. Each resource plan will incorporate: an individual proposal that fully meets FPL's 2019 resource need, FPL's NPGU that also fully meets FPL's 2019 resource need, or one of the portfolios of smaller proposals. Filler units will then be added in each resource plan to meet FPL's projected annual resource needs after 2019.

These resource plans will then be evaluated using a multi-year analysis approach that allows examination of both short-term and long-term impacts to FPL's system from the generation options. These analyses will utilize both economic and non-economic perspectives.

The economic analyses will provide a total system perspective including economic impacts related to: new generation costs, system fuel costs, transmission costs, environmental compliance costs, and FPL's cost of capital. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's levelized system average rate (*i.e.*, a Rate Impact Measure or RIM methodology). However, in cases such as a generation-only RFP evaluation in which FPL's demand side management (DSM) plans are unchanged, comparisons of competing resource plans' impacts on a levelized system average electric rate basis and on a cumulative present value system revenue requirements (CPVRR) basis will yield identical rankings of the options being evaluation. For this reason, and because it is a simpler process to perform CPVRR-based analyses than it is to perform levelized system average electric rate analyses, the economic analyses for this RFP competing resource plans evaluated in the RFP analyses will be evaluated on a CPVRR basis.

The economic analyses of proposals received in response to this capacity RFP will use a similar process to that used in analyses that led to the identification of FPL's NPGU. In its economic evaluation, FPL plans to use the UPLAN production costing model for detailed production costing work. If a large number of eligible proposals are received in response to this RFP, FPL may also use the EGEAS optimization model to perform rankings of the resource plans. The highest ranking (*i.e.*, lowest CPVRR cost) resource plans would then be evaluated using the UPLAN production costing model and FPL's Fixed Cost Spreadsheet. The Fixed Cost Spreadsheet is used to develop the fixed costs associated with each of the resource plans. These fixed costs include costs (as applicable) for: capital for new generation, fixed O&M, capital replacement, firm gas transportation, capacity payments, etc. If the number of eligible proposals received is relatively small, FPL may elect to not utilize the EGEAS model. In addition, the analyses will also utilize various spreadsheets that are discussed later in this Appendix.

All economic analyses steps will use consistent assumptions regarding fuel costs, environmental compliance costs, load growth, and generation expansion plan addition options. A designated FPL Fossil Fuel Price Forecast and the FPL Environmental Compliance Cost Forecast will be utilized in these economic analyses. (The FPL Fossil Fuel Price Forecast and the FPL Environmental Compliance Cost Forecast will be posted on the RFP website once the RFP document is issued.) In addition, load growth will be modeled using FPL's current Load Forecast and FPL's approved DSM Goals. The resulting projected firm peak load growth will require additional generation beginning in 2019, and in years beyond 2019, to maintain FPL's required reserve margin levels.

Some of the forecasts and assumptions that will be utilized in the economic analyses are different from those presented in, and utilized in the development of FPL's 2014 Ten Year Site Plan (Site Plan). Appendix E presents a list of some of the key forecasts that have changed from those used in developing the resource plan that was previously presented in the 2014 Site Plan. (FPL will file its 2015 Site Plan on April 1, 2015, *i.e.*, after the release of this RFP.) Largely as a result of these updated forecasts, FPL's current resource plan is different from that presented in the 2014 Site Plan. Appendix E also discusses key changes in FPL's resource plan through the year 2019.

Non-economic analyses will be performed to evaluate certain risks for each portfolio. These analyses will include, but not necessarily be limited to, examining the following: 1) risks associated with an eligible proposal, 2) projected FPL system emissions for each portfolio, and 3) projected FPL system fuel mix for each portfolio. The results of the non-economic analyses will then be combined with the results of the economic analyses in order to determine the best overall portfolio with which to serve FPL's customers.

The economic analysis will be coordinated and largely conducted by FPL's Resource Assessment & Planning Department. An external consultant, Sedway Consulting (Sedway), will serve as an Independent Evaluator and conduct parallel economic evaluations using a different model(s). Both FPL and Sedway will evaluate FPL's NPGU and eligible proposals received in response to the RFP. Other external consultants may be used in analyzing impacts or costs regarding transmission integration, transmission losses, and/or natural gas delivery aspects of the evaluation depending upon the number and/or complexity of the proposals received.

The non-economic analysis will be conducted by several FPL departments which may also utilize other independent consultants in their assessments. The coordination of the non-economic analysis work, and the integration of the results of the economic and non-economic analyses, will be performed by FPL's Resource Assessment & Planning Department.

The evaluation of eligible proposals, the NPGU, and the resulting resource plans will be conducted using an eight (8) step process that is summarized below.

Step 1: Initial Screening for Eligibility

This initial step determines whether proposals satisfy the Minimum Requirements for Proposals and the Minimum Requirements Pursuant to Purchase Agreement (Sections III and IV, respectively, of the main body of the RFP). Proposals that do not satisfy these Minimum Requirements will be deemed ineligible and will be returned to the Proposer, along with 50% of the RFP Evaluation Fee, and will not be evaluated further.

Step 2: Economic Evaluation of Individual Proposals (if applicable)

In order to assist in the analysis of a potentially large number of eligible proposals that might be received in response to this RFP, an economic ranking of individual eligible proposals may be made based on their individual impact to the FPL system. The results of such an analysis would be used to rank proposals based on their individual economic merit. If there are significant differences in the projected economic impacts to the FPL system among the proposals, these results may be used to reduce the number of proposals that are carried forward to the next steps of the economic evaluation. Proposals that are not evaluated beyond this step will have been shown to be non-competitive by comparison of their results to the results of other proposals that do proceed in the evaluation.

The Step 2 analyses, if applicable, will likely be performed utilizing the EGEAS optimization model. These analyses of individual proposals will address FPL system cost impacts such as capital, capacity payments, fixed and variable O&M, capital replacement, firm gas transportation, system fuel, system environmental compliance costs, and other impacts effects from a resource plan perspective, including the ability of a proposal to help meet post-2019 resource needs.

If there are a relatively small number of eligible proposals, FPL may choose to forego this step of evaluating individual proposals and proceed to the creation and evaluation of portfolios and/or resource plans.

Step 3: Creation and Initial Evaluation of Portfolios and/or Resource Plans

Eligible proposals that remain after Step 1 (and, if applicable, Step 2) will then be incorporated into resource plans for further analyses. If a proposal is large enough by itself to meet FPL's 2019 resource needs, this proposal will be the only generation addition assumed to be added in 2019. Smaller proposals that cannot, by themselves, fully meet FPL's 2019 resource needs, would be combined, if possible, into a portfolio of proposals that in combination meets the 2019 resource need. Then large proposals and portfolios of smaller proposals will be incorporated into separate multi-year resource plans that address 30 years beyond 2019. In addition, a separate resource plan will assume the NPGU alone is added in 2019.

Each resource plan will then be evaluated for all system cost impacts, such as capital and other fixed costs, fuel and other variable costs, transmission interconnection and integration costs, system losses, and system environmental costs. These analyses will be performed utilizing FPL's Fixed Cost Spreadsheet and the UPLAN production costing model. FPL will utilize its Fixed Cost Spreadsheet to develop the fixed costs associated with each of the resource plans. These fixed costs include costs for: capital, fixed O&M, capital replacement, firm gas transportation, and capacity payments.

The UPLAN production costing model will be used to develop the variable annual costs of system operation for the resource plans. (The UPLAN model will be used by FPL in FPL's fuel cost recovery filings beginning in 2015, as well as in other production cost applications, and was used in the identification of FPL's NPGU for this capacity RFP.) This detailed, hourly production costing model will develop the projected annual fuel and variable O&M costs for each of the resource plans. This production costing model will also account for limitations on the amount of power that can be imported into the Southeastern Florida area and the corresponding impacts on the operation of FPL generating units located in Southeastern Florida. The UPLAN model, and potentially additional spreadsheet analysis, will be used to develop the environmental compliance costs of each portfolio.

Step 4: Development of Additional System Costs for Resource Plans

At the conclusion of Step 3, competitive resource plans will then undergo additional economic analyses as well as a non-economic evaluation. In Step 4, four additional system cost areas will be specifically developed for each resource plan, as applicable. These system costs are: (a) transmission-related costs, (b) fuel system-related costs, (c) greenhouse gas (GHG) emission-related costs, and (d) the net impact on FPL's cost of capital. In regard to the first two of these cost items, the specific siting of the proposed generation will be a key factor.

4a. Transmission-Related Costs

The following transmission-related costs will be calculated:
- transmission integration costs;
- costs related to system capacity (MW) losses at FPL's system peak hour and costs related to system annual energy (MWh) losses; and,
- impacts of the resource plans on maintaining a balance between load and generation in the Southeastern Florida region (*i.e.*, Miami-Dade and Broward counties).

The transmission integration facilities that are needed for each resource plan will be determined first. Next, costs for these integration facilities will be calculated. A transmission system analysis will then be conducted of each resource plan assuming that these integration facilities are in place. This analysis will serve as the basis to estimate the transmission system capacity losses at the system peak hour and annual energy losses associated with the resource plan. Costs will be assigned to these projected losses. In addition, the location of proposed generation capacity in each resource plan will be evaluated in regard to how it is projected to affect FPL's ability to maintain a balance between load and generation in the Southeastern Florida region consisting of Miami-Dade and Broward counties. Proposed generation capacity that is located in that region may be credited with the benefit of avoiding/deferring the costs of transmission projects projected to maintain this balance. (In addition, the production costing analyses will automatically account for the impact of the location of proposed generation capacity on the dispatch of FPL's generation system.)

Other transmission-related costs, including transmission interconnection costs and the costs of 3rd party transmission services (if applicable), are to be included in the price provided for each individual proposal. These items are discussed in more detail in Section D.2. below. (The cost of the NPGU presented in the main body of this RFP includes both transmission interconnection and integration costs.)

4b. Fuel System-Related Costs

As applicable, a more detailed analysis of the fuel system-related costs for each resource plan will be developed. Such an analysis will utilize the specific location of the generator(s) contained in the portfolio and the designated natural gas pipeline(s) to provide a more definitive estimate of the firm fuel transportation costs required to provide the necessary firm transportation at the appropriate pressures and volume to the portfolio consistent with FPL's normal fuel system management practices.

In addition, FPL will be evaluating the portfolio and resource plan to identify if "upstream" capital costs associated with additional natural gas pipeline and/or compression facilities will be needed to supply the proper volume and pressure of natural gas to the units in the portfolio.

4c. GHG Emission-Related Costs

For evaluation purposes, carbon dioxide (CO2) emission will serve to represent GHG emissions. All proposals will be required to provide the CO2 emission rates (lbs/MMBtu) of each proposed individual unit or, in the case of a system sale, the projected annual system emission rates (tons/MWh), for CO2 emissions. FPL will use these emission rates to calculate FPL's total projected annual system CO2 system emissions (tons) for each resource plan that includes one or more proposals. This approach will also apply to the resource plan with the NPGU. FPL and Sedway will then apply FPL's current projection of annual CO2 emission costs ($/ton) to these annual CO2 emissions so that the total annual emission costs that could be attributable to all energy generated to meet FPL customers' needs ("annual CO2 emission costs for FPL total energy") are calculated for each resource plan. FPL's projection of annual CO2 emission costs ($/ton) will be posted on the RFP website once the RFP is issued. From these annual CO2 emission costs, FPL will calculate a CPVRR CO2 emission cost value for the length of the analysis period for each resource plan. This CPVRR CO2 emission cost value will then be added to the projected fixed and variable CPVRR cost for the resource plan in the same way that CPVRR costs for transmission integration, losses, and net equity adjustment (see below) will be added. Together, the sum of all of these CPVRR costs will represent the total CPVRR cost for the resource plan.

4d. Net Equity Adjustment

FPL will also estimate the impact to FPL's cost of capital associated with entering into a new purchased power agreement(s). The costs of the resulting impact on FPL's capital structure are referred to as an equity adjustment. It is also recognized that a power purchase agreement also has the potential to mitigate completion and/or performance risks that would otherwise be borne by FPL if FPL were to construct a new generating unit. FPL assigns a cost savings to these "mitigating factors" and subtracts these values from the equity adjustment amount to derive a net equity adjustment. An explanation of the net equity adjustment evaluation, including an example calculation, is presented in Section D.3. below.

Step 5: Detailed Evaluation of Total System Costs

In Step 5, the CPVRR costs for each resource plan calculated in Step 3 are added to the additional system costs developed in Step 4 to produce a total system CPVRR cost for each resource plan. This total cost value represents the result of the full economic evaluation for each resource plan. The results for each resource plan, presented in CPVRR form, will be compared to the results for all other resource plans.

Step 6: Non-Economic Evaluation of Portfolios

A non-economic evaluation will be conducted on parameters that, by their nature, are unable to be integrated into the economic evaluation. These parameters describe factors that represent elements of risk that FPL must evaluate in all generation addition scenarios as well as other non-economic factors such as projections of system emissions and system fuel mix. Detailed information requirements designed to assist FPL in certain aspects of the non-economic evaluation are outlined in the submittal forms in this RFP that are presented and discussed in Appendix C. These submittal forms will be used to evaluate specific risk-related parameters that can be summarized as falling into one or more of the following three areas:

6a. Environmental Area

- Items related to the Proposer's ability to successfully complete the permitting and siting aspects of the project as proposed and maintain compliance with applicable rules and regulations.

6b. Technical/Operational Area

- Items related to the long-term operational performance, reliability, and maintainability of the proposed generating alternatives.

6c. Project Execution Area

- Items related to the exceptions stated to the RFP and the impact of those exceptions.
- Items that relate to the Proposer's ability to complete the development, construction, and operational aspects of the project as proposed.

Proposals that exhibit strong potential in the economic evaluation, but are unclear in certain non-economic evaluation areas, may be considered for a Panel Review. The Panel Review, if necessary, would provide for an exchange between the Proposer(s) and FPL panelists regarding the non-economic evaluation areas. This would allow for a more complete exchange of information in the important areas. Proposers will be notified individually if a need for a Panel Review is indicated, and a mutually convenient time will be arranged.
The specific key parameters for each of these 3 areas are presented in Tables D.1 - 1 through D.1 – 3 that follow.

Step 7: Best and Final Offer Evaluation

After the economic results from Step 5 and the non-economic results from Step 6 are developed, the overall economic and non-economic profile of each resource plan based on a single proposal or portfolio of proposals will be examined and compared to the resource plan that includes FPL's NPGU. At that time, FPL will decide whether it will select a Short List of Proposers. If so, FPL may request from these Short Listed Proposers a Best and Final Offer ("BAFO"). In this case, FPL would then evaluate these BAFOs to develop the final economic and non-economic evaluations.

If the results of the evaluation indicate that the additional step of selecting a Short List of Proposers is not necessary or appropriate, FPL will base its decision on the evaluation (economic and non-economic) performed on the original proposals.

Step 8: Final Selection

The results of FPL's economic and non-economic evaluation will be presented to an FPL Management Review Team. The Management Review Team will then make a selection based on sound business practices and the best interests of FPL's customers.

D.2 Transmission Integration and Losses

A. Overview

In its evaluation of proposals received in response to this RFP, FPL will be evaluating five transmission-related costs associated with FPL's transmission system for individual proposals or for portfolios of proposals. These five costs are:

1) transmission interconnection costs (as applicable);
2) third party transmission service costs (as applicable);
3) transmission integration costs;
4) costs of transmission system losses; and
5) cost impacts of the resource plans on maintaining a balance between load and generation in the Southeastern Florida region (*i.e.*, Miami-Dade and Broward counties).

Noting that the transmission interconnection and third party transmission service costs are to be provided by each Proposer for their individual proposal(s), each of these 5 categories of transmission-related costs are discussed below.

1. Transmission Interconnection Costs (as applicable)

As discussed in Appendix C, Form # 5, a Proposer whose proposal is based partially or totally on generators that need to be constructed and connected to a transmission system must include all costs of this interconnection in the proposal's Guaranteed Capacity Payment. In addition, these interconnection costs must be separately broken out on Form # 5 so that FPL may judge the reasonableness of this estimate. FPL reserves the right to review and, if it deems necessary, to adjust this estimate accordingly to provide a more accurate interconnection cost based on FPL's knowledge and experience with the transmission system. Proposers will be notified of any such adjustments affecting their proposal(s).

All proposals that are based partially or totally on generators that need to be constructed and connected to the transmission system must also demonstrate per instructions on Form # 5 that they have a valid completed application for Generator Interconnection Service ("GIS") in the FPL GIS Queue, or with the applicable third party if the new generator is to be connected to a third party's transmission system.

The process for requesting GIS and having a completed GIS application on the FPL system is delineated in FPL's Open Access Transmission Tariff.

2. Third Party Transmission Service Costs (as applicable)

As discussed in Appendix C, regarding Form # 5, to the extent the generator(s) is connected to the transmission system of a third party, the Proposer shall include any and all third party transmission service costs in the Guaranteed Capacity Payment.

In addition, the Proposer shall state on Form # 5 whether such long-term transmission rights for third party transmission service has been requested and/or already procured for a portion of or all of the generation capacity being offered. To the extent a request for such long – term firm transmission rights has been made, but not yet procured, the Proposer shall provide all available studies and information associated with such request(s).

Finally, the Proposer shall also state on Form # 5 the transmission losses associated with the third party transmission service which are accounted for as the Proposer developed the Total Guaranteed Firm Capacity (as delivered to FPL's system) values on Form # 4.

3. Transmission Integration Costs

The transmission integration costs are based on all modifications (new facilities and facility upgrades) to the FPL transmission system that are necessary to physically transfer the proposed power from the FPL System Receipt Point to the load center consistent with reliability standards for 2019 conditions. The latest available Florida Reliability Coordinating Council (FRCC) peak load flow case representing the year 2019 (updated as necessary to reflect the latest available information) will be used as the basis for determining the transmission integration modifications needed. Once these modifications are determined, costs for these modifications will be estimated. These costs will then be assigned to the resource plan in question. The process of determining the needed transmission integration modifications generally consists of three steps.

Integration Cost Step 1: Identify Needed New/Upgraded Facilities

The first step is to perform screening studies to identify new facilities and facility upgrades that would be needed to integrate the proposals, portfolios of proposals, and/or the NPGU in each resource plan into the transmission system as a network resource for FPL. The type of studies that will be performed are considered screening type studies since they are not as comprehensive as studies that are normally performed for a specific request for transmission service. However, the screening type studies are sufficient to provide a reasonable estimate of the upgrades and facilities necessary to integrate each portfolio into the FPL system meeting the same reliability standards for comparison purposes. The analysis will assure that the FPL transmission system is planned with sufficient capability such that FPL can serve its customers and meet its transmission service obligations beginning in the year 2019 consistent with NERC, FRCC, and FPL standards.

Each of the resource plans will be subjected to contingency screening of all transmission elements and generators, and the transmission system is monitored for violations of NERC, FRCC, and FPL standards. Contingency screening tests will be performed at summer peak load conditions with all FPL generators/facilities assumed available and economically dispatched. Further, the generator deemed most critical to that case will be assumed to be unavailable, and the remaining FPL generators will be dispatched to mitigate, if practicable, violation of reliability criteria for all contingencies tested. Violations of reliability criteria found on the FPL system are resolved by acceptable remedial action (*e.g.*, switching), facility upgrades, or by new facilities, as appropriate. All proposed solutions will be subsequently introduced into the appropriate case and tested in order to verify the completeness of the solution.

During these studies, potential violations may be noticed on third party transmission systems. Should that occur, the following actions will be taken. The observance of such potential violations and the details surrounding these events will be communicated to the Proposer whose proposal is associated with the third party transmission system in question. Since the mitigation measures employed for the potential violations on third party systems will be at the discretion of, and based on the expertise of, third parties for their own transmission systems, identified potential violations will need to be communicated by the Proposer to the third party transmission system owner. Resolution of potential violations will be necessary if the proposal is selected to potentially meet FPL's need. As a result, any upgrades or facilities required on a third party system and attendant costs must be developed and provided by the Proposer so that they may be taken into consideration in the final evaluation. It is possible that a potential violation could be attributable in part to the portfolio combination of proposals being reviewed (*e.g.*, violation on transmission system X of Proposal A is aggravated by existence of Proposal B on FPL system). Analysis of this type would require a coordinated effort and the involvement of multiple parties.

Integration Cost Step 2: Determine Total Cost of Needed Facilities

Once a list of new facilities and upgrades on the FPL system required for integration is identified, the second step of the evaluation process of developing cost estimates for the new and upgraded transmission facilities commences. Based on the need for incremental transmission facilities identified in each resource plan, a cost estimate for the facilities is developed in a consistent manner for each resource plan. The estimates will be based on engineering judgment and readily available cost information, including cost information previously obtained from equipment manufacturers for transmission reinforcements of the type and capacity required. The estimates do not involve any field inspections, or detailed analysis of the type that would be performed in response to a specific request for interconnection or transmission service, but are adequate for their intended purpose.

Integration Cost Step 3: Develop Monthly Cash Flows

The final step in the process involves transforming the total transmission integration cost for resource plan developed in Step 2 into an estimated monthly cash flow (including AFUDC, as appropriate) of the costs for the transmission projects. This will allow projected annual integration costs to be accounted for each resource plan.

4. Costs of Transmission System Losses

Each proposal, portfolio of proposals, and/or the NPGU in the resource plans will contain capacity additions at specific locations in relation to the FPL transmission system. Therefore, each resource plan will present a unique transmission loss impact when combined with the existing FPL transmission system. The difference in the economic impacts between resource plans related to losses will be estimated and applied in the economic comparison of resource plans.

There are two types of losses that comprise total transmission losses for the system. In the analysis of the first type of loss, the generation capacity required to compensate for transmission losses is based on losses during peak load conditions. The second type of loss, energy losses that occur over the entire year, will be estimated based on losses during peak load and average system load conditions.

Transmission losses will vary from year-to-year with load growth, transmission system additions, and resource additions. It is not practicable to predict the amount of such variations due to the almost infinite combinations of future scenarios. It is, however, both certain and practical to assess the impact each portfolio would have in the 2019 time frame of operation. Losses for all future years are calculated based on expected 2020 system conditions, while only accounting for term-of-service-related changes in a particular resource plan over time as discussed below.

The losses for a given resource plan are determined, and costs are assigned to these losses, in a 3-step procedure discussed below. This discussion utilizes a hypothetical example to explain the loss evaluation and cost assignment methodologies. In this example, it is assumed that a hypothetical resource plan has a 1,200 MW proposed purchase for 20 years starting in 2019. At the end of the 20-year purchase term, the proposed 1,200 MW purchase capacity is replaced by filler units.

Cost of Losses Step 1: Calculation of Peak Load and Average Load Losses

a) <u>Peak Load Losses</u>

The required FPL transmission system integration upgrades will be incorporated into the FRCC load flow base case (updated with the latest available information), resulting in a modified, resource plan-specific load flow case. The modified load flow case is set up with the proposal, portfolio of proposals, and/or the NPGU on-line at full output, and the remaining system resources are dispatched economically. The losses (MW) <u>at the peak load hour</u> on the FPL transmission system (Peak Load Losses) are then calculated.

The resource plan associated with the lowest system Peak Load Losses for the year 2019 will be designated as the "reference" resource plan for both the 2019 Peak Load Losses and Average Load Losses analyses. The difference between system Peak Load Losses associated with each resource plan and with the reference resource plan will be calculated for 2019.

Starting with the year 2019, the total losses will remain constant for each resource plan for the 2019 – on time period until one of the components (proposal, portfolio of proposals, and/or the NPGU) reaches the end of its proposed term-of-service. If there are no changes to the reference resource plan during this period, the difference in transmission losses between the specific resource plan being evaluated and the reference resource plan will also be unchanged over this period.

In the example, the MW differences in system Peak Load Losses associated with the hypothetical resource plan and with the reference resource plan can be seen in Column (8) of Table D.2 – 1 below.

For resource plans (including the actual reference resource plan) that have components whose proposed terms-of-service end prior to the end of the analysis period (as is the case with this hypothetical resource plan), the resource plan-specific load flow case mentioned above will be further modified. This additional modification will reflect the termination of a specific component along with a corresponding adjustment to the FPL load. The system Peak Load Losses associated with only the resource plan's remaining components are first calculated. Then, in order to compensate for the loss of the expired component's capacity, an equal amount of Filler unit capacity and load is introduced. This Filler unit capacity is assumed to have losses equal to FPL's current system average transmission losses (1.85%).[1]

The losses associated with the reference resource plan are subtracted from the system Peak Load Losses associated with the remaining resource plan components, plus the Filler unit losses. The resulting system Peak Load Loss value associated with the resource plan is carried forward until another component of the resource plan reaches the end of its proposed term-of-service (if applicable).

[1] Note that the FPL system average transmission losses mentioned here are not the same as the Average Load Losses discussed later in this section.

Table D.2 - 1

Peak Load Losses Calculation for:

Example: For 2019, a 1,200 MW proposal for 20 years

	Year	(1) Proposal 1 (1200 MW)	(2) Filler Capacity Needed to replace Resource Plan's Expired Components (MW)	(3) Filler Capacity Losses (%)	(4) = (2) * (3) Filler Capacity Losses (MW)	(5) FPL Transmission System Losses with Resource Plan's Remaining Components (MW)	(6) = (4) + (5) FPL Transmission System Losses with Resource Plan's Remaining Components + Filler Capacity Losses (MW)	(7) FPL Transmission System Losses with the Reference Resource Plan (MW)	(8) = (6) - (7) Difference in FPL Transmission System Losses between Resource Plan In Question and Reference Resource Plan (MW)
1	2019	1,200	-	1.85%	0	475	475	466	9
2	2020	1,200	-	1.85%	0	494	494	474	20
3	2021	1,200	-	1.85%	0	486	486	483	3
4	2022	1,200	-	1.85%	0	514	514	507	7
5	2023	1,200	-	1.85%	0	567	567	546	21
6	2024	1,200	-	1.85%	0	567	567	574	(7)
7	2025	1,200	-	1.85%	0	567	567	574	(7)
8	2026	1,200	-	1.85%	0	567	567	574	(7)
9	2027	1,200	-	1.85%	0	567	567	574	(7)
10	2028	1,200	-	1.85%	0	567	567	574	(7)
11	2029	1,200	-	1.85%	0	567	567	574	(7)
12	2030	1,200	-	1.85%	0	567	567	574	(7)
13	2031	1,200	-	1.85%	0	567	567	574	(7)
14	2032	1,200	-	1.85%	0	567	567	574	(7)
15	2033	1,200	-	1.85%	0	567	567	574	(7)
16	2034	1,200	-	1.85%	0	567	567	574	(7)
17	2035	1,200	-	1.85%	0	567	567	574	(7)
18	2036	1,200	-	1.85%	0	567	567	574	(7)
19	2037	1,200	-	1.85%	0	567	567	574	(7)
20	2038	1,200	-	1.85%	0	567	567	574	(7)
21	2039	-	1,200	1.85%	22	567	589	574	16
22	2040	-	1,200	1.85%	22	567	589	574	16
23	2041	-	1,200	1.85%	22	567	589	574	16
24	2042	-	1,200	1.85%	22	567	589	574	16
25	2043	-	1,200	1.85%	22	567	589	574	16
26	2044	-	1,200	1.85%	22	567	589	574	16
27	2045	-	1,200	1.85%	22	567	589	574	16
28	2046	-	1,200	1.85%	22	567	589	574	16
29	2047	-	1,200	1.85%	22	567	589	574	16
30	2048	-	1,200	1.85%	22	567	589	574	16
31	2049	-	1,200	1.85%	22	567	589	574	16

b) Average Load Losses

Another separate set of load flow cases is then created for each resource plan. This second set of load flow cases represent specific portfolios in 2019 - on, under FPL's average system load (*i.e.*, 60% of peak) and typical operation of FPL's system (*e.g.*, peaking generation type components off-line). For each resource plan, the transmission system is modified to include the same transmission upgrades required for that resource plan as applied to the load flow cases used for the Peak Load Losses evaluation. This system representation is used to calculate the transmission system losses on the FPL system at average system load (Average Load Losses) for each resource plan including the reference resource plan defined in the Peak Load Losses calculations for years 2019 - on.

The difference between system Average Load Losses of each evaluated resource plan and the reference resource plan will be calculated for 2019. Thereafter, the difference amount is carried forward for each year until one of the components making up the resource plan (or one of the components in the reference resource plan) reaches the end of its proposed term-of-service.

In the example, the differences between the system Average Load Losses associated with the hypothetical resource plan and with the reference resource plan can be seen in Column (8) of Tables D.2 – 2 below.

For resource plans that have components whose proposed terms-of-service end prior to the end of the analysis period, and which would have been on-line in the typical operation of the system at FPL's system average load, that component would be replaced with Filler unit capacity. The loss calculations in these instances will be based on the same 2019 load flow case, but with the FPL load reduced by the amount of expired capacity and the existing FPL resources and the remaining resource components dispatched to represent typical operation of FPL's system (*e.g.*, peaking type components off-line at this load level). In those circumstances in which a component is not typically in operation at FPL's average system load and whose term-of-service ends prior to the end of the analysis period, no Filler unit capacity is introduced for this analysis.

Table D.2 - 2

Average Load Losses Calculation for:

Example: For 2019, a 1,200 MW proposal for 20 years

		(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
					= (2) * (3)		= (4) + (5)		= (6) - (7)
	Year	Proposal 1 (1200 MW)	Filler Capacity Needed to replace Resorce Plan's Expired Components (MW)	Filler Capacity Losses (%)	Filler Capacity Losses (MW)	FPL Transmission System Losses with Resource Plan's Remaining Components (MW)	FPL Transmission System Losses with Resource Plan's Remaining Components Filler Capacity Losses (MW)	FPL Transmission System Losses with the Reference Resource Plan (MW)	Difference in FPL Transmission System Losses between Resource Plan in Question and Rdference Resource Plan (MW)
1	2019	1,200	-	1.85%	0	248	248	238	10
2	2020	1,200	-	1.85%	0	248	248	248	0
3	2021	1,200	-	1.85%	0	248	248	241	7
4	2022	1,200	-	1.85%	0	246	246	251	(5)
5	2023	1,200	-	1.85%	0	246	246	272	(26)
6	2024	1,200	-	1.85%	0	246	246	273	(27)
7	2025	1,200	-	1.85%	0	246	246	273	(27)
8	2026	1,200	-	1.85%	0	246	246	273	(27)
9	2027	1,200	-	1.85%	0	246	246	273	(27)
10	2028	1,200	-	1.85%	0	246	246	273	(27)
11	2029	1,200	-	1.85%	0	246	246	273	(27)
12	2030	1,200	-	1.85%	0	246	246	273	(27)
13	2031	1,200	-	1.85%	0	246	246	273	(27)
14	2032	1,200	-	1.85%	0	246	246	273	(27)
15	2033	1,200	-	1.85%	0	246	246	273	(27)
16	2034	1,200	-	1.85%	0	246	246	273	(27)
17	2035	1,200	-	1.85%	0	246	246	273	(27)
18	2036	1,200	-	1.85%	0	246	246	273	(27)
19	2037	1,200	-	1.85%	0	246	246	273	(27)
20	2038	1,200	-	1.85%	0	246	246	273	(27)
21	2039	-	1,200	1.85%	22	246	268	273	(5)
22	2040	-	1,200	1.85%	22	246	268	273	(5)
23	2041	-	1,200	1.85%	22	246	268	273	(5)
24	2042	-	1,200	1.85%	22	246	268	273	(5)
25	2043	-	1,200	1.85%	22	246	268	273	(5)
26	2044	-	1,200	1.85%	22	246	268	273	(5)
27	2045	-	1,200	1.85%	22	246	268	273	(5)
28	2046	-	1,200	1.85%	22	246	268	273	(5)
29	2047	-	1,200	1.85%	22	246	268	273	(5)
30	2048	-	1,200	1.85%	22	246	268	273	(5)
31	2049	-	1,200	1.85%	22	246	268	273	(5)

Cost of Losses Step 2: Calculation of Peak Hour Capacity Loss Costs:

The cost of peak hour capacity losses associated with a resource plan is the product of the annual difference in the Peak Load Losses between a resource plan and the reference resource plan (calculated in Step 1) multiplied by a proxy purchase cost ($5/kw-month), and then escalated annually throughout the analysis period. This proxy purchase cost represents the economic value needed to bring this reference plan into equivalence with the reference resource plan.

An example of this calculation for the hypothetical resource plan is shown below in Table D.2 – 3.

An annual peak hour capacity loss cost is calculated for all years starting in 2019 and the annual costs are then present valued and summed. The sum of these present valued costs represents the difference in CPVRR cost of peak hour capacity losses associated with the resource plan relative to the reference resource plan.

Cost of Losses Step 3: Calculation of Annual Energy Loss Costs:

Both the differences for the Peak Load Losses and Average Load Losses between a resource plan and the reference resource plan (calculated in Step 1) are first converted to energy (MWh) values. The Peak Load Loss value is multiplied by 876 hours each year (representing 10% of the annual 8,760 hours) to derive an "on-peak" energy loss (MWh) value. These on-peak MWh values are then multiplied by projected on-peak marginal energy prices to derive on-peak energy loss costs for each resource plan relative to the reference resource plan.

Similarly, the Average Load Losses value is multiplied by an appropriate (to the type of capacity being offered in the resource plan) number of hours to derive an "off-peak" energy loss (MWh) value. These off-peak MWh values are then multiplied by projected off-peak marginal energy prices to derive off-peak energy loss costs for each resource plan relative to the reference resource plan.

These annual on-peak and off-peak energy loss costs are then summed to derive a total annual energy loss cost for each resource plan relative to the reference resource plan. This total annual energy loss cost is calculated for all years starting in 2020. These annual costs are then present valued and summed. The sum of these present valued costs represents the difference in the CPVRR cost of energy losses associated with the resource plan relative to the reference resource plan.

Tables D.2 – 3 and D.2 - 4 present an example of this calculation for the hypothetical resource plan. In Table D.2 – 4, a set of marginal energy costs based on FPL's designated Fossil Fuel Price Forecast is used in this example.

Table D.2 - 3

Calculation of Costs for Peak Hour Capacity Losses (MW) for:

Example: For 2019, a 1,200 MW Proposal for 20 years

Discount Rate =	7.51%
Purchase Proxy Starting Cost ($/kw) =	$5.00
Annual Escalation Rate for Proxy Purchase =	2.5%

		(1)	(2)	(3)	(4)	(5)
					=(1)*(3)*12	=(2)*(4)
	Year	Proxy Purchase Cost ($/kw-mo)	Discount Factor	Peak Load Loss (MW)	Peak Hour Capacity Loss Cost Nominal ($ 000)	Peak Hour Capacity Loss Cost NPV ($ 000)
	2015	$0.00	1.000	0	$0	$0
	2016	$0.00	0.930	0	$0	$0
	2017	$0.00	0.865	0	$0	$0
	2018	$0.00	0.805	0	$0	$0
1	2019	$5.00	0.749	9	$553	$414
2	2020	$5.13	0.696	20	$1,215	$846

5. Cost Impacts Regarding Maintaining a Balance Between Load and Generation in the Southeastern Florida Region

The location of proposed generation capacity in each resource plan will be evaluated in regard to how it is projected to affect FPL's ability to maintain a balance between load and generation in the Southeastern Florida region consisting of Miami-Dade and Broward counties. The analysis approach that will be used is the same as has been utilized in a number of FPL's filings over the last several years including nuclear cost recovery and DSM. The projected costs of maintaining this balance solely through new transmission expenditures will first be developed. Then each resource plan will be analyzed to determine if the proposed location of the generation resources would avoid/defer any of these projected transmission expenditures. If so, then the resource plan may be credited with the benefit of avoiding/deferring the costs of these transmission projects.

D.3 Net Equity Adjustment

A. Explanation of Equity Adjustment

In order to fairly evaluate the total cost of competing resource plans, FPL will consider the impact that the potential selection of each resource plan would have on FPL's overall capital structure. FPL's NPGU assumes financing of incremental costs at 59.62% equity, 40.38% debt, and these financing costs are included in the total cost of FPL's NPGU.

Consistent with that approach, an adjustment will be made to the total cost of other resource plans containing purchased power obligations to reflect the fact that such obligations draw upon the debt capacity of FPL and, all other things being equal, must be offset by increasing the ratio of equity in FPL's capital structure. This is necessary to ensure that resource plans are compared against one another in a manner that is neutral relative to FPL's capital structure. Rating agencies explicitly evaluate purchase power obligations and, based on that examination, the rating agencies attribute a portion of the net present value (NPV) of the obligations under each power purchase agreement to the utility's balance sheet as a debt equivalent. The effect of this adjustment is to increase the relative share of debt and debt-like instruments in the capital structure. Therefore, FPL will calculate the incremental cost of the equity required to rebalance the capital structure at 59.62% equity, 40.38% debt to obtain a complete assessment of the related costs to FPL associated with each resource plan.

Standard & Poor's ("S & P") methodology will be used to calculate the debt equivalent that would be added to FPL's capital structure. S & P begins by taking the NPV of the annual capacity payments over the life of the power purchase contract using a 7% discount factor. To determine the debt equivalent, the NPV is then multiplied by a risk factor. Based on the guidelines provided by S & P for utilities with a clause recovery mechanism (such as is the case for FPL), a 25% risk factor will be used to calculate the debt equivalent.

Once the debt equivalent has been determined, the amount of equity required to rebalance the capital structure will be calculated. The equity adjustment represents the net present value of the incremental cost of equity (versus debt) required to rebalance the capital structure. A detailed example of the calculation of the equity adjustment is presented in Table D.3 – 1 at the end of this section.

B. Mitigating Factors

While the S & P methodology takes a broad look at the debt equivalence of purchase power obligations, there may be other factors which may be considered as mitigating the effect of such purchased power obligations. The following subsections discuss those factors that, in FPL's review, may offer some mitigation and can be quantified. These factors will be reflected as credits in the development of a modified or net equity adjustment factor.

1) Mitigation Offered by Completion Security

When FPL enters into a purchased power agreement (PPA) associated with a new unit to be constructed, the Proposer will provide Completion Security to address the delivery risks associated with completing the project. Many of these risks can be combined and represented as the risk of delivering less capacity than that proposed, and upon which the selection was made and a PPA was executed. Under an FPL self-build option, there is some small probability that such an event might occur, and that impact might not be mitigated by FPL's contractual arrangements. If this occurred and it was determined by the FPSC that FPL was not imprudent, any incremental cost caused by such a delivery shortage may be allowed to be recovered from FPL's customers.

If this same sequence of events occurred under a PPA associated with a unit to be constructed, in the form contemplated by FPL, the Completion Security could mitigate the impact of those costs on FPL's customers. This would be the source of mitigation provided by the PPA Completion Security that is different from an FPL self-build option.

In order to assess a quantitative value that could be assigned to this mitigation, both the risk of occurrence and the economic magnitude of the occurrence of a delivery shortage must be estimated.

FPL reviewed the history of FPL self-build projects relevant to this RFP to determine the probability of a delivery shortage. These combined cycle projects represented approximately 6,745 MW of planned capacity. The data showed that some projects over-delivered while others under-delivered. As a conservative approach, overages were not allowed to offset shortages. On this basis, a total shortage of 14 MW was seen over the projected approximately 6,745 MW resulting in a probability of delivery shortage of 0.21%.

The economic impact of a delivery shortage can be identified as represented by the Completion Security amount established by FPL. It is noted that this amount could be mitigated by many factors for specific occurrences; *e.g.*, component performance guarantees, engineering - procurement - construction (EPC) guarantees and Liquidated Damages (LD's), but represents a "worst case" value that is conservatively derived and applied to the favor of the Proposer in developing the mitigation credit.

The value of the mitigation provided by a PPA would be the product of the probability of delivery shortage (risk) and the Completion Security amount (magnitude) identified in Section IV of the RFP document.

The following example demonstrates the Completion Security mitigating factor calculation for a proposal based on a new generating unit:

P_{DS} = Probability of FPL Delivery Shortage = 0.21%
CS = Completion Security = $200,000 per MW

CS Mitigation = CS * (P_{DS}) = $200,000* (0.0021) = $420 per MW (Nominal $)

2) Mitigation offered by Performance Security

FPL recognizes that PPA-based capacity, if selected instead of an FPL self-build option, has the potential to provide better performance than that projected for FPL's NPGU at certain times. Therefore, FPL has calculated a Performance Mitigating Factor that attributes an appropriate amount of credit to a PPA for this potential benefit.

The Performance Mitigating Factor is not dependent upon the type or nature of the PPA in question. Instead, it is based on the projected forced outage factor (FOF) of FPL's NPGU in this RFP compared to recent FPL experience with the type of new units installed and operated by FPL that are most similar to the NPGU of this RFP; *i.e.*, combined cycle units. The most recent FPL combined cycle units are: Martin units 3, 4, and 8, Manatee unit 3, Turkey Point unit 5, and West County units 1, 2, and 3.

The actual/projected annual average FOF for these units over their projected life is 1.56%. The projected average annual FOF for FPL's NPGU is 1.1%. Consequently, using the actual/projected annual average FOF for the previous FPL combined cycle units as a possible projection of the actual FOF for the similar, but different, technology of FPL's NPGU, yields a possible FOF annual differential of 0.46%.

This translates to approximately 40 hours per full year (8,760 hours/year x 0.0046 = 40 hours/year) in which the existing units on FPL's system might have to supply energy that is projected to be supplied by the NPGU. Then, using the same projection of FPL system marginal energy costs that is used in the calculation of the Costs of Transmission Losses in Section D.2 of this appendix, a calculation of the replacement energy costs for these 40 hours for each year is made. This annual nominal cost value is then present valued and added to the cumulative present value of these costs from prior years. This calculation is presented in Table D.3 – 2 at the end of this section.

As seen in Table D.3 – 2, the values calculated are on a per MW basis and can vary according to the proposed term of the PPA. The actual Performance Mitigating Factor that will be applied to a PPA will depend both upon the proposed capacity (MW) and the proposed term-of-service.

3) Application

Once the appropriate Performance Mitigating Factor is calculated for a PPA, this mitigating factor, plus the Completion Security Mitigating Factor discussed above, will be subtracted from the Equity Adjustment value to derive a Net Equity Adjustment value for the PPA. This net value will be included in the final economic evaluation of all resource plans that include this PPA.

An example application of the equity adjustment calculation, and the mitigating factors, to provide a net equity adjustment value is presented in the remainder of this section.

C. Example Net Equity Adjustment Calculations

The net equity adjustment calculations that FPL will use in its evaluation of purchased power Proposals received in response to this RFP are explained below using a hypothetical Proposal for 500 MW starting in June 2019 through the end of 2030 at a constant price of $60/kw-yr (or $5/kw-month).

Table D.3 -1 presents the equity adjustment calculation. This is preceded by an explanation by column of the values in Table D.3 - 1. The first of the two mitigating factors is then discussed. Then Table D.3 – 2 presents the calculation of the second of the two mitigating factors. The net equity adjustment value is then calculated.

Explanation of calculation by column:

Column [K] = Projected Annual Capacity Payments in $/kw-year (assuming a constant $5/kw-month payment.)

Column [L] = Projected Annual Capacity Payments in $000 (Projected Annual Capacity Payments in $/kw-year * Proposal's Firm Capacity (MW) * PPA's Firm Capacity Ratio) /12 * number of months capacity is delivered)

Column [M] = Net Present Value (NPV) of the total sum of remaining annual capacity payments with values discounted at the risk factor used by S&P's to value off-balance sheet purchase power obligations.

Example: For 2019: NPV of capacity payments for (2019-2030)
For 2020: NPV of capacity payments for (2020 – 2030)
For 2021: NPV of capacity payments for (2021 – 2030)
Etc:

Column [N] =Total imputed asset value (NPV of capacity payments in Column [3]* S&P Adjustment Factor)

Column [O] =Equity Replaced to Rebalance (Total imputed asset value in Column [4] * Equity ratio)

Column [P] = Equity Adjustment (Column [5]* Equity vs. Debt Cost Difference)
(Where Equity vs. Debt Cost Difference = ((Cost of Equity)/(1- Effective Tax Rate)) – Cost of Debt)

NPV Total is discounted back to the current year (2015 in this example) using the after tax cost of capital discount rate.

Table D.3 - 1

Equity Adjustment Calculation - Example Purchase

	Notes			Notes	
Adjustment Factor	A	25.00%	Disc Rate for Equity Adj (FPL 2014 WACC)	G	7.51%

			CPVRR Equity Adjustment @ WACC (2015 $s) @ 59.6% =			**$17,810**

Notes:

A) Per Standard & Poor's methodology for utilities, such as FPL, that have a clause recovery mechanism
B) FPL target equity ratio
C) FPL effective tax rate
D) FPL average cost of debt
E) Discount applied to Capacity Charges per S&P
F) FPL's allowed ROE
G) FPL incremental WACC (based on B,C,D,F above)
H) Difference between FPL's pre-tax cost of equity and debt
I) Sum of capacity of PPA portfolio
J) Firm capacity ratio of PPAs
K) Annual capacity payments calculated by multiplying the capacity charge, by the project namplate capacity and the firm capacity ratio of 100%
L) Annual capacity payments of PPA's
M) PV of net capacity payments discounted at FPL's average cost of debt
N) Per S&P methodology, apply a 25% adjustment factor for utilities with clause recovery mechanisms to the NPV of capacity payments
O) Equity required to rebalance due to the additional imputed debt is calculated by multiplying the debt equivalence by the target equity ratio
P) The equity adjustment is calculated as the equity replaced to rebalance, multiplied by the difference between the cost of equity and the pre-tax debt cost
Q) The CPVRR of the equity adjustments discounted at WACC. Represents the additional equity required to maintain the capital structures ratio considering the PPA as debt.

Completion Security Mitigation Example:

The Completion Security Mitigating Factor would be credited by applying the amount previously calculated:

CS mitigation/MW * Capacity * Net Present Value Factor for the year 2019 = Completion Security Mitigation Factor

$420/MW * 500 MW = $210,000 (Nominal $) or
$210,000 * 0.749 = $157,290 (NPV $)

Performance Mitigation Example:

The Performance Mitigation value, in terms of $ per MW, is presented in the following table.
In the table above, a 500 MW PPA with an in-service date of 2019 and a term through the end of 2030 would have a Performance Mitigation amount of:

500 MW * $11,537/MW = $ 5,768,500 (NPV $)

Net Equity Adjustment Example:

In this example, the Completion Security Mitigation amount and the Performance Mitigation amount would be subtracted from the Equity Adjustment to yield a Net Equity Adjustment value for a resource plan that included this PPA of:

$17,810,000 - $157,290 - $5,768,500 = $11,884,210 (NPV $)

Table D.3 - 2

Performance Mitigating Factor Calculation: for Bid with 2019 In-Service Date
(Note: Values shown are "per MW" values)

Assumptions:

Capacity level (MW) =	1
Historical Average FOF value for CC units =	1.56%
Projected Annual FOF value for NPGU =	1.10%
Average Annual FOF "overage" for FPL CCs =	0.46%

		(1)	(2)	(3)	(4) = (2) x (3)	(5) = (1) x (3)	(6)

APPENDIX E

Changes in Key Forecasts and FPL's Resource Plan from FPL's 2014 Ten-Year Site Plan

(This page is left intentionally blank.)

FPL's 2014 Ten-Year Site Plan (Site Plan) was filed with the Florida Public Service Commission (FPSC) in April 2014. This Site Plan, presented in Appendix A of this RFP document, addressed FPL's resource planning work during the year 2013 and the first quarter of 2014. Since the first quarter of 2014, a number of changes have occurred in regard to the forecasts that are used in FPL's resource planning work. Largely as a result of these changes to forecasts, FPL's current resource plan has also changed. The changes to these forecasts and FPL's resource plan will be presented in FPL's 2015 Site Plan that will be filed with the Florida Public Service Commission on April 1, 2015.

For the benefit of potential bidders to this capacity RFP, two tables are presented below. Table E - 1 summarizes changes in key forecasts from those used in the 2014 Site Plan work. Table E – 2 summarizes key changes in FPL's resource plan through the year 2019 (the year for which capacity proposals are being sought with this RFP).

Table E - 1

Key Changes in Forecasts		
Item	**Ten Year Site Plan**	**Current**
Date of Load Forecast	10/1/2013	10/14/2014
Vero Beach load	Included in FPL's load forecast	Not Included in FPL's load forecast
Date of Fuel Forecast	10/7/2013	11/3/2014
Below are the forecasted firm gas prices for 2019 from the two fuel forecasts:		
- 2019 FGT Firm Gas Price	$6.15/MMBTU	$4.70/MMBTU
- 2019 Gulfstream Gas Price	$6.13/MMBTU	$4.65/MMBTU
- 2019 New Pipeline Gas Price	$6.14/MMBTU	$4.69/MMBTU

As shown in Table E – 1, the October 2014 load forecast has now replaced the October 2013 load forecast that was used in the resource planning work that led to the 2014 Site Plan. The new load forecast no longer assumes that FPL will serve the electrical load of Vero Beach. In regard to the Summer 2019 peak load, the new October 2014 load forecast is approximately 150 MW higher than the October 2013 load forecast.

Similarly, the November 2014 fuel cost forecast has now replaced the October 2013 fuel cost forecast that was used in the resource planning work that led to the

2014 Site Plan. As shown in the comparison of forecasted natural gas values for the year 2019, projected natural gas prices are now lower than previously forecast.

In addition, FPL's resource plan has changed from that presented in its 2014 Site Plan. Table E – 2 presents the key changes in FPL's resource plan through the year 2019.

Table E - 2

Key Changes in FPL's Resource Plan Through 2019
(presented in approximate chronological order)

Item	2014 Site Plan	Current
FPL DSM Additions (approx. MW/year)	34	53
Existing GT Replacement	Occurs by the end of 2018; Net effect of approx. 255 MW capability reduction	Occurs by the end of 2016; Net effect of approx. 40 MW capability reduction
Cedar Bay Expiration Date (250 MW)	12/31/2024	12/31/2016
New Utility Scale Solar	No additional solar	3 - 74 MW (nameplate AC) PV facilities by the end of 2016.
2019 Unit (Summer MW)	1,269 MW CC	1,622 MW CC (FPL's NPGU)

FPL's resource plan now shows an increase in annual DSM implementation (in terms of Summer MW peak load reductions) from approximately 34 MW/year assumed in FPL's 2014 Site Plan to approximately 53 MW/year. This is consistent with the FPSC's decision in the 2014 DSM Goals docket.

In its 2014 Site Plan, FPL projected that, for environmental reasons, it would have to retire all of its existing gas turbines (GTs) in Broward County and replace part of that capacity with new combustion turbines (CTs) by the end of 2018. The projected impact of this would have been a net loss of 255 MW. FPL currently projects that it is cost-effective to retire most of its existing GTs at its two Broward County sites (Lauderdale and Port Everglades) and its Lee County (Ft. Myers) site, and partially replace this peaking capacity with new CTs at its

Lauderdale and Ft. Myers sites. In addition, FPL's two existing CTs at its Ft. Myers site will be upgraded to produce more capacity. All of this "GT replacement" work is projected to be completed by the end of 2016.
FPL anticipates terminating its existing power purchase agreement for 250 MW of coal-fired capacity from the Cedar Bay generating facility at the end of August 2015 as a result of a Purchase and Sale Agreement between FPL and Cedar Bay Generating Company, L.P. FPL would then own the unit starting on September 1, 2015. FPL currently anticipates that it will not need the unit for economic purposes after 2016 and, if that proves to be the case, would retire the unit at that time. FPL filed for FPSC approval of the Purchase and Sale Agreement in the first quarter of 2015.

FPL will be adding three new photovoltaic (PV) facilities by the end of 2016. Each of the PV facilities will be approximately 74.5 MW (nameplate rating, AC). The new PV installations are projected to be sited in Manatee, Charlotte, and DeSoto counties. The economics of these specific PV projects are aided by the fact that the sites are located close to existing electric infrastructure including tranmission lines and electric substations.

Finally, in its 2014 Site Plan, FPL projected the addition of a 1,269 MW (Summer) combined cycle (CC) unit as a placeholder in 2019 to meet capacity needs beginning in 2019. At the time the 2014 Site Plan was filed, this represented FPL's best self-build generating option for that year. FPL now projects that a 1,622 MW (Summer) CC unit to be its best self-build generating option for 2019. That CC unit is presented in this RFP as FPL's next planned generating unit (NPGU) which will be evaluated with all eligible proposals received in response to this RFP.

* MW values shown in Columns (1) & (2) include, but are not limited to, the following: the completion of the Port Everglades modernization project in 2016, the retirement of 44 of the 48 existing GTs in late 2016, the addition of 5 new CTs at the Lauderdale site and 2 CTs at the Ft.Myers site in late 2016, the addition of 116 MW of firm PV in late 2016, the upgraded capacity of Ft.Myers 3A & 3B in late 2016, and the addition of an unspecified one-year 207 MW PPA in 2018.

** The DSM values shown in Column (6) account for incremental DSM additions as per the 2014 DSM Goals docket for 2015 through 2020, and for projected annual participant attrition in FPL's existing residential load management program.

*** MW values shown in Column (10) represent new generating capacity needed to meet the 20% total reserve margin criterion.

**** MW values shown in Column (12) represent new generating capacity needed to meet the 10% generation-only reserve margin criterion (GRM) which must be met beginning in 2019.

OCEC Unit 1 Plant Specifications

Generating Technology – "Three on One" (3x1) Combined Cycle Configuration:

- Three (3) Advanced Combustion Turbines with Evaporative Coolers
- Three (3) Heat Recovery Steam Generators with Selective Catalytic Reduction System for NO_X control
- One (1) Single-Reheat Steam Turbine

Expected Plant Peak Capacity:

• Summer (95°F / 50% Relative Humidity (RH))	1,622 MW
• Winter (35°F / 60% RH)	1,595 MW

Projected Unit Performance Data:

• Planned Outage Factor	2.2%
• Forced Outage Factor	1.1%
• Equivalent Availability Factor	96.7%
• Resulting Capacity Factor (%)	Approx. 80%
• Avg. Net Operating Heat Rate (Base operation @ 75°F, 100%)	6,304 Btu/kWh
• Annual Fixed O&M[1]	$16.89/kW-yr
• Variable O&M - excluding fuel[2]	$0.28/MWh

Fuel Type and Base Load Typical Usage @ 75°F:

• Primary Fuel	Natural Gas
• Natural Gas Consumption	9,432,429 scf/hr[3]
• On Site Back Up Fuel	Light Fuel Oil
• Light Fuel Oil Consumption	68,497 gal/hr

Expected Base Load Air Emissions Per Combustion Turbine/Heat Recovery Steam Generator @ 75°F (Baseload):

	Natural Gas	Light Fuel Oil
• NO_x (@15% O_2)	2 ppmvd[4]	8 ppmvd
• CO	5 ppmvd	10 ppmvd
• SO_2	< 0.0003 lb Sulfur/100 cubic feet	<0.0015% Sulfur

Water Balance:

- Primary Water Source – Floridan Aquifer

Linear Facilities:

- One (1) new natural gas pipeline lateral
- No new linear transmission facilities – connect into adjacent 500 kV corridor

---

[1] Annual fixed O&M value includes capital replacement costs and fixed O&M presented as a levelized value to year 2019
[2] Variable O&M represents the value for year 2019
[3] Standard cubic feet per hour
[4] Parts per million volumetric dry

Re: FRCC review of Florida Power and Light's Okeechobee County Energy Center Interconnection and Integration Request

Dear Pedro:

The Florida Reliability Coordinating Council's (FRCC) Transmission Working Group (TWG), and Stability Working Group (SWG) have evaluated and reviewed the Florida Power and Light (FPL) proposed Okeechobee Combined Cycle Unit Generation Interconnection Service Request (GISR) to serve FPL native load. The analyses conducted by the TWG, SWG and FPL for the interconnection and integration plan for FPL's Okeechobee County Energy Center (OCEC) are based on the 2014 FRCC databank, modified for planned facilities that resulted from the 2014 Long Range Study.

The OCEC, located in Okeechobee County, Florida, is comprised of three (3) natural gas fired Combustion Turbine (CT) generators and one (1) Steam Turbine (ST) generator with a total net output of 1652 MW for summer and 1625 MW for winter. The OCEC will be interconnected to the FPL transmission system by looping FPL's existing Martin-Poinsett 500kV line into a new 500 kV Okeechobee substation at the plant site. The project has a proposed in-service date of June 1, 2019.

The TWG evaluation found that FPL's steady state contingency analysis was comprehensive and complete. The analyses evaluated facilities 69 kV and above. Under normal operating conditions all facilities remained within applicable ratings. Both the FPL and the TWG contingency analyses identified potential 3rd party impacts of OCEC on the transmission system within the FRCC Region which have been addressed with appropriate remedies provided by the members of the TWG. A review of the short circuit analysis has also shown that there are no short circuit concerns from the OCEC.

In addition to the steady state and short circuit analyses, the SWG reviewed FPL's stability analyses. The dynamic simulations showed a stable response at both Peak and 50% load levels for planning events required to be analyzed by NERC Reliability Planning Standards.

FRCC
Florida Reliability Coordinating Council, Inc.

FLORIDA RELIABILITY COORDINATING COUNCIL, INC.
3000 BAYPORT DRIVE, SUITE 600
TAMPA, FLORIDA 33607-8410
PHONE 813.289.5644 • FAX 813.289.5646
WWW.FRCC.COM

A Power transfer-Voltage (PV) sensitivity analysis was also performed to determine potential impacts on the Florida-Southern interface resulting from the loss of the entire combined cycle unit, and the results showed no impact on the future ability to import 3200 MW across the Florida-Southern interface with the addition of OCEC.

Based on the above review and analysis conducted by the TWG and SWG, the FRCC Planning Committee has determined that the proposed interconnection and integration plan for OCEC will be reliable, adequate and will not adversely impact the reliability of the FRCC transmission system.

Sincerely,

Vicente Ordax

VICENTE ORDAX
DIRECTOR OF PLANNING

OCEC Unit 1 Expected Construction Schedule

Milestone	Begin	End
Initiate sequence of HRSG orders (NTP[1] x 3)	Dec, 2015	-
Initiate NTP[1] for steam turbine	Dec, 2015	-
Initiate sequence of CT orders (NTP[1] x 3)	Jan, 2016	-
Receive approvals necessary to begin construction	-	Dec, 2016
Site preparation and install foundations	Mar, 2017	Dec, 2017
Balance of Plant	Mar, 2017	Sep, 2018
Erect HRSGs	Sep, 2017	Sep, 2018

John D. Wilson — Director of Research, Southern Alliance for Clean Energy

1810 16th Street, NW, 3rd Floor
Washington, DC 20009
202-495-0776
wilson@cleanenergy.org

EXPERIENCE

Southern Alliance for Clean Energy
Director of Research, Asheville, North Carolina and Washington, DC, 2007 – present
- Manage technical and regulatory advocacy
- Conduct supporting research and policy development across all program areas

Galveston-Houston Association for Smog Prevention
Executive Director, Houston, Texas, 2001 – 2006
- Member, Regional Air Quality Planning Committee
- Member, Transportation Policy Technical Advisory Committee
- Member, Steering Committee, TCEQ Interim Science Committee
- Awards & recognition from the City of Houston, *Houston Press*, and environmental groups

The Goodman Corporation
Senior Associate, Houston, Texas, 2000 – 2001
- Transportation and Urban Planning Consulting
- Project Manager, Houston Main Street Corridor
- Project Manager, Houston Downtown Circulation Study
- Project Manager, Austin Corridor Planning
- Project Manager, Ft. Worth Berry Street Corridor Initiative

Florida Legislature
Senior Legislative Analyst and Technology Projects Coordinator, Office of Program Policy Analysis and Government Accountability, Tallahassee, Florida, 1997- 1999
- Coordinator, Florida Government Accountability Report, 1999
- Coordinator, Project Management Software Implementation, 1999
- Creator and Editor, *Florida Monitor Weekly*, 1998 - 99
- Author or team member for reports on water supply policy, environmental permitting, community development corporations, school district financial management and other issues – most recommendations implemented by the 1998 and 1999 Florida Legislatures

Florida State University
Environmental Management Consultant, Tallahassee, Florida, 1997
- Project staff, *Florida Assessment of Coastal Trends*, 1997

Houston Advanced Research Center
Research Associate, Center for Global Studies, The Woodlands, Texas, 1992 - 96
- Coordinator, Houston Environmental Foresight, 1993 - 96
- Coordinator, Rio Grande/Rio Bravo Basin Initiative, 1992 - 94
- Secretary, Task Force on Climate Change in Texas, 1992 - 94
- Researcher, *Policy Options: Responding to Climate Change in Texas*, 1992 - 93

US Environmental Protection Agency
Student Assistant, Climate Change Division, Washington, DC, 1991 - 92
- Special Achievement Award, 1991

EDUCATION

Harvard University
Master in Public Policy, John F. Kennedy School of Government, 1992
- Concentration areas: Environment, negotiation, economic and analytic methods

Rice University
Bachelor of Arts, conferred *cum laude*, 1990
- Majors: Physics (with honors) and history

Additional Training and Experience
Spanish language; Advanced computer skills; Served and led political committees for the Sierra Club and Clean Water Action; Certified Master Wildlife Conservationist, Leon County Extension Service

PUBLICATIONS

Expert Witness Testimony

John D. Wilson, Direct Testimony on Behalf of South Carolina Coastal Conservation League and Southern Alliance for Clean Energy, *In the Matter of Petition of the Office of Regulatory Staff to Establish Generic Proceeding Pursuant to the Distributed Energy Resource Program Act, Act No. 236 of 2014, Ratification No. 241, Senate Bill No. 1189,* South Carolina Public Service Commission Docket No. 2014-246-E (December 23, 2014).

Hamilton Davis and John D. Wilson, Joint Direct Testimony on Behalf of South Carolina Coastal Conservation League and Southern Alliance for Clean Energy, *In the Matter of Joint Application of Duke Energy Carolinas, LLC and North Carolina Electric Membership Corporation for a Certificate of Environmental Compatibility and Public Convenience and Necessity for the Construction and Operation of a 750MW Combined Generating Plant Near*

Anderson, SC, South Carolina Public Service Commission Docket No. 2013-392-E (December 10, 2013).

John D. Wilson, Direct Testimony on Behalf of Southern Alliance for Clean Energy, *In the Matters of Georgia Power Company's 2013 Integrated Resource Plan and Application for Decertification of Plant Branch Units 3 and 4, Plant McManus Units 1 and 2, Plant Kraft Units 1-4, Plant Yates Units 1-05, Plant Boulevard Units 2 and 3, and Plant Bowen Unit 6*, Georgia Public Service Commission Docket No. 36498 (May 10, 2013).

John D. Wilson, allowable ex parte briefing on behalf of Southern Alliance for Clean Energy, South Carolina Coastal Conservation League, and Upstate Forever, in *Progress Energy Carolinas, Incorporated's Integrated Resource Plan (IRP)*, South Carolina Public Service Commission Docket NO. 2011-8-E and in *Duke Energy Carolinas, LLC – 2011 Integrated Resource Plan*, South Carolina Public Service Commission Docket NO. 2011-10-E (December 21, 2011).

John D. Wilson, allowable ex parte briefing on behalf of Southern Alliance for Clean Energy, South Carolina Coastal Conservation League, and Upstate Forever, in *South Carolina Electric & Gas Company's Integrated Resource Plan*, South Carolina Public Service Commission Docket NO. 2011-9-E (June 1, 2011).

John D. Wilson, Direct Testimony on Behalf of Southern Alliance for Clean Energy, *In the Matters of Georgia Power Company's Application for Certification of its Demand Side Management Program*, Georgia Public Service Commission Docket No. 31082 (May 7, 2010).

John D. Wilson, Direct Testimony on Behalf of Southern Alliance for Clean Energy, *In the Matters of Georgia Power Company's Application for Approval of its 2010 Integrated Resource Plan*, Georgia Public Service Commission Docket No. 31081 (May 7, 2010).

John D. Wilson, Direct Testimony on Behalf of Environmental Defense Fund, The Sierra Club, Southern Alliance for Clean Energy, and the Southern Environmental Law Center, *In the Matter of Investigation of Integrated Resource Planning in North Carolina – 2009*, North Carolina Utilities Commission Docket No. E-100, Sub 124 (February 19, 2010).

John D. Wilson, Direct Testimony on Behalf of Environmental Defense Fund, the Natural Resources Defense Council, the South Carolina Coastal Conservation League, Southern Alliance for Clean Energy, and the Southern Environmental Law Center, *Application of Duke Energy Carolinas, LLC for Authority to Adjust and Increase Its Electric Rate and Charges,* South Carolina Public Service Commission Docket No. 2009-226-E (November 6, 2009).

John D. Wilson, Direct Testimony & Exhibits on behalf of Southern Alliance for Clean Energy and the Natural Resources Defense Council in *RE: Commission Review of Numeric Conservation Goals Florida Power & Light Company*, Florida Public Service Commission Docket No. 080407-EG, also filed in Dockets 080408-EG through 080413-EG (July 6, 2009).

John D. Wilson, Testimony on behalf of Environmental Defense Fund, Natural Resources Defense Council, Southern Alliance for Clean Energy, and Southern Environmental Law Center in *Application of Duke Energy Carolinas, Inc. for Approval of Save-a-Watt Approach, Energy Efficiency Rider and Portfolio of Energy Efficiency Programs*, North Carolina Utilities Commission Docket No. E-7, Sub 831 (June 19, 2009).

John D. Wilson, Surrebuttal Testimony on Behalf of Environmental Defense, the South Carolina Coastal Conservation League, Southern Alliance For Clean Energy and the Southern Environmental Law Center, In the Matter of *Application of Duke Energy Carolinas, LLC for Approval of Energy Efficiency Plan Including an Energy Efficiency Rider and Portfolio of Energy Efficiency Programs*, South Carolina Public Service Commission Docket No. 2007-358-E (January 28, 2008).

[redacted]

Executive Summary

The reserve margin study performed by Astrape Consulting was requested by Duke Energy Carolinas in response to North Carolina Utilities Commission Order dated October 26, 2011 in Docket No. E -100, Sub 128. The Order requires DEC to perform a comprehensive reserve margin study and include it as part of its 2012 biennial IRP report.

The optimal planning reserve margin for Duke Energy is based on providing an acceptable level of physical reliability and minimizing economic costs to customers. Customers generally expect power to be available 24 hours a day, 365 days a year, but it is economically unreasonable for a load serving entity to maintain enough reserves to meet this expectation. From a physical reliability perspective, Loss of Load Expectation (LOLE) decreases as reserve margin increases. The most common physical metric used in the industry is to target a system reserve margin that meets the one day in 10 year standard which is interpreted as one firm load shed event every 10 years (LOLE = 0.1). A firm load shed event occurs when load plus spinning reserves is greater than available capacity and all options including market purchases and demand response have been exhausted. This results in unserved energy for a firm customer. From an economic perspective, as planning reserve margin increases, the total cost of reserves increases while the costs related to reliability events decline. The economic optimum is defined as the point where the cost of additional reserves plus the cost of reliability events on customers is minimized. For this study, reserve margin is defined as the following:

- Reserve Margin = (Resources – Demand) / Demand
  - Demand is the Average Summer System Peak Load and has not been reduced by Demand Response
  - Resources are defined based on summer ratings and include Demand Response
  - The solar capacity within the study was given a 50% capacity credit while wind was given a 15% capacity credit (consistent with the 2011 IRP)

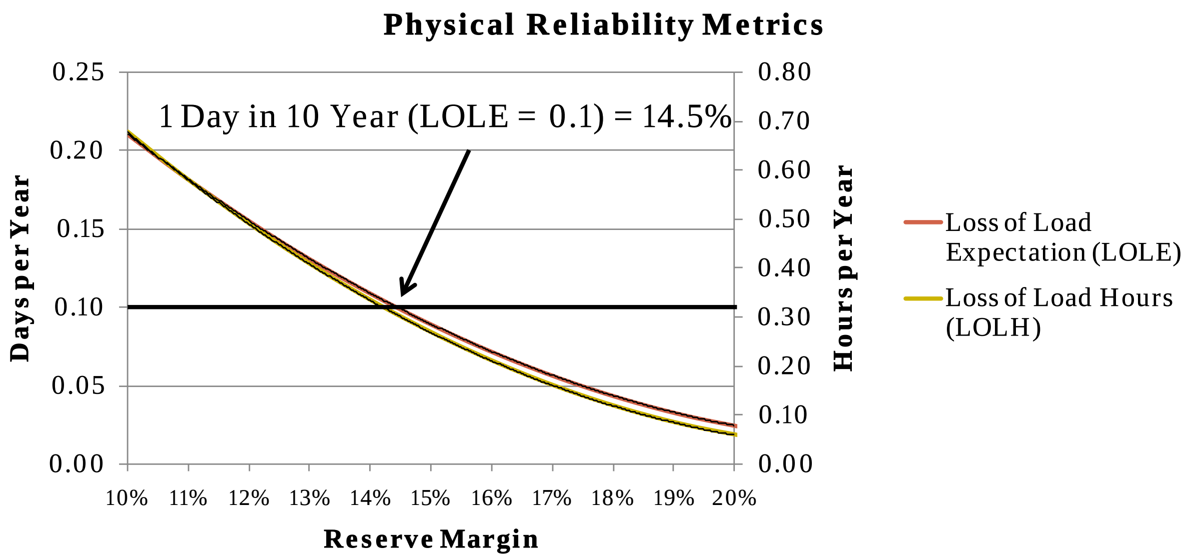
Astrape Consulting has taken a stochastic approach in modeling the uncertainty of weather, economic load growth, unit availability, hydro availability, and transmission availability for emergency tie assistance. Utilizing a multi-area reliability model called SERVM (Strategic Energy and Risk Valuation Model), over 1 million yearly simulations were performed at various reserve margins to calculate the physical reliability metrics and corresponding expected reliability costs. The physical metrics and reliability costs were used to determine an optimal planning reserve margin.

From an economic perspective, the study defines the capacity costs as the annual carrying costs associated with the marginal resource which for this study is a new natural gas combustion turbine. The study defines reliability energy costs as any energy costs the system experiences above the dispatch cost of the marginal resource. These costs include the dispatch of expensive peaking resources such as oil CTs, net imports of expensive market purchases during capacity shortages, and the societal cost of unserved energy.

Summary of Results and Key Insights

The reserve margin that results in 1 day in 10 year LOLE (0.1 days per year) is 14.5% as shown in Figure ES1. Loss of load hours (LOLH) approaches 0.30 hours per year at the 14.5% reserve margin.

Figure ES1. Physical Reliability Metrics



In resource adequacy simulations, firm load shed events are sensitive to inputs due to their infrequent nature. Weather diversity, transmission availability, neighbor reserve levels, and emergency hydro assumptions can shift the 0.1 LOLE reserve margin by several percentage points as shown in the sensitivity section of the report. As an example, emergency hydro assumptions impacted Duke's system LOLE substantially. If the portion of the 1,100 MW hydro capacity that is designated as emergency capacity is available to be used a few hours a month, then the target LOLE reserve margin shifts from 14.50% to 11.25%. This emergency designated block varies by year and month, but during drought conditions, it represents 700-750 MW of unavailable capacity as seen in 2007 and 2008. From a planning perspective, it is difficult to assess the availability of this capacity during drought conditions, and given experience in recent drought years such as 2007 and 2008, it is not prudent to expect this capacity to be available during peak conditions. However, by approaching resource adequacy planning from a more holistic perspective, the target reserve margin is not as sensitive to individual inputs. For this reason, we recommend assessing the economics in addition to the physical reliability metrics. This allows planners to not only assess the comprehensive benefits of incremental capacity, it also allows for better calibration of physical reliability metrics.

The economic reliability assessment which balances the costs and benefits of incremental capacity is seen in Figure ES2 which demonstrates that the long-term minimum cost reserve margin is 14%. As reserve margin increases, the CT carrying costs rise and the reliability energy costs made up of production costs above a CT, net imports above a CT, and expected unserved energy decrease. Between 14% and 16%, the flatness of the curve indicates that there is not a significant cost impact to being slightly above the minimum cost point. Since resource additions are too large to perfectly target a reserve margin, some years will inevitably result in reserve margins that are higher than the average economic optimum. The expected financial impact of these additions is not substantial, since the capacity above the weighted average target also brings some financial benefit. For example, the annual expected difference in cost between the 14% reserve margin and 16% reserve margin is only $9 million and can provide substantial risk benefit.

Figure ES2. Minimum Weighted Average Cost Reserve Margin

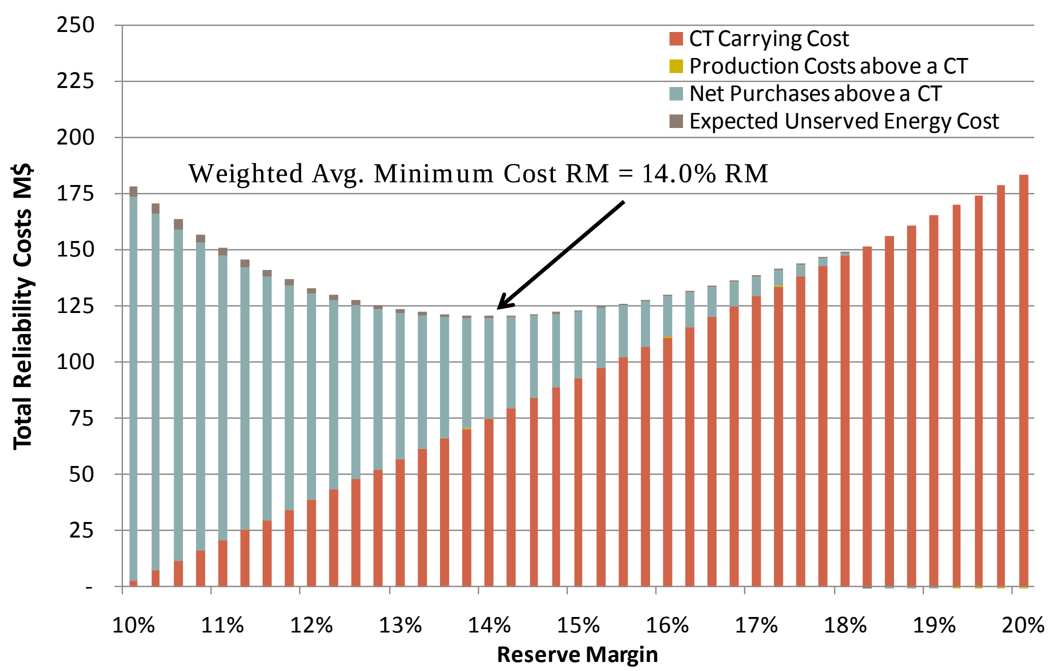


Figure ES3 demonstrates the distribution of reliability energy costs seen in Figure ES2 at each reserve margin level. It should be noted that even at the economic optimum reserve margin of 14% there is still potential for high reliability cost years due to abnormal weather, economic growth, or poor unit performance in the region as shown in the following figure. At a 14% reserve margin, there is a 5% chance that reliability energy costs could exceed $185 million in any given year and a 1% chance that it could exceed $303 million.

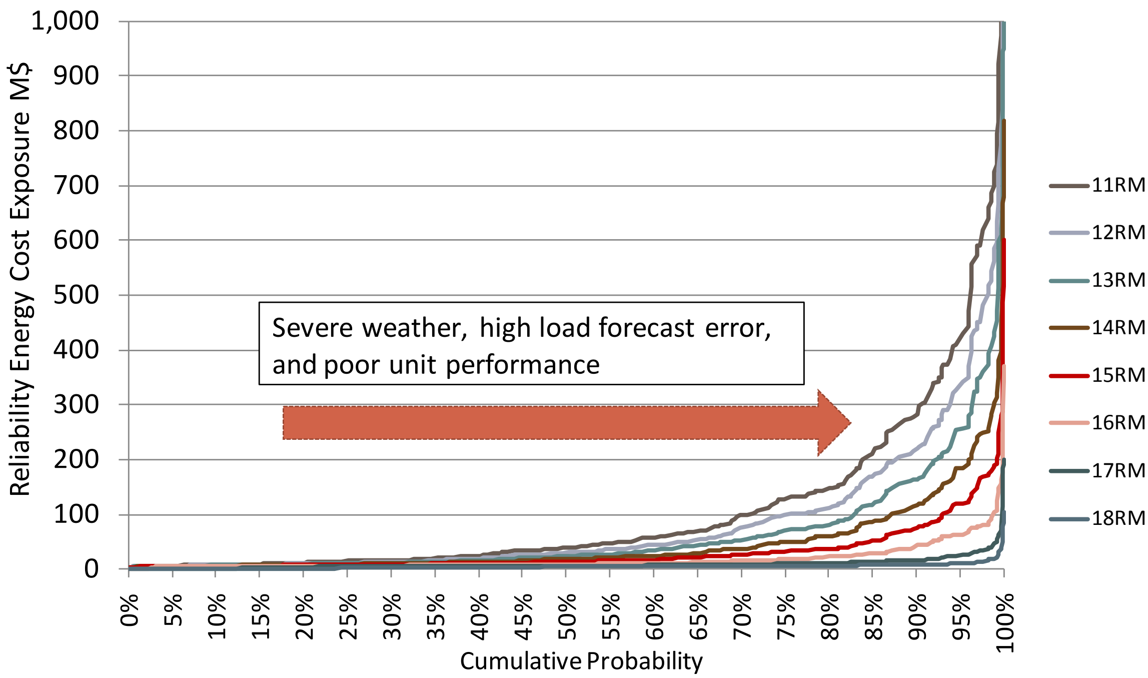
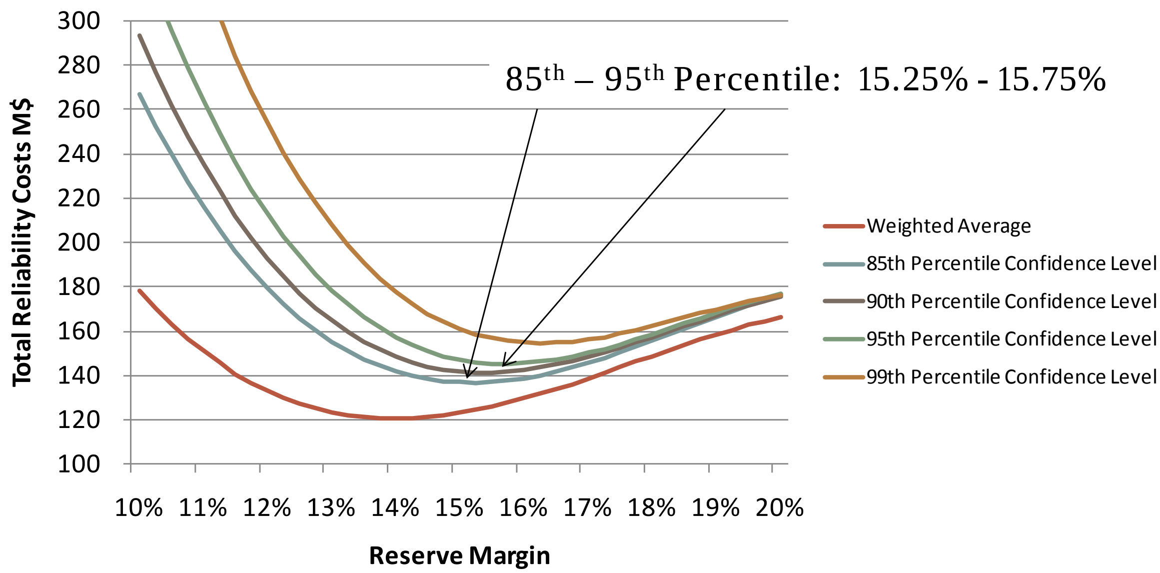
Figure ES3. Distribution of Reliability Energy Costs



Next we examined the optimal economic reserve margin recognizing the different risk profile of energy costs and capacity costs. By comparing capacity costs to reliability energy costs during years with extreme weather or poor unit performance as seen in Figure ES3, we assessed the tail benefit of additional capacity. The reliability energy costs seen in Figure ES3 were taken at different confidence levels (85%, 90%, 95%, and 99% probabilities) and added to the fixed capacity costs at each reserve margin to form the confidence level curves in Figure ES4. This assessment showed that in 10% of all scenarios, Duke

Energy would receive an economic benefit by adding efficient natural gas turbines up to a reserve margin of 15.50%. This is shown by the 90% confidence level curve in Figure ES4. As stated previously, when we review the weighted average curve in the same figure we can see that by adding capacity to achieve a 16% reserve margin versus a 14% reserve margin, average annual costs only increase by $9 million, but the additional capacity acts as an insurance product to customers. In fact, 10% of the time customers would see their cost exposure decrease by at least $70 million in any given year as seen in Figure ES3.

Figure ES4. Optimal Reserve Margins over a Range of Confidence Intervals



Recommendation

Astrape recommends that Duke set its absolute minimum reserve margin at the 14.5% LOLE target (LOLE = 0.1) and recommends a target of 15.50% based on the 90% confidence level economic target. Since capacity is added in large blocks to take advantage of economies of scale, the actual reserve margin will often be somewhat higher than the target threshold of 15.5%. As shown in the charts and data above, a reserve margin target in the range of 14.5% to 16% produces similar total customer costs whether at the low end or high end of the range. To accommodate large resource additions such as nuclear, coal, or even larger combined cycle resources, the reserve margin would likely rise above the top end of the reserve margin range. However, the additional production cost and economy of scale benefits provided by such resources would likely justify their addition. Therefore, the recommended target reserve margin of 15.50% with a range of 14.5% to 16% should not be considered absolute as all resource decisions should be made on a case-by-case basis.

I. List of figures

II. List of tables

III. Input Assumptions

A. Study Year

The selected study year is 2016. The year 2016 was chosen because it is three to four years into the future which is indicative of the amount of time needed to permit and construct a new generating facility. By looking three to four years out, this study reflects a longer term optimal reserve margin. Lower economic load forecast error as well as surrounding market conditions could potentially allow the company to carry slightly lower reserves in the short term.

Although 2016 was selected for the base case simulations, the SERVM simulation results should apply for the 3 to 5 year period following 2016 assuming that resource mixes and market structures do not change drastically over that term. To that end, several sensitivities were run to reflect changes in the market that could occur in this time period as well as a look at a 2023 Study Year.

B. Load Modeling

Table 1. 2016 Load Forecast

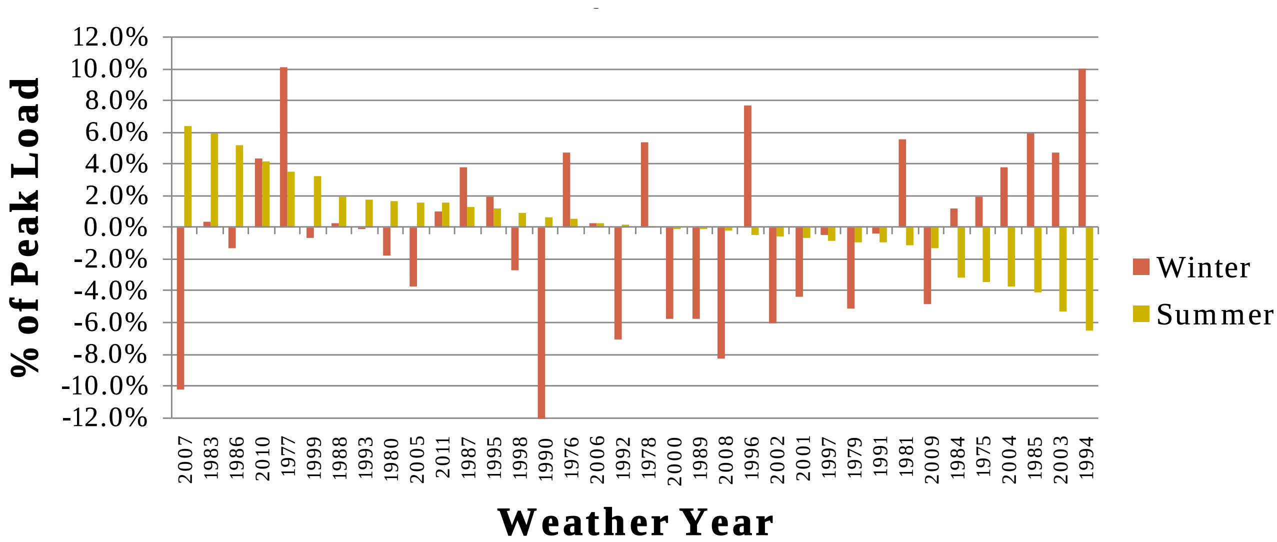
Month	Energy (MWh)	Peak Load (MW)
January	9,163,558	18,891
February	8,191,438	18,033
March	7,845,982	16,797
April	7,311,837	14,012
May	7,885,201	16,407
June	9,015,082	18,675
July	9,509,029	19,476
August	9,595,229	19,075
September	8,256,070	17,595
October	7,486,890	14,687
November	7,541,890	16,048
December	8,669,874	17,756

Table 1 displays the peak and energy forecasts for 2016 under normal weather conditions. The company is expected to have a winter peak of 18,891 MW and a summer peak of 19,476 MW. All values include the reduction for energy efficiency but exclude any other DSM reductions.

To model the effects of weather uncertainty, 37 historical weather years were developed to reflect the impact of weather on load. A neural network program was used to develop relationships between weather observations and load based on the last five years of historical weather and load. Different relationships were built for each month of the year using hourly temperature, time of day, day of week, 8 hour prior temperature, 24 hour prior temperature, 48 hour prior temperature, and heating and cooling degree hours.

These relationships were then applied to the last 37 years of weather to develop 37 load shapes for 2016. Equal probabilities were given to each of the 37 load shapes in the simulation. Figure 1 ranks all weather years by peak summer load for the system. In the most severe weather conditions, the summer peak can be approximately 6% higher than the peak under normal weather conditions and 10% for the winter. The reason for the larger variation in winter loads is the larger variation of temperature versus normal weather of 10 to 13 degrees whereas in the summer maximum variation versus normal weather is only 6 degrees.

Figure 1. Peak Load Variability Vs. Normal Weather



The difference in frequency of high load periods during winter versus summer can be seen in Figure 2. The duration of high load is far less in the winter causing the summer to have higher reliability risk. So despite higher variation in winter peak loads, sustained high loads in the summer cause the majority of reliability events.

Figure 2. Frequency of High Load Hours for Winter and Summer

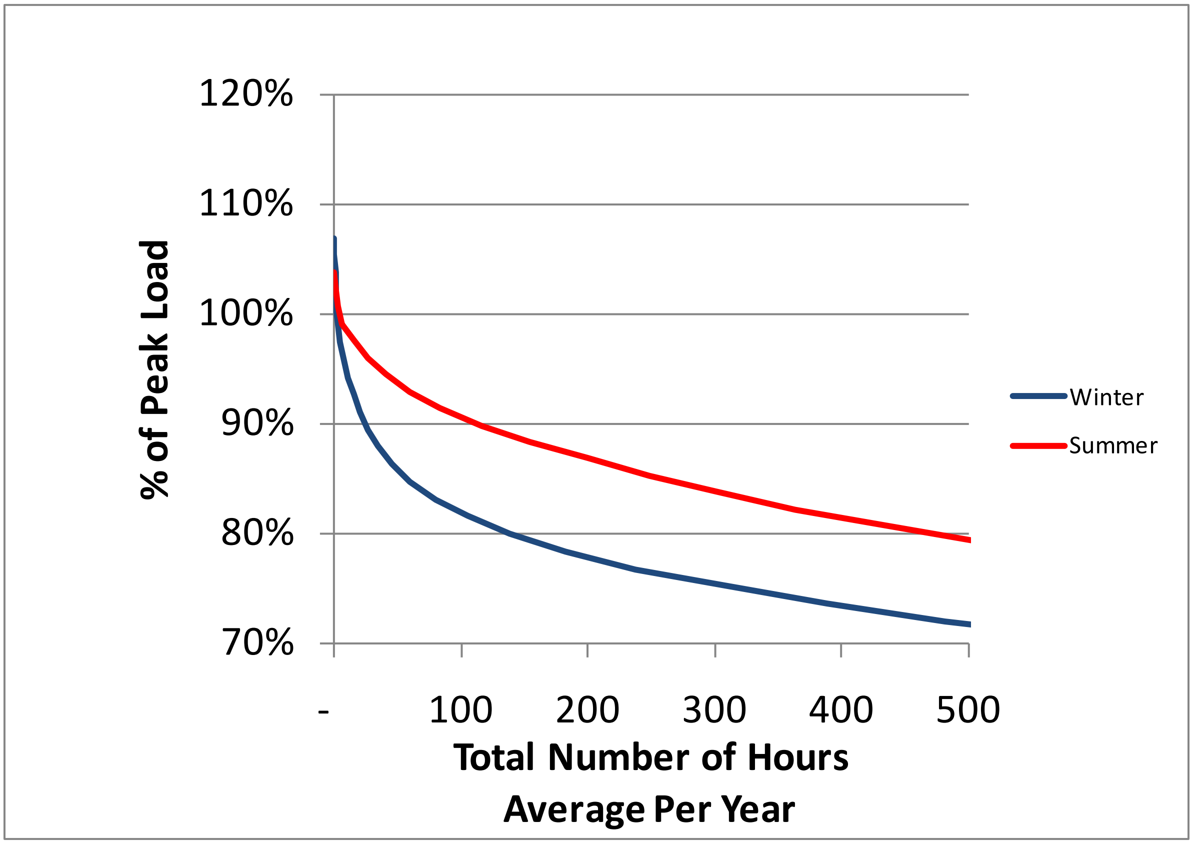


Table 2 summarizes the combined summer and winter peaks by weather year. The table shows that recent years including 2007 and 2010 were among the most severe summers.

Table 2. 2016 Peak Load Rankings for All Weather Years

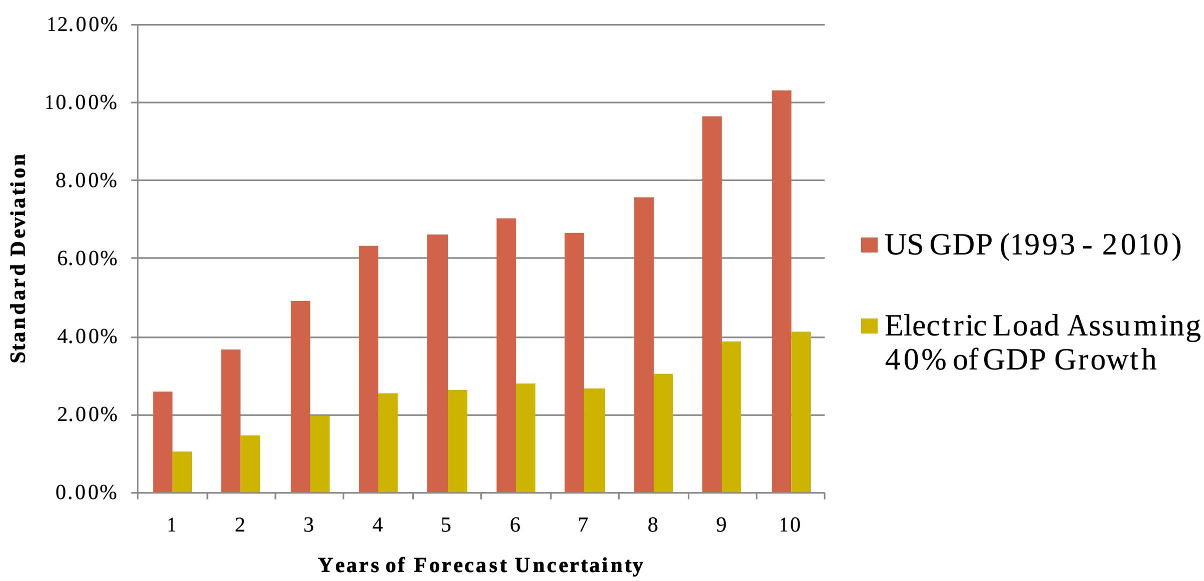
10	1988	101,879,158	0.8%

C. Load Forecast Error

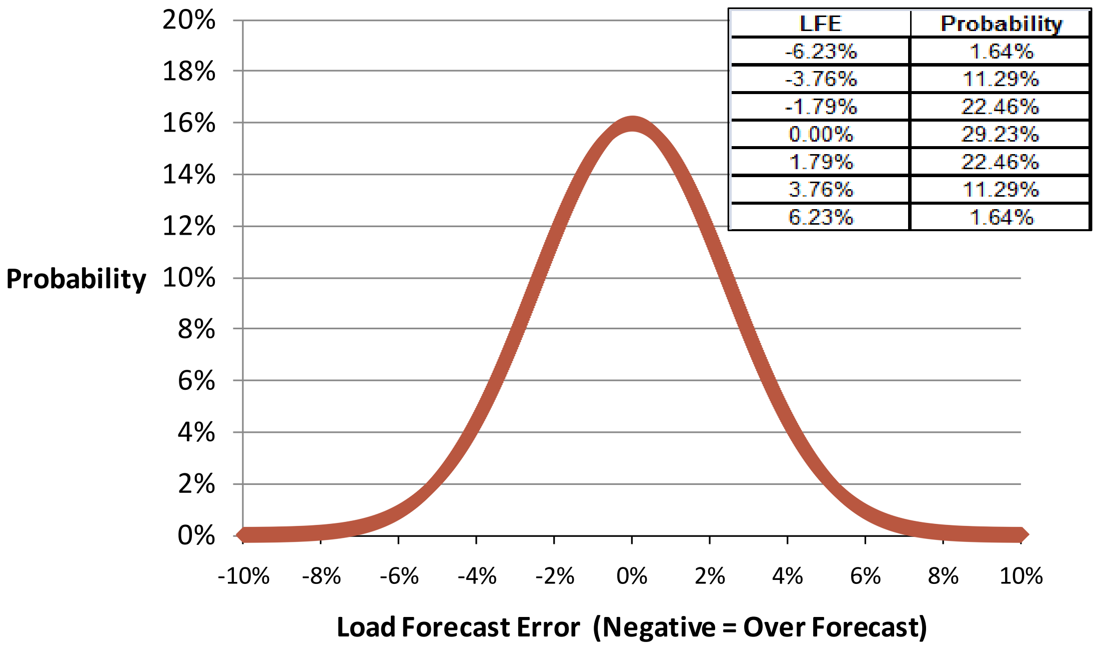
An analysis was performed using the historical Congressional Budget Office four year prior forecasts of GDP and comparing those forecasts to actual data from 1993 – 2010. Comparing how well GDP was predicted four years in advance provides insight into the economic uncertainty that should be applied to utility loads. The chart below shows the standard deviation of historical GDP forecast error for forecasting one to ten years in advance. As expected, the standard deviation of forecast error increases as the number of years increase. Based on discussions with Duke, electric load is assumed to grow at about 40% of GDP growth. Assuming four year forecast error, standard deviation for load forecast error uncertainty for utility load is 2.5% as shown in the following figure. If lead times for new generation changed substantially, then the standard deviation used to develop the economic load forecast error would need to be adjusted accordingly. However, it is unlikely that typical generation resources can be installed and brought in-service in less than three to four years given the time needed for environmental and regulatory approvals, construction, and startup testing.

Figure 3. Standard Deviation of GDP forecast error (1 to 10 Year Projections)



Astrape also performed a comparison of the company's historical four year prior forecasts to actual weather normalized load. Astrape observed that in recent years there was a tendency to over forecast given the economic downturns seen in the last decade. However, the standard deviation of load forecast error was 3.34%, which was in the range of the CBO study. The company and Astrape determined that using 2.5% was a reasonable value for the standard deviation and Astrape developed a normal distribution as shown in the following Figure 4. The continuous distribution was converted into a discrete distribution with the 7 points shown for use in determining discrete scenarios to be modeled. As an example of how to interpret the economic uncertainty data, there is a 1.64% chance that load will be 6.23% greater than forecasted.

Figure 4. Load Forecast Error



LFE	Probability
-6.23%	1.64%
-3.76%	11.29%
-1.79%	22.46%
0.00%	29.23%
1.79%	22.46%
3.76%	11.29%
6.23%	1.64%

SERVM utilized each of the 37 weather years and applied each of these seven load forecast error points to create 259 different load scenarios.

D. Resources

The resources and seasonal capacities for the 2016 study are shown in the following tables.

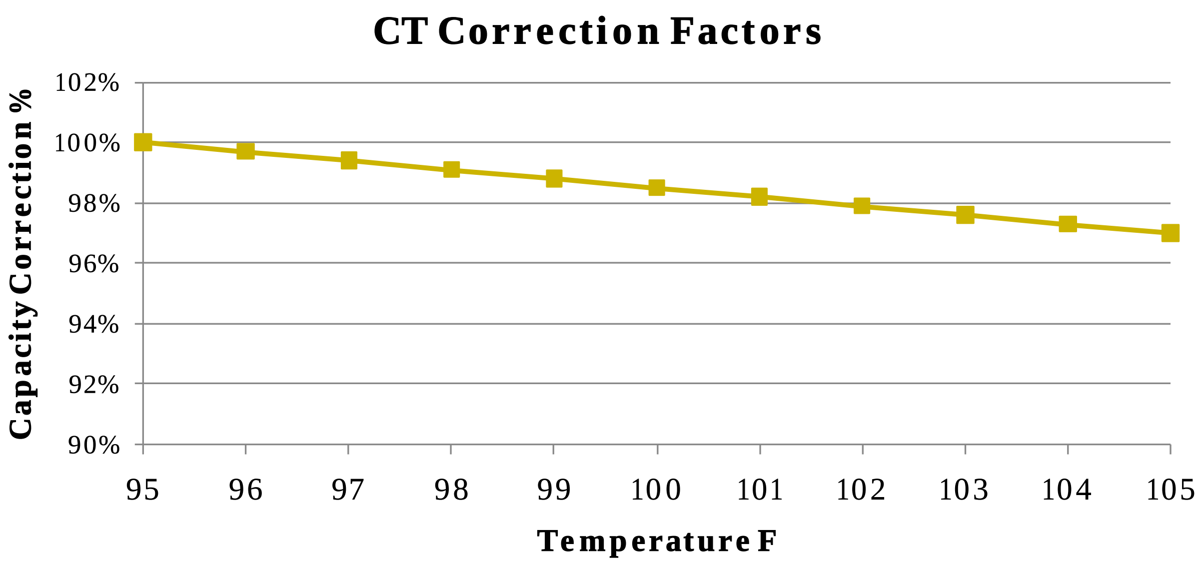
*IRP CT 2 is in service in June, 2016

All summer ratings in the previous tables are based on 95 degree F. On an hourly basis, SERVM can adjust the capacity of each resource based on the historical hourly temperature for the weather year being modeled. Because the maximum output of peaking units degrades as temperatures increase, the derating multipliers in Figure 5 were utilized to derate the units above 95 F. The multipliers were developed based on the Duke CT fleet which assumes a degradation of 0.3% of capacity per degree. This ensures correlation of capacity output with load since both are highly dependent on the hourly temperature.

Figure 5. Summer Rating Capacity Multipliers



The hydro portfolio is modeled in segments that include Run of River (ROR), Scheduled (Peak Shaving), and Emergency Capacity. The Run of River segment is dispatched as base load capacity providing its designated capacity every hour of the year. The scheduled hydro is used for shaving the daily peak load but also includes minimum flow requirements. If included, the emergency capacity is used only to prevent firm load shed and the model allows the emergency mode to "borrow" energy from the future dispatch of the scheduled hydro portion with the constraint that the energy amount is enough for only a few hours. Typically hydro resources are not able to be dispatched at their nameplate capacity during peak hours due to water constraints or river flow requirements as seen in 2008. By modeling the hydro resources in these three segments, the model captures the appropriate amount of capacity dispatched during peak periods. See the confidential Appendix for the details regarding hydro capacities.

Figure 6 shows the total breakdown of scheduled versus emergency hydro based on the last 37 years of weather. Out of the total 1,100 MW of capacity owned by the company, only 442 MW on average is dispatched during peak periods. During drought years, less than 390 MWs are dispatched on peak in specific months. For this reason, the use of emergency hydro was not included in the base case results due to recent experience, but a sensitivity was performed that included the additional emergency hydro capacity which could be utilized for a few hours per month.

Figure 6. Scheduled Capacity versus Emergency Capacity

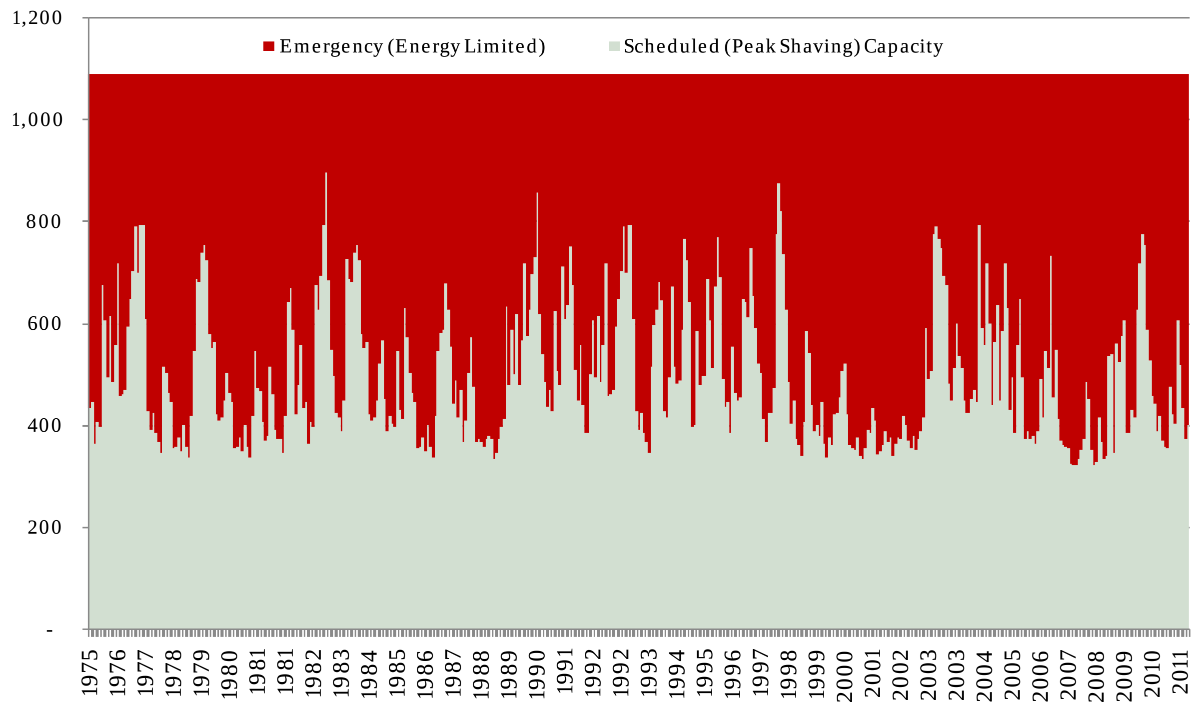


Figure 7 demonstrates the variation of hydro energy by weather year which is input into the model. The drought shown in 2001, 2007, and 2008 is captured in the reliability model.

Figure 7. Hydro Energy by Weather Year

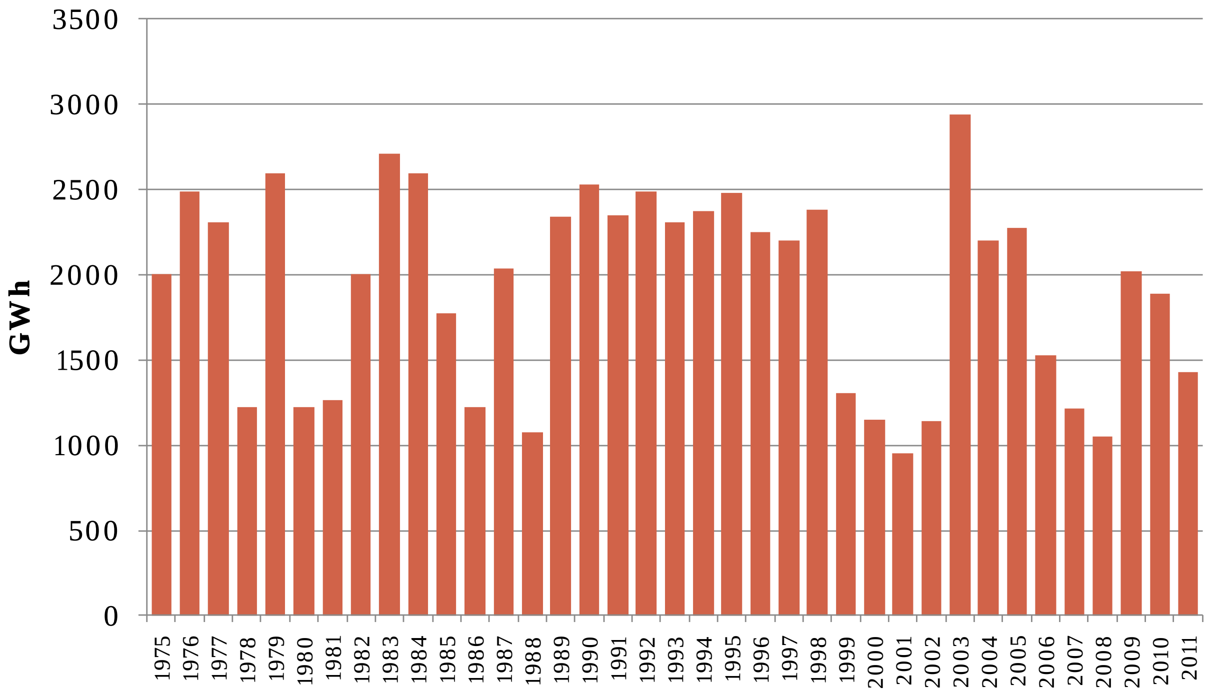

Figure 8 compares actual history of the dispatch level of the hydro resources for a 2008 and 2009 as a percentage of time versus how the model dispatches the resources. The figure demonstrates the drought conditions that were seen in 2008 and also shows that the model is capturing a realistic dispatch of the hydro resources.

Figure 8. Hydo Dispatch Calibration: Percent of Time above Capacity Threshold

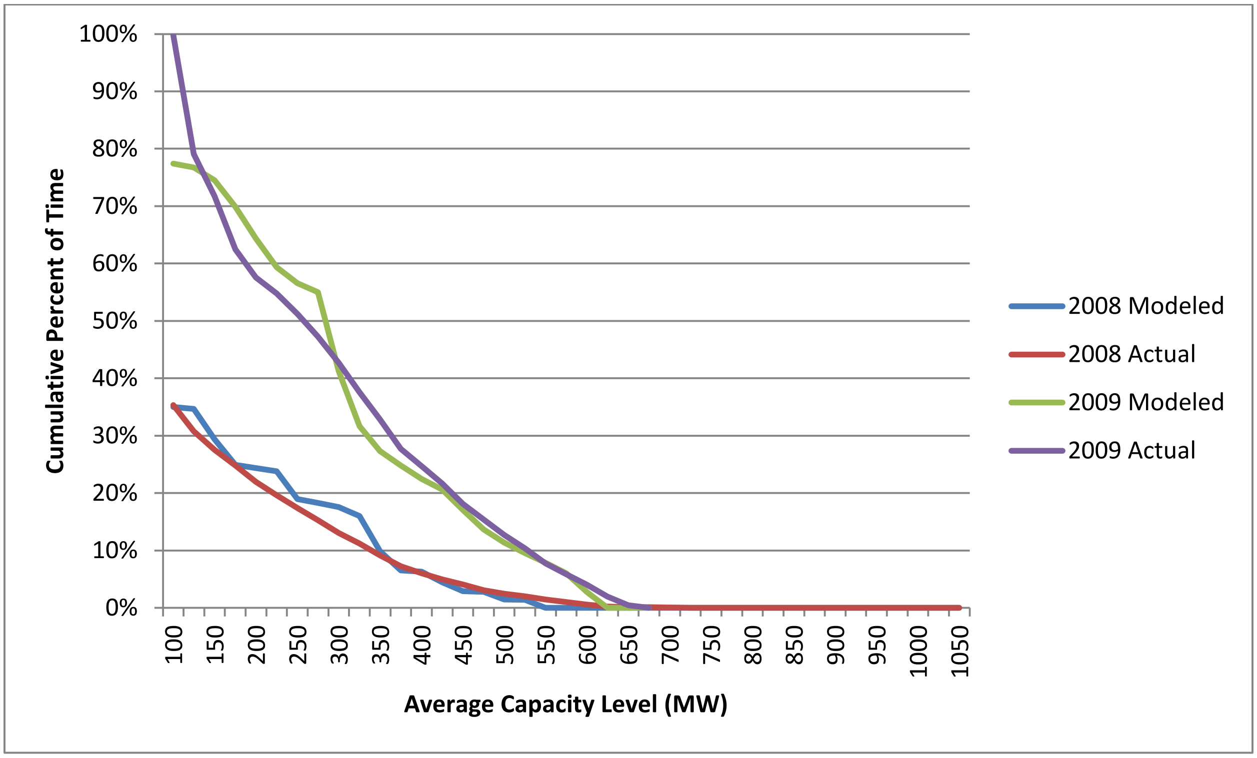

Table 7. Pump Storage Resources

Unit Name	January	July	Reservoir Capacity (MWh)	Reservoir Generating Hours
Bad Creek	1360	1360	33,030	24
Jocasse	780	780	57,540	74

Total	2140	2140

Pumping for pumped storage occurs anytime energy is available. During constrained periods, pumped storage resources are given dispatch priority to maintain a maximum level in the storage ponds. During less constrained periods, the dispatch order is switched so that the energy is used before CT's are dispatched. SERVM uses any excess capacity to fill up the ponds including economic purchases from the market. In actual practice, this process may be performed slightly differently to minimize production cost during off-peak periods. However, the model architecture is appropriate for reliability modeling, because it is always economic to build up the reservoirs of storage units with any generating asset available if that is what is required to have the units available to operate to avoid unserved energy.

Table 8. Renewable Resources

Unit Name	January	July
Solar – Nameplate Capacity	49	49
Wind – Nameplate Capacity	318	318
Landfill Gas	32	32
Poultry_PPA	14	14
Biomass_PPA	134	134
Totals	547	547

For reserve margin calculations, Solar capacity is given a 50% capacity credit and wind capacity is assumed to have a 15% capacity credit. For these resources, an 8760 hourly generation shape was used. The average summer and winter shapes are shown in Figure 9 and Figure 10. For each day, SERVM draws a daily shape from all the days in the month. Because historical data is unavailable, this random draw is used for all weather years.

Figure 9. Solar Profile

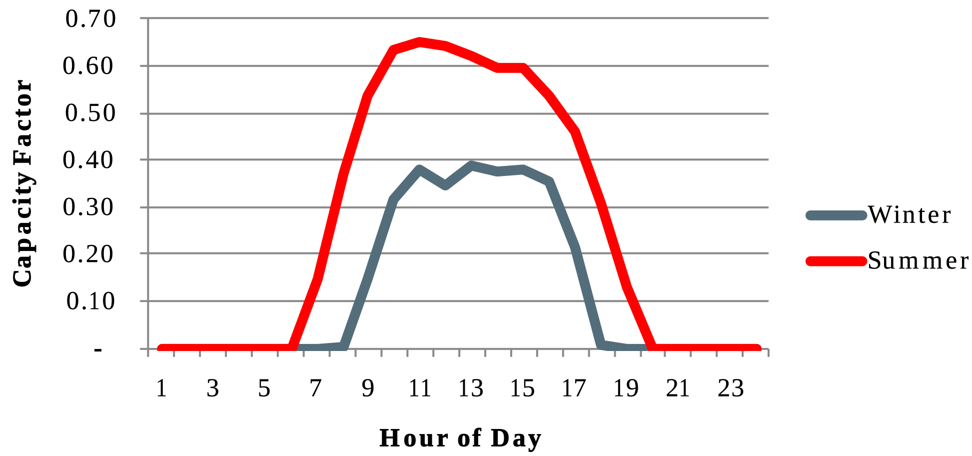

Figure 10. Wind Profile

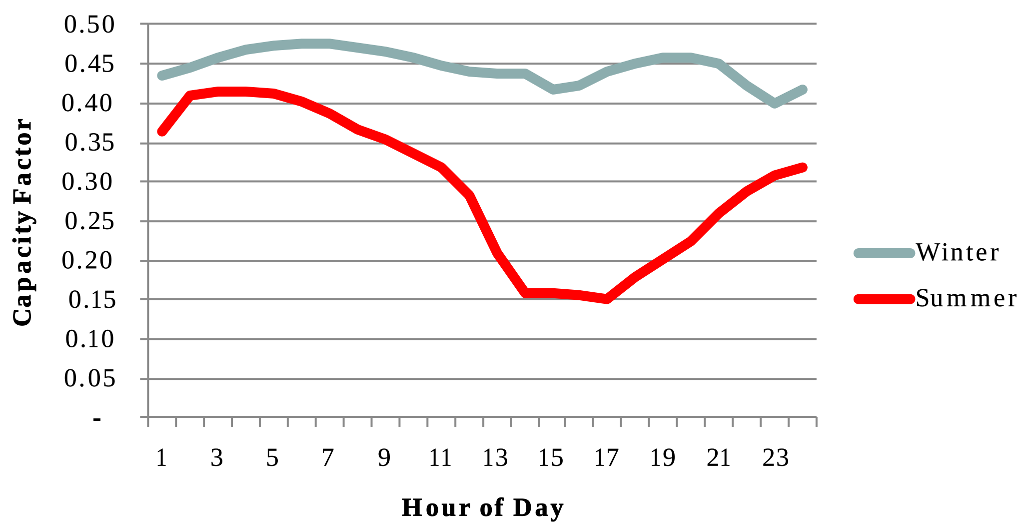


E. Unit Outage Data

Unlike typical production cost models, SERVM does not use an EFOR for each unit as an input. Instead, historical GADS data events are entered in for each unit and SERVM randomly draws from these events to simulate the unit outages. For this RM Study, 2007-2011 GADS events were entered into SERVM. The events are entered using the following variables:

Full Outage Modeling
Time-to-Repair Hours
Time-to-Fail Hours

Partial Outage Modeling
Partial Outage Time-to-Repair Hours
Partial Outage Derate Percentage
Partial Outage Time-to-Fail Hours

Maintenance Outages
Maintenance Outage Percentage - % of full outages that are maintenance outages. SERVM uses this percentage and allows units to remain online until the following weekend if they are needed in the short term.

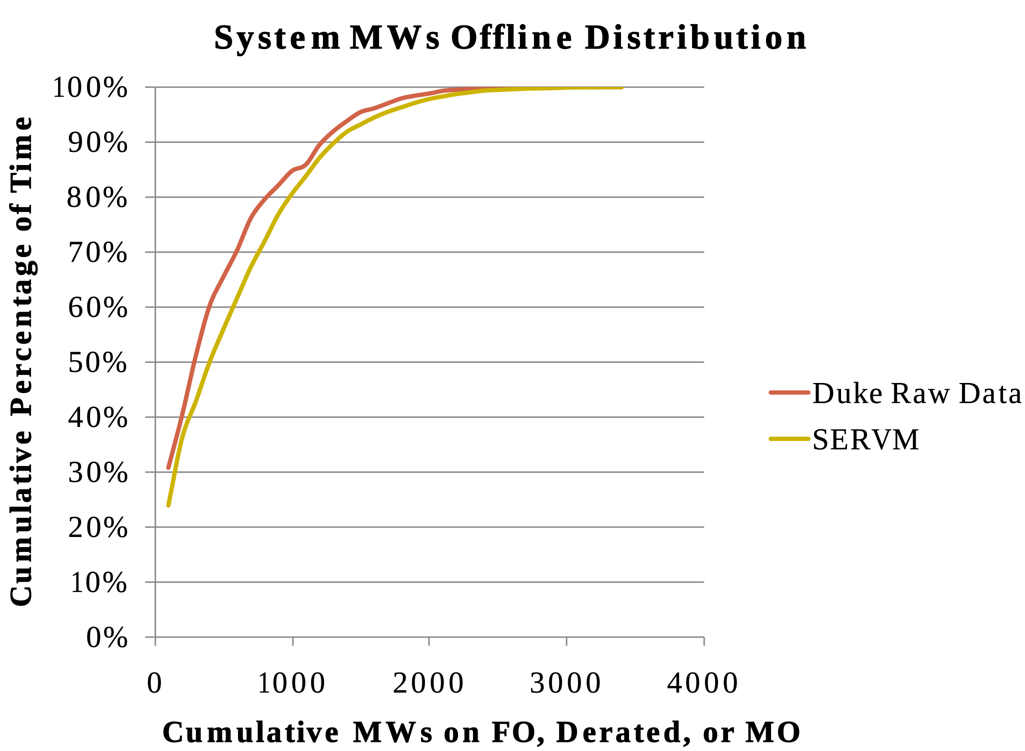
For example purposes, assume that from 2007 – 2011, Allen 1 had 15 full outage events and 30 partial outage events reported in the GADs data. The Time-to-Repair and Time-to-Fail between each event is calculated from the GADS data along with the other variables listed above. These multiple Time-to-Repair and Time-to-Fail distributions are used by SERVM. Because typically there is an improvement in EFOR across the summer, the data is typically broken up into seasons resulting in a set of Time-to-Repair and Time-to-Fail inputs for summer, off peak, and winter based on history. Assume Allen 1 is online in hour 1 of the simulation. SERVM will randomly draw a Time-to-Fail value from the distribution provided for both full outages and partial outages. The unit will run for that amount of time before failing. A partial outage will be triggered first if the selected Time-to-Fail value is lower than the selected full outage Time-to-Fail value. Next, the model will draw a Time-to-Repair value from the distribution and be on outage for that number of hours. When the repair is complete it will draw a new

Time-to-Fail value. The process repeats until the end of the iteration when it will begin again for the subsequent iteration. This more detailed modeling is important to capture the tails of the distribution that a simple convolution method would not capture.

Unit Outage Calibration

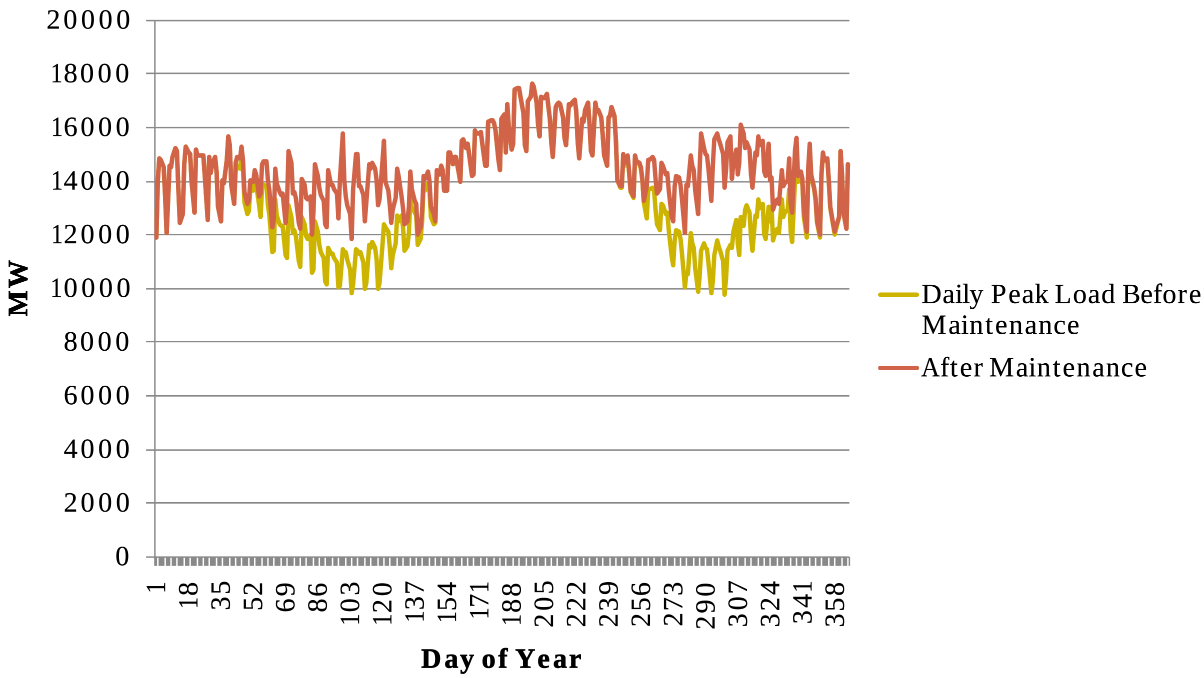
The critical aspect of unit performance modeling for a reliability study is the cumulative MW offline distribution. Most reliability problems are due to significant coincident outages. Figure 11 shows the distribution of outages for Duke Energy. The model has been calibrated to ensure this distribution is captured. Based on the data in the figure 10, the company may have 1,000 MW of capacity offline in 15% of all the hours. This equates to approximately 5% in reserve margin unavailable. System and individual outage rates are located in the confidential Appendix of this report. System and individual outage rates are located in the confidential Appendix of this report.

Figure 11. System Capacity Offline as a Percentage of Time



To capture the impact of planned maintenance, the 2016 maintenance schedule was modeled which removes capacity during the shoulder months of the year. Figure 12 shows that when planned maintenance is assumed in the shoulder months that the resulting load level between winter and shoulder periods is relatively flat.

Figure 12. Daily Peak Load Plus Planned Maintenance Requirement



F. Demand Response

A total of 987 MWs of demand response were modeled in the simulation. Energy efficiency (EE) was directly removed from load in the simulation while the resources in Table 9 were modeled as resources to be called upon given a reliability event. SERVM takes into account the constraints on demand response and dispatches accordingly. These constraints include a maximum number of hours per year, hours per day, days per week, and shadow dispatch price for the resources to be called.

Table 9. Demand Response Summary

Unit Name	January Capacity	July Capacity	Hours Per Year Limit	Hours Per Day Limit	Days Per Week Limit

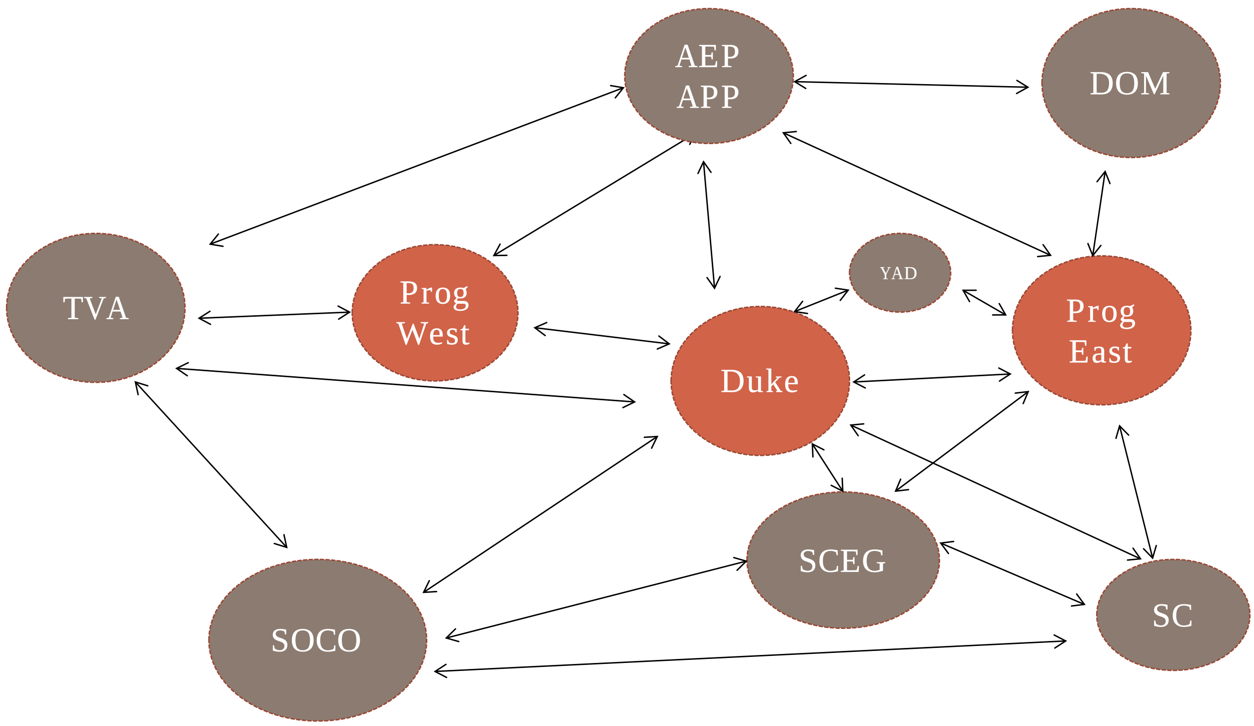
G. Multi Area Modeling

The surrounding market must play a significant role in resource adequacy even for a utility the size of Duke Energy Carolinas. If several large generators are offline due to outage during peak season, it is likely that the company would depend on market purchases from surrounding regions.

The market representation used in SERVM was developed through consultation with Duke Energy Staff, EIA forms, Company Integrated Resource Plans (IRP), and reviews of NERC resource adequacy assessments. The base case level of reserves for neighbors is based on target reserve margins for surrounding neighbors. Using this methodology ensures that the company is not leaning on an external market more than is reasonable. Figure 13 shows the topology used for the region.

Figure 13. Regional Topology



Each neighbor's hourly loadshape was modeled based on historical hourly temperature data similarly to the Duke load. By using hourly weather, load diversity was captured for each neighboring area. Diversity of peak load is important to understand especially when examining physical reliability metric results. Table 10 shows the average diversity for summer months across all 37 years for each area. These values represent the percentage reduction from peak load that the neighbor is on average experiencing when Duke is experiencing its peak load. To ensure that Duke was not overstating the expectation of weather diversity and therefore available capacity from neighbors, Astrape believed it was prudent to cap the weather diversity in any given peak hour at 3%. A sensitivity assuming no weather diversity was simulated to understand the impact that weather diversity has on lowering the target reserve margin.

Table 10. Neighbor Diversity Factors

	Summer Diversity
SOCO	1.5%
AEP	1.7%
Dominion	1.9%
TVA	1.5%
SCEG	1.3%
Santee Cooper	1.3%
Progress East	1.2%
Progress West	3.3%

Table 11 displays a capacity and load summary of each of the neighbors including its current target reserve margin. The reserve margin calculations in this table assume that the interruptible capacity is included as a resource. While it is recognized that the region currently contains more capacity than these targets, it is not prudent to expect these additional reserves to be available long term. Outage rates for neighboring units were developed using existing Progress and Duke resources sorted by unit type and capacity size. Hydro resources reflect similar dispatch to the Progress and Duke hydro portfolios.

Table 11. Neighbor Capacity, Load, and Target Reserve Margin

	Progress	Southern Company	Santee Cooper	SCE&G	TVA	AEP_APP	DOM	Yadkin
Nuclear	3,563	6,895	318	2,066	7,832	0	3,501

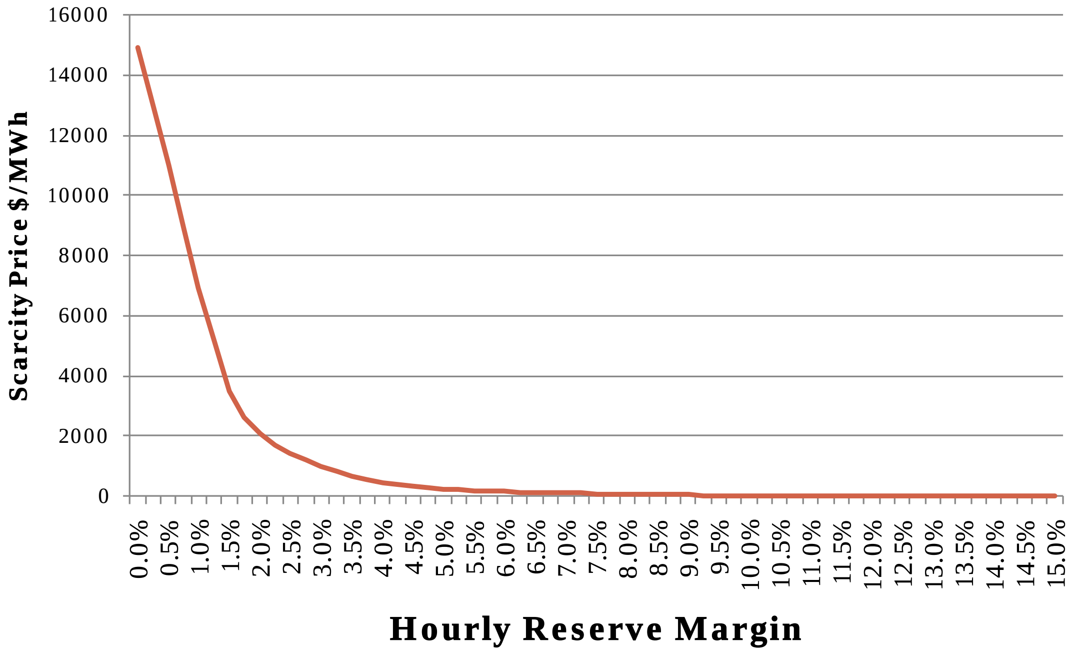
Summer Reserve Margin	15.4%	15.9%	15.5%	16.3%	15.4%	16.1%	15.2%	

*includes renewable capacity

The costs of market purchases were calibrated using Duke Energy historical purchases and other market pricing data from the southeast region. As shown in Figure 14, scarcity pricing is based on the shortage in the specific region. As the excess capacity approaches zero, the price of capacity approaches the cost of unserved energy. Such an event is rare but can occur as a function of severe weather, poor unit performance, and significant load forecast error.

Figure 14. Scarcity Pricing Model



Available Transmission Capacity and TRM

The import capability is made up of Available Transmission Capability (ATC) and Transmission Reliability Margin (TRM). ATC is the non firm hourly transmission expected to be available in the market place while TRM is the portion of the transmission system that is held back for reliability needs. TRM is a fixed number while ATC is highly volatile. Due to its highly volatile nature, ATC is represented as a distribution to capture hours when there is little capacity to hours when there is abundance. The distributions used in SERVM are based on historical hours in 2011 during peak periods. It should be noted that these limits do not represent the amount of generation available from neighbors but only serve as the import constraint. Given these constraints, it is expected that the limiting factor will be generation availability from neighbors rather than transmission. However, transmission capability will be a critical sensitivity in the final analysis. See the appendix for details regarding the values used for ATC and TRM.

H. Carrying Cost of Capacity

The cost of carrying incremental reserves was based on the capital cost, fixed O&M, and estimated transmission upgrades of four Advanced CTs with a total summer rating of 740 MW. The cost assumptions were based on estimates provided by Duke Energy. The appendix displays the characteristics and costs of the four CT site used to develop the capacity costs and the avoided and levelized costs by year.

I. Operating Reserve Requirements

Duke provides 500 MW of spinning reserves and 600 MWs of total operating reserves which was implemented into the model.

J. Cost of Unserved Energy

Unserved energy costs were derived based on information from national studies completed for the Department of Energy in 2003 and 2009. The national studies were compilations of other surveys performed by utilities over the last two decades. The national study split the customer classes into residential, small commercial and industrial, and large commercial and industrial. The 2009 study shows higher costs for commercial and industrial consumers compared to 2003. We expect that the costs of outages have risen rapidly in recent history for commercial and industrial customers due to the impact of technology; however both Duke and Astrape questioned the $92.16/kWh values shown in the 2009 Study for Small C&I. Given the magnitude of the values seen in both studies, Astrape and Duke determined that $15,000/MWh was a reasonable base case assumption Due to the infrequent nature of unserved energy; the sensitivity results demonstrate that this assumption is not the main driver of the results.

Table 12. Unserved Energy Costs

	Class Breakdown %	2003 DOE Study 2003$/kWh	2009 DOE Study 2008$/kWh	2003 DOE Study 2016$/kWh	2009 DOE Study 2016$/kWh
Residential	35%	1.15	1.10	1.45	1.27
Small C&I	37%	26.00	79.90	32.79	92.16
Large C&I	28%	15.00	23.80	18.92	27.45
Weighted Average $/kWh				17.93	42.23
Average of Studies $/kWh				30.08	

V. Simulation Methodology

Since most reliability events are high impact, low probability events, a large number of scenarios must be considered. Deterministic selection of extreme events will not give an accurate representation of the operation of any system during such an event, nor would it be possible to estimate a distribution of when such events could occur. For Duke Energy, SERVM utilized 37 years of historical weather and load shapes, 7 points of economic load growth forecast error, and 400 iterations of unit outage draws to represent the full distribution of realistic scenarios. The number of yearly simulation cases equals 37 weather years * 7 load forecast errors * 10 reserve margin levels = 2590 total cases. For each of these cases, 400 iterations of unit outage draws are performed which means over one million yearly simulations were completed for the analysis. From this analysis, expected reliability costs can be calculated and compared to the cost of adding additional reserves.

A. Case Probabilities

An example of probabilities given for each case is shown in Table 13. It is assumed that each weather year is given equal probability and each weather year is multiplied by the probability of each load forecast error point to calculate the case probability.

Table 13. Case Probability Example

Weather Year	Weather Year Probabilitiy	Load Forecast Error	Load Forecast Error Probability	Total Case Probability (Weather Yr Prob x LFE Prob)
1975	2.70%	-6.23%	1.64%	0.0443%
1975	2.70%	-3.76%	11.29%	0.3051%
1975	2.70%	-1.79%	22.46%	0.6070%
1975	2.70%	0.00%	29.23%	0.7900%
1975	2.70%	1.79%	22.46%	0.6070%
1975	2.70%	3.76%	11.29%	0.3051%
1975	2.70%	6.23%	1.64%	0.0443%
1976	2.70%	-6.23%	1.64%	0.0443%
1976	2.70%	-3.76%	11.29%	0.3051%
1976	2.70%	-1.79%	22.46%	0.6070%
1976	2.70%	0.00%	29.23%	0.7900%
1976	2.70%	1.79%	22.46%	0.6070%
1976	2.70%	3.76%	11.29%	0.3051%
1976	2.70%	6.23%	1.64%	0.0443%

For this study, reliability costs are defined as the following:

1) Carrying Cost of Reserves + Production costs above that of a CT + Imports above the cost of a CT + Expected Unserved Energy Costs - Sales above that of a CT

These components are calculated for each of the above cases and weighted based on probability to calculate an expected reliability cost for the year.

B. Reserve Margin and Capacity Margin Definition

For this study, reserve margin is defined as the following:

- Reserve Margin = (Resources – Demand) / Demand
    - Demand is the Average Summer System Peak Load and has not been reduced by Demand Response
    - Resources are defined based on summer ratings and include Demand Response
    - The solar capacity within the study was given a 50% capacity credit while wind was given a 15% capacity credit (consistent with the 2011 IRP)

VI. Base Case Results

A. Physical Reliability Results

From a physical reliability standpoint, Figure 15 shows LOLE in events per year and LOLH in hours per year for the base case. The one day in 10 year standard (LOLE = 0.1 events per year) falls at a 14.5% summer reserve margin and the LOLH is approximately 0.30 hours per year for that level of reserves. Figure 16 displays expected unserved energy (EUE) at varying levels of reserves. At the 14.5% reserve margin level, EUE is 170 MWh. As demonstrated in the additional sensitivities, physical reliability metrics are sensitive to input assumptions such as weather diversity, transmission availability, neighbor reserve levels, and emergency hydro assumptions.

Figure 15. Base Case LOLE and LOLH

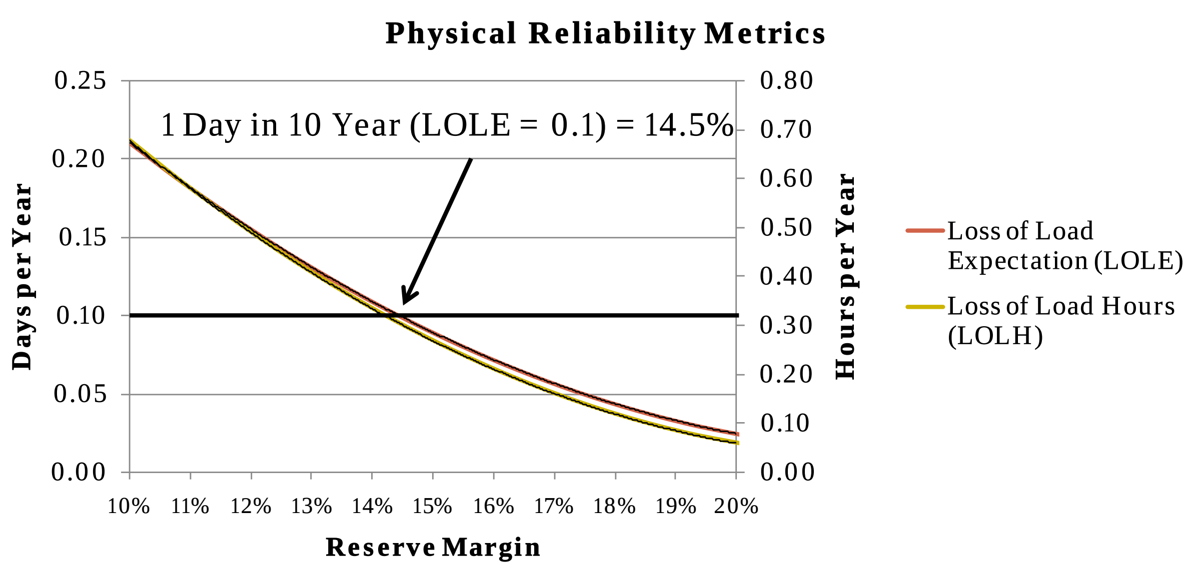


Figure 16. EUE

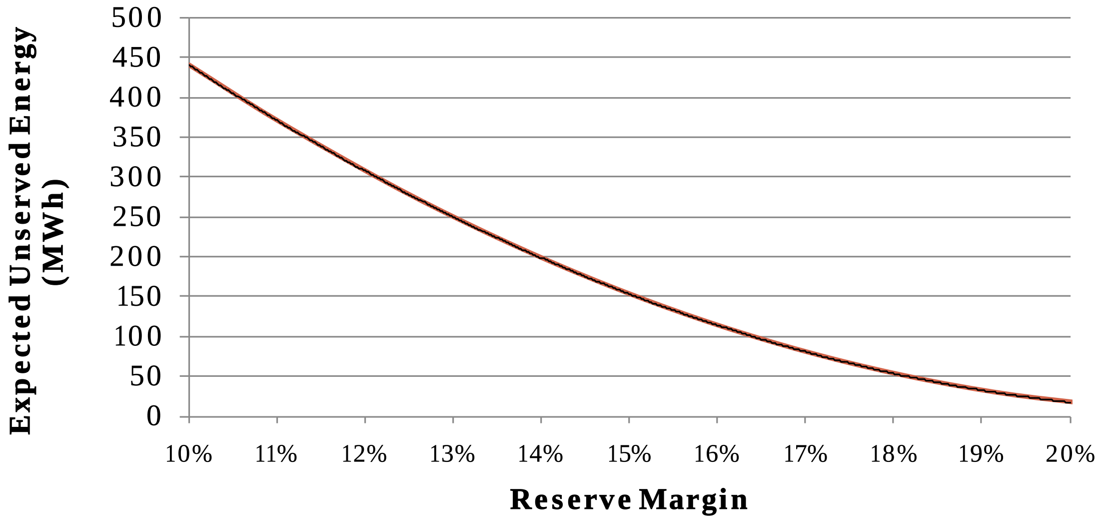
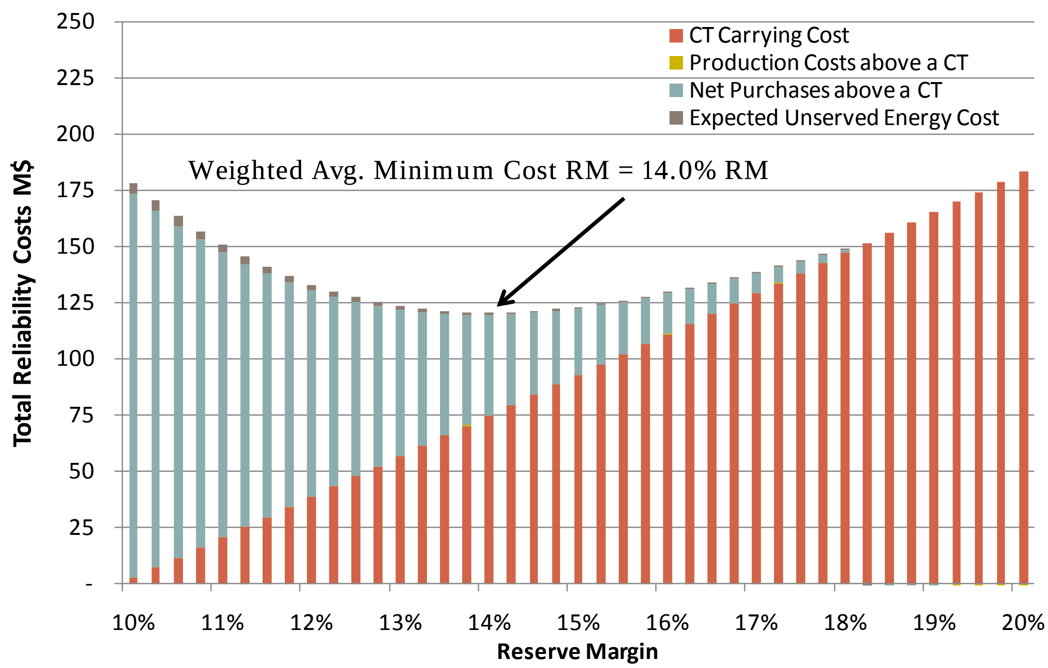


B. Economic Results

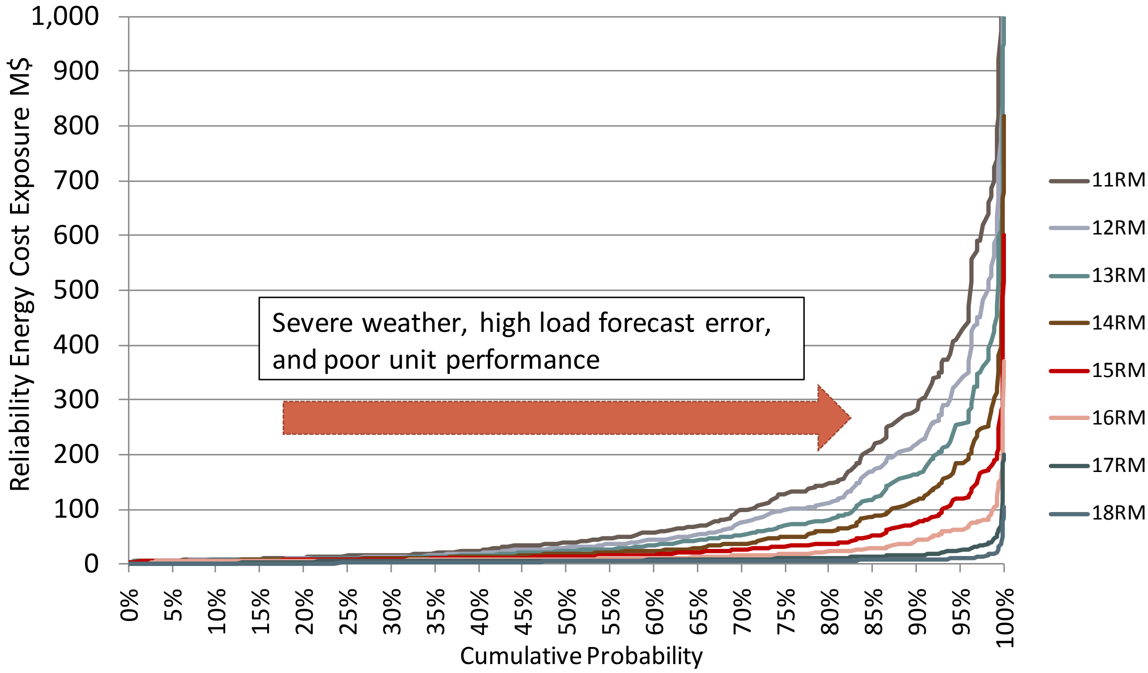
As previously discussed, physical reliability metrics only provide guidance for meeting a few peak load hours over a multi-year study period, and are therefore difficult to calibrate. To supplement the information provided by the base case LOLE analysis, economic reliability metrics were taken into consideration. Economic reliability costs include all costs from the next highest cost resource after a marginal CT all the way to the economic impact of shedding firm load. Since additional capacity will have some benefits in every year, this type of analysis is easily calibrated to actual practice and then allows accurate extrapolation to extreme scenarios. The base case economic results are shown in Figure 17. Based on these results, the long-term minimum cost reserve margin based on the weighted average of all results is 14%. As reserve margin increases, reliability energy costs (Production cost above a CT, net reliability imports above a CT, and cost of unserved energy) decrease while CT carrying cost increases. The flatness of the curve between 14% and 16% should be noted. Since resource additions are too large to perfectly target a reserve margin, some years will inevitably result in reserve margins that are higher than the average economic optimum. The expected financial impact of these additions to the total system cost is not substantial, since the capacity above the weighted average target also brings some financial benefit. For example, the annual expected difference in cost between the 14% reserve margin and 16% reserve margin is only $9 million and the higher level of reserves may provide risk benefits.

Figure 17. Base Case Weighted Average Economic Reserve Margin



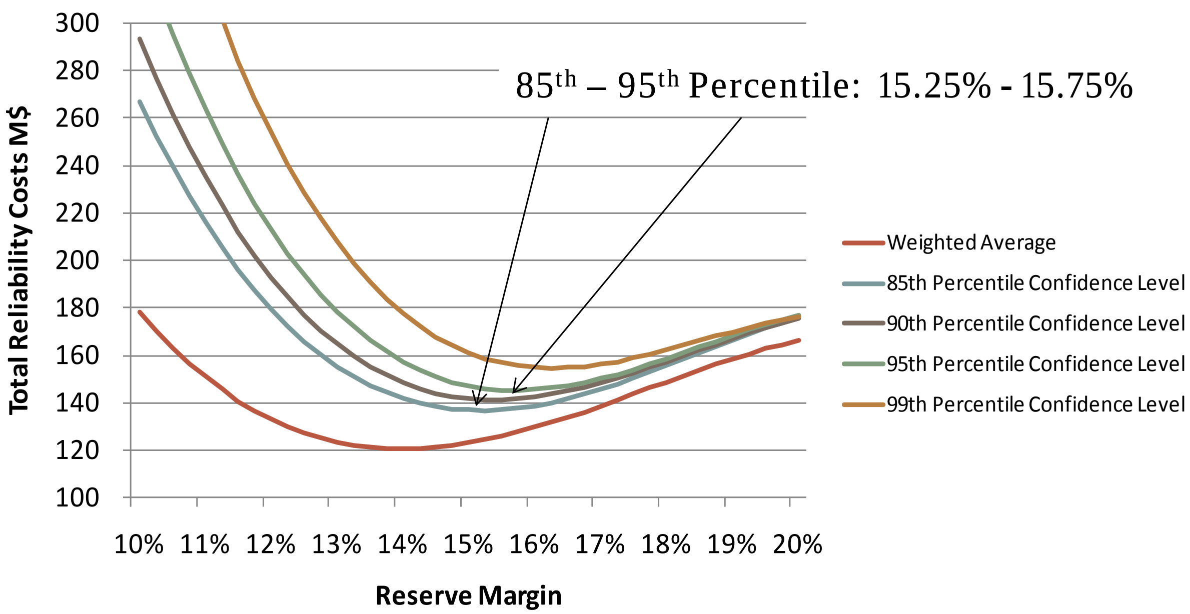
The previous figure represents the weighted average cost exposure and does not illustrate the high cost outcomes that can occur at each reserve margin level. While CT costs are mostly fixed, reliability energy costs are volatile dependent on the weather, load forecast error, or unit performance in a given year, so other confidence levels should be reviewed. While over a 30 year period this may be the optimal reserve margin, any single year can have significant risk at a 14% reserve margin level. Figure 18 shows the reliability energy costs on a probability weighted basis. At a 14% reserve margin, there is a 5% chance that reliability energy costs could exceed $185 million in any given year and a 1% chance that it could exceed $303 million.

Figure 18. Base Case Reliability Cost Exposure Distribution



Next we examined the optimal economic reserve margin recognizing the different risk profile of energy costs and capacity costs. By comparing capacity costs to reliability energy costs during years with extreme weather or poor unit performance as seen in Figure 18, we assessed the tail benefit of additional capacity. The reliability energy costs seen in Figure 18 were taken at different confidence levels (85%, 90%, 95%, and 99% probabilities) and added to the fixed capacity costs at each reserve margin to form the confidence level curves in Figure 19. This assessment showed that in 10% of all scenarios, Duke Energy would receive an economic benefit by adding efficient natural gas turbines up to a reserve margin of 15.50%. This is shown by the 90% confidence level (probability) curve in Figure 19. As we review the weighted average curve in the same figure we can see that by adding capacity to achieve a 16% reserve margin versus a 14% reserve margin, average annual costs only increase by $9 million, but the additional capacity acts as an insurance product to customers. In fact, 10% of the time customers would see their cost exposure decrease by at least $70 million as seen in Figure 18.

Figure 19. Risk Adjusted Reserve Margins



VII. Sensitivity Analysis

The following sensitivities were performed on the base case to only understand the movement in target reserve margins for both physical and economic metrics.

- Include Emergency Hydro: Allows the full nameplate capacity of the hydro fleet to be dispatched during peak periods.
- No Weather Diversity: All neighbors were given the same load shape as Duke to force all neighbors to peak at the same time.
- 50% ATC: The distributions of ATC were reduced by 50% to understand how transmission was impacting the base case results.
- Island Case: Duke is modeled as an island with no outside assistance.
- +2% Neighbor RM Level: The capacity of all neighbors was increased by a 2% reserve margin.
- +50% System EFOR: The EFOR for all Duke resources was increased by 50%.

- Marginal Resource Cost: +/- 25%: The capacity costs for the marginal resource was varied by +/-25%.
- EUE Cost: The cost of unserved energy was varied from $5,000/MWh to $25,000/MWh.
- 2023 Study Year: The study year was moved from 2016 to 2023. Load growth and generation expansion were included for each region and escalation in all economic factors such as the cost of EUE, scarcity pricing, and fuel prices was included for this sensitivity.

Table 14 shows the results of each sensitivity simulated. It is seen that the 0.1 LOLE reserve margin is more sensitive to key assumptions than the weighted average economic case. As discussed previously, this occurs because LOLE is impacted by only a few hours while economics looks at the broader economic impact of all costs above the costs of a CT.

The results show that LOLE is very sensitive to emergency hydro assumptions, weather diversity, and neighbor assistance while the economic results were more stable. Allowing the emergency hydro to be available during all peak periods decreases the LOLE target RM by 3.25% to 11.25% while the economic results were unchanged. Excluding weather diversity shifted the LOLE target up by 3.75 percentage points and the economic target up by 1 percentage point. Dividing the ATC distributions in half had a 1 percentage point impact on the LOLE target and a 2.5 percentage impact on economic results. The ATC sensitivity impacted transmission availability for every hour and so impacted the economic results more than LOLE. However, this sensitivity still indicates that even if substantial changes were to occur to the transmission system (loss of 50% of hourly available transmission capacity), target reserve margins would not need to shift dramatically. Increasing neighbor reserve levels by 2% shifted the LOLE target down by 3.75 percentage points and the economic target down by 0.75 of a percentage point. The island sensitivity should be seen purely as an academic exercise demonstrating the level of reserves the company would carry if it had no outside assistance. If Duke was a stand- alone utility, then it would need to carry reserves of 23.25%. In studying the year 2023, the target only changed slightly. It is expected that a long term reserve margin study should evaluate an optimal target three to five years in the future and therefore 2023 would need to be reviewed again in the 2018 to 2020 time frame.

Regarding the Economic Sensitivities, the cost of unserved energy had little impact on the overall results since firm load shed events are so rare, however, the cost assumed for the marginal CT resource moved the economic reserve margin by approximately +/- .75 of a percentage point. As the marginal resource cost increases, the economic target decreases.

Table 14. Sensitivities

	Physical	Economics	
	LOLE: 1 in 10 Standard Target RM	Weighted Average Target RM	90% Target RM
Base Case	14.50%	14.00%	15.50%
Include Emergency Hydro	11.25%	14.00%	15.50%
No Weather Diversity	18.25%	15.00%	16.75%
50% ATC	15.50%	16.50%	17.50%
Island Case	23.25%		
+2% Neighbor RM	10.75%	13.25%	15.25%
+50% System EFOR	16.75%	16.25%	17.50%
2023 Study Year	14.25%	14.00%	15.75%
EUE Cost: $25,000/MWh		14.00%	15.75%
EUE Cost: $5,000/MWh		13.75%	15.25%
Marginal Resource Cost: +25%		13.25%	14.75%
Marginal Resource Cost: -25%		14.75%	16.00%

VIII. Conclusions/Recommendations

Astrape recommends that Duke set its absolute minimum reserve margin at the 14.5% LOLE target (LOLE = 0.1) and recommends a target of 15.50% based on the 90% confidence level economic target. Since capacity is added in large blocks to take advantage of economies of scale, the actual reserve margin will often be somewhat higher than the target of 15.5%. As shown in the charts and data above, a reserve margin target in the range of 14.5% to 16% produces similar total customer costs whether at the low end or high end of the range. To accommodate large resource additions such as nuclear, coal, or even larger combined cycle resources, the reserve margin would likely rise above the top end of the reserve margin range. However, the additional production cost and economy of scale benefits provided by such resources would likely justify their addition. Therefore, the recommended target reserve margin of 15.50% with a range of 14.5% to 16% should not be considered absolute as all resource decisions should be made on a case-by-case basis.

The results should be reviewed periodically as there are shifts in generation mix, DSM, intermittent resource penetration, or load shape that could impact results. Provided that the results are greatly impacted by regional reserve margins, it is also recommended that Duke keep a close eye on the surrounding market. Short term capacity decisions should also be reviewed on a case-by-case basis. Since physical capacity changes can rarely be implemented inside a 3-year window, the cost of any procurement should be weighed against the distribution of reliability events and the distribution of reliability costs associated with not purchasing the capacity. Even in cases when Duke is below its minimum target reserve margin, economic and physical reliability metrics may suggest not procuring additional capacity. Or an analysis may suggest purchasing more capacity than is needed to achieve the minimum target.

FPL

The Need for a 3rd Reliability Criterion for FPL: a Generation-Only Reserve Margin (GRM) Criterion

Bob Barrett
VP Finance
February 28, 2014

A Note Regarding this New Presentation

- **This presentation first addresses 4 "carry over" topics from the Dec. 6th meeting:**
  1. What does a projected LOLP value really mean?
  2. LM customer "fatigue" benchmarking results.
  3. Benefits of generation reserves during pre-hurricane periods.
  4. Emergency declarations and regulatory scrutiny.

- **The presentation then discusses FPL's need for a new reliability criterion from 3 perspectives:**
  1. A "looking back" analysis of the Winter peak day of 2010 and what might have occurred if FPL had entered that January having a Summer GRM of 10% or 5%*
  2. A "looking forward" analysis using the year 2021
  3. Why 10% is a reasonable value for the new GRM criterion

- **The presentation concludes with a summary of "next steps"**

* Unless otherwise noted, all GRM values are Summer GRM values (because the Summer GRM values will have the most impact on resource planning)

FPL.

Executive Summary

- A generation-only reserve margin (GRM) reliability criterion is desirable from an operational perspective for several reasons:
  - If two resource plans have an identical total reserve margin value, but one plan has a 10% GRM and the other a 5% GRM, the 10% GRM plan can provide operators with hundreds of additional MW of reserves (generating and/or load management) during severe peaks
  - A higher GRM plan can also provide operators with significant additional reserves when hurricanes force early shut downs of nuclear units
- A GRM reliability criterion is also desirable from a resource planning perspective because it can lower LOLP projections
- A GRM criterion of a minimum of 10% matches well with Operation's projected need for 2,650 MW of "operational generation reserves" (i.e., generation above forecasted load)

FPL

The 1st topic, "what does an LOLP value mean?", is addressed both by looking at the calculatioı and providing an interpretation

How is an LOLP Value Calculated?

- LOLP calculations project the probability that a utility will not be able to serve 100% of its firm load (i.e., at least 1 MW of firm load cannot be served) during the time period analyzed after all available generation and LM have been used
- LOLP calculations do not provide information regarding: (1) the MW amount that cannot be served; and (2) the duration of the event
- The probability of not being able to serve all firm load is calculated for the peak hour for each day in the year
- These daily probabilities are then summed to derive a monthly probability of not being able to meet firm load on a peak hour during the month
- Then the monthly probabilities are summed to derive an annual probability of not being able to meet firm load on a peak hour during the year
- Thus an LOLP value is a sum of daily probabilities (which can exceed 1.00) and the LOLP value is commonly expressed in terms of "days per year"

 DRAFT Attorney-Client Work Product, Privileged & Confidential

FPL.

A monthly breakdown of previously provided annual LOLP projections is provided below

Monthly Breakdown of Previous LOLP Values

- In the 12/06/2013 presentation, two LOLP values were presented for the year 2021: 0.0358 days/year for a 5% GRM plan and 0.0257 days/year for a 10% GRM plan
- The following table shows a monthly breakdown of these values:

Month	w/ 5% GRM: Projected Days per Individual Month	w/ 5% GRM: Projected Cumulative Days per Year	w/ 10% GRM: Projected Days per Individual Month	w/ 10% GRM: Projected Cumulative Days per Year
January	0.000018	0.0000	0.000003	0.0000
February	0.000000	0.0000	0.000000	0.0000
March	0.000030	0.0000	0.000004	0.0000
April	0.000002	0.0001	0.000001	0.0000
May	0.000065	0.0001	0.000022	0.0000
June	0.001522	0.0016	0.000819	0.0008
July	0.000436	0.0021	0.000351	0.0012
August	0.001456	0.0035	0.001203	0.0024
September	0.031795	0.0353	0.023089	0.0255
October	0.000506	0.0358	0.000210	0.0257
November	0.000000	0.0358	0.000000	0.0257
December	0.000000	0.0358	0.000000	0.0257
Annual Days per Year =		0.0358		0.0257

FPL

LOLP discussion may be "flipped" from "days per year" to "years per day" terms to provide an easier-to-use interpretation

A Useful Interpretation of LOLP Values

- If one assumes that a projected LOLP value for a given year remains constant for each year in an LOLP analysis, one can project how many years will pass before the utility will not be able to meet firm load (i.e., before the sum of the annual LOLP values = 1.0) by dividing the annual LOLP into 1.0

- Some utilities, such as Hawaiian Electric Company, use this "years per day" format when reporting results of LOLP analyses

- The 5% GRM plan had an annual LOLP value of 0.0358 which converts to 27.9 years, and the 10% GRM plan had an annual LOLP value of 0.0257 or 38.9 years, before LOLP sums to 1.0

In this analysis, the 10% GRM plan is projected to allow FPL to meet firm load for 11 more years without an interruption than with the 5% GRM plan

FPL

Regarding the 2nd topic of LM "fatigue", benchmarking data was sought from multiple sources

Benchmarking Results

- **The DSM group contracted with Esource to canvas various industry leaders (utilities / consultants)**
- **No empirical data exists on customer fatigue due to over use of LM, but opinions received are in-line with FPL's view regarding avoiding LM fatigue:**
  - No greater than 10 events/year
  - Events should be spread out throughout the year (e.g., not all in summer or extreme winter events)
  - Events should not be prolonged (e.g., greater than 2-3 hours)
- **Ahmad Faruqui, Ph.D., an industry expert, stated this is a question "for which I have not been able to find any good data"**
  - He implied a range for which fatigue may occur: "Survey results indicate that the maximum realistic call duration for ERCOT is 4 hrs. and frequency should be no greater than 10 events/year."

LM benchmarking on customer fatigue is inconclusive

FPL

The 3rd topic is the relevance of generation reserves to address generation needed prior to hurricane landfall

Generation Margins Needed Pre-Hurricane

- Prior to land fall, loads are high due to customers cooling their homes and lowering refrigerator temperatures
- High loads prior to land fall occur while FPL is shutting down specific units
  - For example, a hurricane impacting the St. Lucie units (almost 2,000 MW of generation/gross output), must go to 60% output as early as 24 hours prior to land fall, and complete shut down at 18 hours prior to hurricane winds at the site.
- Activation of LM due to a capacity shortfall prior to landfall would have an impact on our customers' preparations including efforts to pre-cool their homes
- A generation reserve of approximately 2,650 MW (as discussed on slide 20 – Operational generation reserves) provides additional reliability, allowing service for our customers prior to hurricane impact

Operations prior to hurricane landfall must consider the unavailability of specific generation and impact to customers

FPL

If a hurricane impacts both PTN and PSL, there is high potential to shut down both units

PTN and PSL Impact and Generation Reserves

- Over the past 100 years, multiple hurricanes have impacted the PTN and PSL areas
- In 1960, Hurricane Cleo (Category 2) may have resulted in sustained hurricane force winds at both PTN and PSL (no anemometers in area)
- Both plants, with output of approx. 3,600 MW, would need to shut down if affected

- The operational generation reserves provide additional reliability to mitigate the unavailability of generation prior to hurricane impact

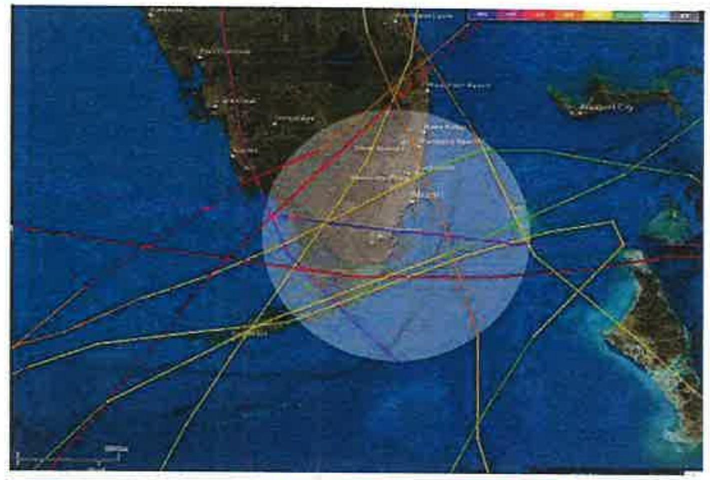
The impact of a hurricane affecting PTN and PSL would require the use of large amounts of LM. Shedding of firm customers is not expected.

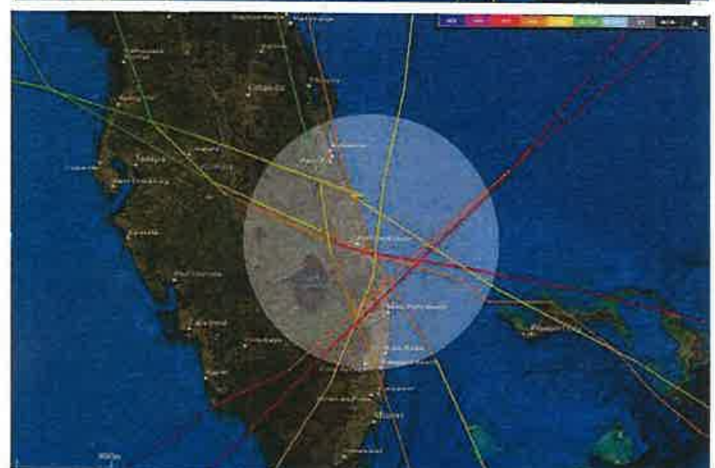
FPL

Generation reserves are needed to account for generation during periods prior to hurricane landfall

Generation Reserves Needed Pre-Hurricane

- **From the period of 1960-2013 eleven hurricanes tracked within 65 nautical miles of Turkey Point and another 8 hurricanes tracked within 65 nautical miles of St. Lucie**
  - Turkey Point hurricanes would reduce the total reserve margin from 21.0% (year 2021) to 13.9%
  - St. Lucie hurricanes would reduce the total reserve margin from 21.0% (year 2021) to 12.2%





The impact from a hurricane to one of the nuclear sites is significant, resulting in the loss of most of the generation reserves and likely needing to use LM

FPL

The 4th topic is that the potential for regulatory implications due to emergency operations declarations

North American Electric Reliability Corporation (NERC) Standards

- **EOP-002 NERC Reliability Standard: Declaration of Energy Emergency Alert (EEA)**
  - FPL's plan based on its interpretation of EOP-002 which is to declare an EEA-2 when LC capability is less (or close to less) than the required reserves necessary to cover the loss of largest FPL unit (FM2 at 1,515 MW by 2021)
    - -- Note: EEA-3 is when load shedding is eminent or underway
  - FPL plan will not result in a declaration for limited (e.g., less than 400 MW) use of LC
    - -- FPL has not declared an EEA under EOP-002
  - From discussions with peers in the Southeast and limited information on NERC website, FPL's practice appears to be consistent with historical declarations in other regions

FPL.

The 4th topic is that the potential for regulatory implications also influences FPL's operating philosophy (Cont'd)

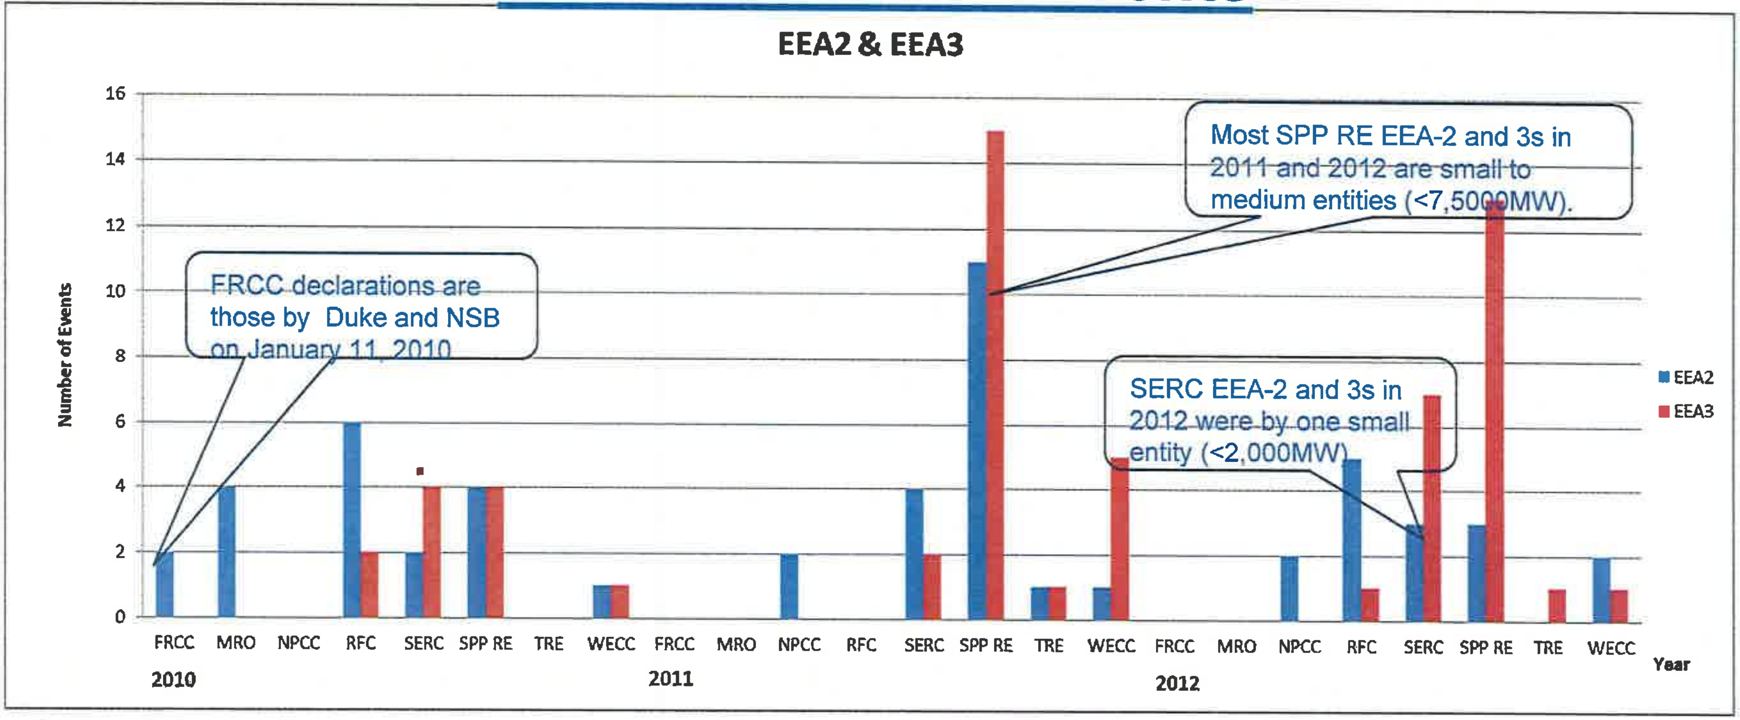
North American Electric Reliability Corporation (NERC) Standards

- **EOP-002 triggers for EEA-2s is not clear, and recognized as such industry-wide**
  - Standard implies that a declaration of an EEA-2 is linked to LC deployment
  - FRCC procedure linking the FRCC Emergency Capacity Plan with EOP-002 does clarify triggers for EEA-2
- **NERC tracks EEA-2s and EEA-3s under EOP-002 to measure the number of events declared during peak load periods, this may serve as leading indicator of capacity shortfall**

FPL

NERC historical tracking of alert declarations varies by region

EEA-2 and EEA-3 Events



- **Legitimate emergencies will be tracked by NERC**
  - NERC states that EEA-2 events calling solely for activation of DSM or interruption of non-firm load will be excluded from the metric in the future as demand response is a legitimate resource and are not of direct concern regarding reliability.

The potential, form, and results of regulatory scrutiny based on what NERC considers too many legitimate emergencies is unclear

FPL.

The need for a new GRM reliability criterion can be supported by 3 points

FPL's Need for a New Reliability Criterion

- **These 3 points (presented in decreasing order of importance) are:**
  1. "All resource plans with identical total reserve margins are not created equal" from an operational perspective (a higher GRM plan will result in significantly more total resources - generation and load management - available for system operators than a lower GRM plan in severe peak conditions)
  2. A resource plan with a higher GRM value is projected to be more reliable from an LOLP perspective (slides 3 through 5)
  3. A resource plan with a higher GRM value is projected to have to use its LM resources less frequently (from 12/06/13 presentation)
- **In regard to point 1 above:**
  - This point can be demonstrated by a "look backwards" analysis of Winter 2010 (slides 15 – 17 and Appendix slides 24 - 27)
  - This point can also be demonstrated by a "looking forward" analysis for Summer and Winter for the year 2021 (slides 18 & 19 and Appendix slides 28 -33)

FPL.

In the "look backwards" analysis, several perspectives were taken of the Winter peak day in 2010

Regarding the January 2010 Peak Day

- The first perspective was of what actually happened on that day (the 2009 Site Plan's projections for the year 2010 were used as the starting point for this analysis)
- The second perspective was to see how FPL's system would have fared if the resource plan had been different with a GRM of 10% in 2010 (but an identical Summer total RM of 20.4%)
- The third perspective was to see how FPL's system would have fared if the resource plan had been different with a GRM of 5% in 2010 (but an identical Summer total RM of 20.4%)

FPL

Sufficient generation reserves are needed for peak load periods

January 11, 2010 (7- 8 AM) – All Time FPL Peak Load

- **Relative to the 2009 Ten Year Site Plan (TYSP), the total reserves for the Winter were 58.2% with a Generation Reserve Margin (GRM) of 42.9%. The Summer reserve margin was 20.4% with an 8.4% GRM**
  - FPL's load was 24,872 MW, 6,196 MW higher than forecasted
  - FPL entered day with 7.4% reserves, all in load management (LM)
  - 24,872 MW of generation was available
  - FPL implemented C/I LM and voltage reduction (561 MW)
  - FPL sold 526 MW of emergency power
  - 1,144 MW of LM remained available during the peak hour
  - No firm load was curtailed by FPL or any other Florida utility
  - Several hours after the peak hour Turkey Point 4 (PTN4) tripped with 750 MW of generation

In Winter 2010, the generation reserves were just sufficient to provide reliable operations with no curtailment of firm load in Florida

Analyses of Winter 2010, using different GRM values, provide a couple of key "takeaways"*

Takeaways from the January 2010 Peak Day Analyses

	Firm Load is Shed?		
Scenario	**W/ TP4**	**W/O TP4**	**Comments**
Actual: 8.4% GRM	No	No	If PTN4 would have tripped prior to the peak, FPL would have implemented additional LM
w/ 10% GRM	No	No	A 10% GRM (as compared to a 5%) would have resulted in a 659 MW increase in LM reserves, and no utilities would have had to shed firm load Similar to the 8.4% GRM scenario, if PTN4 would have tripped prior to the peak, FPL would have implemented additional LM
w/ 5% GRM	No	Yes	W/O TP4 either FPL or another utility in Florida would have had to shed 52 MW of firm load impacting over 30,000 customers

Compared to 8.4%:
+213 w/10%
−446 w/5%
Δ = 659

* The actual analyses are presented in Appendix slides 24 - 27

On 1/11/10, a 5% GRM would have resulted in 30,000 firm load customers being shed, but a 10% GRM would have provided 659 MW of additional reserves

FPL.

A "looking forward" analysis of 2021 addressed both Summer and Winter with 5% and 10% GRM-based resource plans

How the Analyses of 2021 Were Conducted

- The 2013 Site Plan's resource plan for the year 2021 was the starting point: 6.9% GRM, 21.0% Summer total RM, and 34.5% Winter total RM
- Then two alternate resource plans with the same 21.0% Summer total RM, but either 5% or 10% Summer GRM were "constructed" for Summer (comparable alternate resource plans for Winter 2021 were also constructed)
- To simplify the analysis, the alternate plans differed in regard to EE and generation only (similar results would occur if LM instead of EE had been varied in the plans)
- Identical changes of 9% were made to forecasted load, EE, and available generation (the percentage change chosen is arbitrary, but reasonable and consistent)
- The resulting available generation and total resources remaining after these changes were made are compared (note that EE's impact has already "happened" at the peak)

FPL

The "looking forward" analyses of resource plans for 2021 provides additional support for a 10% GRM-based resource plan compared to a 5% GRM-based plan

Key Points from the "Looking Forward" Analyses

- Only the 10% GRM-based resource plan is projected to allow FPL to meet firm load in both Summer and Winter of 2021
- Furthermore, when comparing the two GRM-based resource plans, the 10% GRM-based plan provides significantly more MW of resources for both Summer and Winter

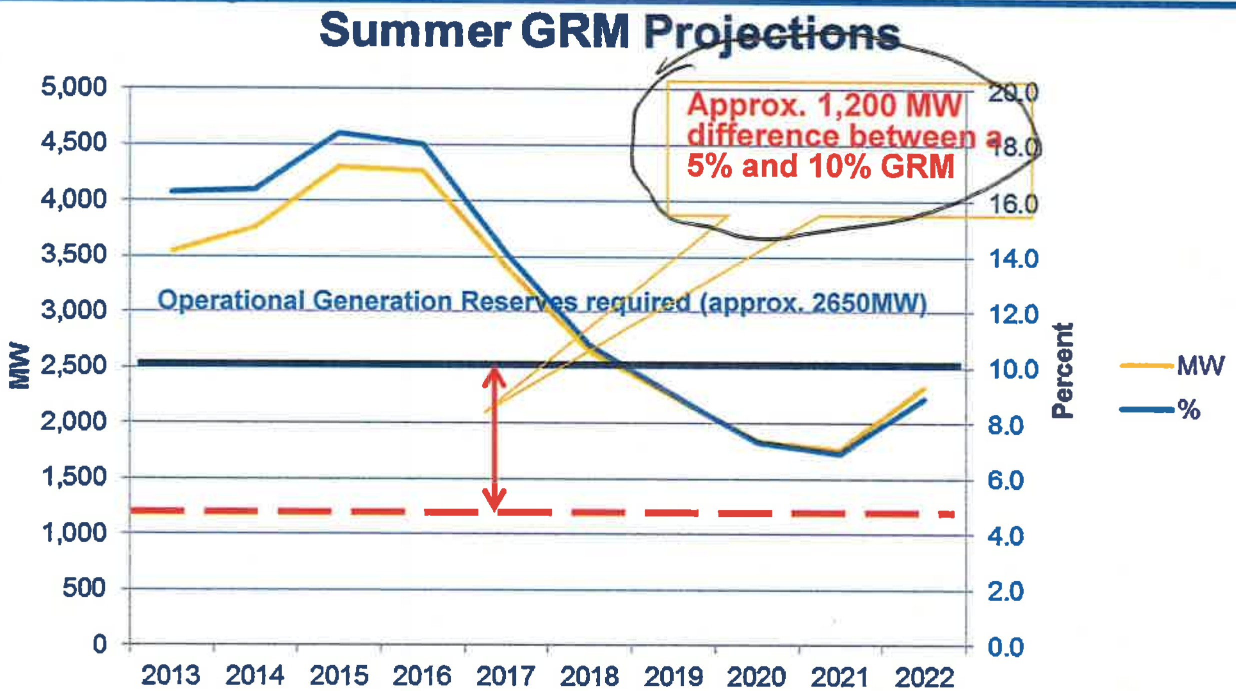
	Summer of 2021			Winter of 2021		
	w/ 10% GRM	w/ 5% GRM	Increased Total Reserves w/ 10% GRM	w/ 10% GRM	w/ 5% GRM	Increased Total Reserves w/ 10% GRM
Total Reserves Remaining after Load, EE, and Generation Adjustments	34	(169)	202	2,921	2,193	728

This "looking forward" analysis again shows system operators will have more resources for their use with a 10% GRM, rather than a 5% GRM, resource plan

FPL

A 10% GRM criterion is a reasonable, easy-to-articulate proxy for FPL's operational generation reserves need

GRM Projections from FPL's 2013 Site Plan



- **FPL's goal is to maintain ~ 2,650 MW of Operational Generation Reserves to cover the following operational situations:**
  - ≈ 700 - Expected unavailable generation (687 MW)
  - ≈ 1,500 - The generation loss of the largest the largest unit (1,515 MW)
  - 450 - Real time operating reserves deployable within 15 minutes as part of the Florida Reserve Sharing Group (450 MW by 2021)

2,650

A 10% GRM is consistent with FPL's required operational reserves

FPL.

FPL has begun using the new GRM criterion in its resource planning process and in 2014 analyses to be filed w/ the FPSC

Next Steps regarding the GRM Criterion

- Text explaining why FPL is using the new criterion will be included in the 2014 TYSP filing and as part of the DSM Goals testimony
- The explanation focuses on analyses comparing resource plans with 10% GRM vs. 5% GRM and include these key points :
  - A 10% GRM results in hundreds of MW of additional operational reserves on severe peak days
  - A 10% GRM results in lower LOLP projections
  - A 10% GRM criterion matches well with the approximately 2,650 MW of generation reserves necessary for operations
- Analyses supporting the 2014 TYSP and DSM Goals filings in April, and the 2014 NCRC filing in early May, all are using the 10% GRM criterion
- These analyses all assume that the 10% GRM criterion must be met beginning in the Summer of 2019

FPL

FPL is not making a separate filing seeking official FPSC approval for FPL's GRM criterion

Next Steps regarding the GRM Criterion (Continued)

- No separate filing/request seeking official FPSC approval for the new GRM criterion will be made
- The only time the FPSC has officially approved a reliability criterion is in the late 1990s when it approved the voluntary stipulation by FPL, TECO, and DEF to move from a 15% to a 20% total reserve margin criterion to close an FPSC docket examining Florida reserves
- TECO did not request approval for its similar supply side reserve margin which it has been using for approximately 10 years
- It is anticipated that discovery requests focused on the new GRM criterion will be received in regard to both the TYSP and DSM Goals filings

FPL

Appendix

FPL and others utilities in Florida were marginally able to serve their entire firm load and FPL met its operational reserve requirements with an 8.4% GRM

Creation of Revised 10% GRM Summer Plan and Corresponding Winter Plan											
Modify the 2009 TYSP resource plan for Summer 2010 to achieve a 10% GRM	23,262	21,147	(72)	21,219	1,899	19,320	3,941	20.4%	2,115	10.0%	---
Using Winter vs Summer differentials, and the modified Summer resource plan, create a comparable resource plan for Winter 2010	27,216	18,790	(37)	18,827	1,705	17,122	10,094	59.0%	8,426	44.8%	Yes
Load Adjustments on Jan 2010 peak day											
Increase in FPL load served after EE but prior to LM utilization				6,231							
Resulting operating conditions on 2010 Winter peak hour due to load	27,216		(37)	25,058	1,705	23,353	3,863	16.5%	2,158	8.6%	Yes
Generation / Load Management / Further FPL Load Adjustments of on Jan 2010 peak day											
	(1,980)			(561)	(561)						
Resulting operating conditions on 2010 Winter peak hour w/ load, LM, & generation adjustments	25,236			24,497	1,144	23,353	1,883	8.1%	739	3.0%	Yes
Emergency Sales Adjustments on Jan 2010 peak day											
Emergency sales				526							
Resulting operating conditions on 2010 Winter peak hour w/ load, LM, & generation adjustments+Em. Sales	25,236			25,023	1,144	23,879	1,357	5.7%	213	0.9%	Yes
TP Unit 4 Nuclear Trip on Jan 2010 prior to peak day											
TP Nuclear Adjustment	(750)			(750)	(750)						
Resulting operating conditions on 2010 Winter peak hour w/ load, LM, generation & TP adjustments	24,486			24,273	394	23,879	607	2.5%	213	0.9%	Yes

* The 2010 Tony letter showed FPL unit capability as 23,333 MW for Winter 2010 & 22,142 MW for Summer. The Winter/Summer ratio is 1.054.

FPL's generation and LM resources would have been greater with a 10% GRM than with 8.4% GRM

 DRAFT Attorney-Client Work Product, Privileged & Confidential

FPL

The second "what if" analysis examined how FPL would have fared if it had entered Winter 2010 with a lower (5%) GRM

"What If"for January 2010 Peak Day w/ 5% GRM

	(1)	(2)	(3)	(4) = (2) - (3)	(5)	(6) = (4) - (5)	(7) = (1) - (6)	(8) = (7) / (6)	(9) = (1) - (2) or = (1) - (4)	(10) = (9) / (2)	(11)
	Total Projected Capacity	Forecasted Peak Load	Forecasted Utility EE	Peak Load After EE	Forecasted LM (w/o scram MW)	Forecasted Firm Load After EE and LM	Total Reserves	Total Reserve Margin as % of Firm Load	Generation Reserves	Generation Reserve Margin	All firm load served by FPL and/or other FL utility?
	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(%)	(MW)	(%)	—
Creation of Revised 5% GRM Summer Plan and Corresponding Winter Plan											
Modify the 2009 TYSP resource plan for Summer 2010 to achieve a 5% GRM	22,204	21,147	806	20,341	1,899	18,442	3,762	20.4%	1,057	5.0%	—
Using Winter vs Summer differentials, and the modified Summer resource plan, create a comparable resource plan for Winter 2010	26,102	18,790	418	18,372	1,705	16,667	9,435	56.6%	7,312	38.9%	Yes
Load Adjustments on Jan 2010 peak day											
Increase in FPL load served after EE but prior to LM utilization				6,231							
Resulting operating conditions on 2010 Winter peak hour due to load	26,102		418	24,603	1,705	22,898	3,204	14.0%	1,499	6.1%	Yes
Generation / Load Management / Further FPL Load Adjustments of on Jan 2010 peak day											
	(1,980)			(561)	(561)						
Resulting operating conditions on 2010 Winter peak hour w/ load, LM, & generation adjustments	24,122			24,042	1,144	22,898	1,224	5.3%	60	0.3%	Yes
Emergency Sales Adjustments on Jan 2010 peak day											
Emergency sales				526							
Resulting operating conditions on 2010 Winter peak hour w/ load, LM, & generation adjustments+Em. Sales	24,122			24,568	1,144	23,424	698	3.0%	[illegible]	-1.8%	No
TP Unit 4 Nuclear Trip on Jan 2010 prior to peak day											
TP Nuclear Adjustment	(750)			(750)	(750)						
Resulting operating conditions on 2010 Winter peak hour w/ load, LM, generation & TP adjustments	23,372			23,818	394	23,424	[illegible]	-0.2%	[illegible]	-1.9%	No

* The 2010 Tony letter showed FPL unit capability as 23,333 MW for Winter 2010 & 22,142 MW for Summer. The Winter/Summer ratio is 1.054.

Even after exhausting FPL's generation and LM resources, FPL would not have been able to meet its firm load with a 5% GRM

FPL

Regarding a "look forward" to 2021, the 5% Summer GRM-based resource plan was examined first in regard to Summer peak

"What If" Summer 2021 Peak Day w/ 5% GRM

Summer	Total Projected Capacity	Forecasted Peak Load	Forecasted Utility EE	Peak Load After EE	Forecasted LC	Forecasted Firm Load After EE and LC	Total Reserves	Total Reserve Margin as % of Firm Load	Generation Reserves	GRM
	(1)	(2)	(3)	(4) = (2) - (3)	(5)	(6) = (4) - (5)	(7) = (1) - (6)	(8) = (7) / (6)	(9) = (1) - (2) or = (1) - (4)	(10) = (9) / (2)
	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(%)	(MW)	(%)
5% GRM resource plan	26,838	25,560	1,230	24,330	2,150	22,180	4,658	21.0%	1,278	5.0%
Higher-than-Projected Peak Load *		2,300								
Lower-than-projected EE Reduction *			(111)							
Resulting actual operating conditions on 2021 peak hour	26,838	27,860	1,119	26,741	2,150	24,591	2,247	9.1%	97	0.3%
Unavailable Generation *	(2,415)									
Resulting actual operating conditions on 2021 peak hour after Generation Adjustment	24,423	27,860	1,119	26,741	2,150	24,591	(169)	-0.7%	(2,319)	-8.3%

* A 9% adjustment was made to the starting point value in the first row.

With the 5% GRM plan, FPL would not be able to meet Summer firm load (as seen by the negative 169 MW) of Total Reserves in Col. 7)

FPL

The 10% Summer GRM-based resource plan was examined next in regard to Summer peak

"What If" Summer 2021 Peak Day w/ 10% GRM

Summer	Total Projected Capacity	Forecasted Peak Load	Forecasted Utility EE	Peak Load After EE	Forecasted LC	Forecasted Firm Load After EE and LC	Total Reserves	Total Reserve Margin as % of Firm Load	Generation Reserves	GRM
	(1)	(2)	(3)	(4) = (2) - (3)	(5)	(6) = (4) - (5)	(7) = (1) - (6)	(8) = (7) / (6)	(9) = (1) - (2) or = (1) - (4)	(10) = (9) / (2)
	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(%)	(MW)	(%)
10% GRM resource plan	28,116	25,560	174	25,386	2,150	23,236	4,880	21.0%	2,556	10.0%
Higher-than-Projected Peak Load *		2,300								
Lower-than-projected EE Reduction *			(16)							
Resulting actual operating conditions on 2021 peak hour	28,116	27,860	158	27,702	2,150	25,552	2,564	10.0%	414	1.5%
Unavailable Generation *	(2,530)									
Resulting actual operating conditions on 2021 peak hour after Generation Adjustment	25,586	27,860	158	27,702	2,150	25,552	34	0.1%	(2,117)	-7.6%

* A 9% adjustment was made to the starting point value in the first row.

With the 10% GRM plan, FPL would be able to meet Summer firm load (as seen by the positive 34 MW of Total Reserves)

FPL

The 5% Summer GRM-based resource plan was examined next in regard to Winter peak

"What If" Winter 2021 Peak Day w/ 5% GRM

Winter	Total Projected Capacity	Forecasted Peak Load	Forecasted Utility EE	Peak Load After EE	Forecasted LC	Forecasted Firm Load After EE and LC	Total Reserves	Total Reserve Margin as % of Firm Load	Generation Reserves	GRM
	(1)	(2)	(3)	(4) = (2) - (3)	(5)	(6) = (4) - (5)	(7) = (1) - (6)	(8) = (7) / (6)	(9) = (1) - (2) or = (1) - (4)	(10) = (9) / (2)
	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(%)	(MW)	(%)
Winter resource plan corresponding to the Summer plan w/ 5% GRM	28,287	23,601	637	22,964	1,597	21,367	6,920	32.4%	4,686	19.9%
Higher-than-Projected Peak Load *		2,124								
Lower-than-projected EE Reduction *			(57)							
Resulting actual operating conditions on 2021 peak hour	28,287	25,725	580	25,145	1,597	23,548	4,739	20.1%	3,142	12.2%
Unavailable Generation *	(2,546)									
Resulting actual operating conditions on 2021 peak hour after Generation Adjustment	25,741	25,725	580	25,145	1,597	23,548	2,193	9.3%	596	2.3%

* A 9% adjustment was made to the starting point value in the first row.

With the 5% GRM resource plan, FPL would be able to meet Winter firm load with 2,193 MW of Total Reserves to spare

FPL

The 10% Summer GRM-based resource plan was then examined in regard to Winter peak

"What If" Winter 2021 Peak Day w/ 10% GRM

Winter	Total Projected Capacity	Forecasted Peak Load	Forecasted Utility EE	Peak Load After EE	Forecasted LC	Forecasted Firm Load After EE and LC	Total Reserves	Total Reserve Margin as % of Firm Load	Generation Reserves	GRM
	(1)	(2)	(3)	(4) = (2) - (3)	(5)	(6) = (4) - (5)	(7) = (1) - (6)	(8) = (7) / (6)	(9) = (1) - (2) or	(10) = (9) / (2)
	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(%)	(MW)	(%)
Winter resource plan corresponding to the Summer plan w/ 10% GRM	29,634	23,601	90	23,511	1,597	21,914	7,720	35.2%	6,033	25.6%
Higher-than-Projected Peak Load *		2,124								
Lower-than-projected EE Reduction *			(8)							
Resulting actual operating conditions on 2021 peak hour	29,634	25,725	82	25,643	1,597	24,046	5,588	23.2%	3,991	15.5%
Unavailable Generation *	(2,667)									
Resulting actual operating conditions on 2021 peak hour after Generation Adjustment	26,967	25,725	82	25,643	1,597	24,046	2,921	12.1%	1,324	5.1%

* A 9% adjustment was made to the starting point value in the first row.

With the 10% GRM resource plan, FPL would be able to meet Winter firm load with 2,921 MW of Total Reserves to spare

FPL

Another "look forward to 2021" case was analyzed in which LM, not EE, was allowed to vary

"What If" Summer 2021 Peak Day w/ 5% GRM & LM Varying

Summer	Total Projected Capacity	Forecasted Peak Load	Forecasted Utility EE	Peak Load After EE	Forecasted LC	Forecasted Firm Load After EE and LC	Total Reserves	Total Reserve Margin as % of Firm Load	Generation Reserves	GRM
	(1)	(2)	(3)	(4) = (2) - (3)	(5)	(6) = (4) - (5)	(7) = (1) - (6)	(8) = (7) / (6)	(9) = (1) - (2) or = (1) - (4)	(10) = (9) / (2)
	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(MW)	(%)	(MW)	(%)
5% GRM resource plan	26,838	25,560	830	24,730	2,550	22,180	4,658	21.0%	1,278	5.0%
Higher-than-Projected Peak Load *		2,300								
Lower-than-projected EE and LM Reduction *					(230)					
Resulting actual operating conditions on 2021 peak hour	26,838	27,860	830	27,030	2,321	24,710	2,128	8.6%	-192	-0.7%
Unavailable Generation *	(2,415)									
Resulting actual operating conditions on 2021 peak hour after Generation Adjustment	24,423	27,860	830	27,030	2,321	24,710	(287)	-1.2%	(2,608)	-9.4%

* A 9% adjustment was made to the starting point value in the first row.

With the 5% GRM plan, FPL would not be able to meet Summer firm load (as seen by the negative 287 MW of Total Reserves in Col. 7)

 DRAFT Attorney-Client Work Product, Privileged & Confidential

FPL

Another "look forward to 2021" case was analyzed in which LM, not EE, was allowed to vary - continued

"What If" Summer 2021 Peak Day w/ 10% GRM & LM Varying

Summer	Total Projected Capacity (MW)	Forecasted Peak Load (MW)	Forecasted Utility EE (MW)	Peak Load After EE (MW)	Forecasted LC (MW)	Forecasted Firm Load After EE and LC (MW)	Total Reserves (MW)	Total Reserve Margin as % of Firm Load (%)	Generation Reserves (MW)	GRM (%)
10% GRM resource plan	28,116	25,560	830	24,730	1,494	23,236	4,880	21.0%	2,556	10.0%
Lower-than-projected EE and LM Reduction *		2,300								
Lower-than-projected EE Reduction *					(134)					
Resulting actual operating conditions on 2021 peak hour	28,116	27,860	830	27,030	1,360	25,671	2,445	9.5%	1,086	3.9%
Unavailable Generation *	(2,530)									
Resulting actual operating conditions on 2021 peak hour after Generation Adjustment	25,586	27,860	830	27,030	1,360	25,671	(85)	-0.3%	(1,445)	-5.2%

* A 9% adjustment was made to the starting point value in the first row.

With the 10% GRM plan, FPL comes closer to meeting Summer firm load (as seen by the negative 85 MW of Total Reserves in Col. 7)

FPL

1035 Santa Barbara St, Suite 8 808-987-0389
Santa Barbara, CA 93101 mimsconsultllc@gmail.com

RELEVANT WORK EXPERIENCE

MIMS CONSULTING, LLC
Principal, April 2015 - current

SOUTHERN ALLIANCE FOR CLEAN ENERGY
Energy Efficiency Director, January 2013 - current
Earlier position: Energy Policy Manager, October 2010– December 2012

- Testifies as expert witness before the Public Service Commissions on energy efficiency cost recovery, program plans and financial incentive mechanisms in Georgia, North Carolina and South Carolina
- Responsible for ongoing energy efficiency portfolio and program level quantitative and qualitative research and analysis of major utilities in the Southeast
- Track and participate in energy efficiency regulatory proceedings. Current regulatory proceedings include IRP, cost-recovery filings, energy efficiency program pilots and existing program modifications
- Responsible for reviewing and writing comments and/or testimony for all major energy efficiency regulatory proceedings for utilities in Tennessee, North and South Carolina, Georgia and Florida
- Responsible for managing energy efficiency staff and establishing and implementing efficiency strategy for the SACE
- Assists in development/fundraising to ensure energy efficiency work funded in upcoming years
- Lead participant for SACE at TVA, Duke Energy and Georgia Power energy efficiency working groups

ROCKY MOUNTAIN INSTITUTE
Senior Consultant, July 2009 – October 2010
Earlier positions: Intern, Fellow, Analyst, and Consultant October 2004- July 2009

- Project manager for nine-person team creating energy efficiency component of national analysis to eliminate US fossil fuel consumption by 2050
- Project manager for company-wide energy efficiency strategy and development
- Lead on energy efficiency analysis for major southeastern IOU low-carbon strategy
- Lead author on published national analysis on electric productivity
- Member of senior leadership of Energy and Resources Team at the organization. Contributed to team strategy, resource planning and staffing for 12-20 person team and hiring as well as organizational professional development strategy
- Contributed to writing Hawaii Energy Strategy 2007 and planning Hawaii Biofuels Summit Contributed to RMI filings in Energy Efficiency docket before Hawaii Public Utility Commission
- Participated in Hawaii Energy Policy Forum Energy Efficiency working group
- Significant contributor to consulting and research projects including: national and state energy policies, utility revenue adjustment mechanisms, utility regulatory structures, private sector investment in energy efficiency, corporate carbon management strategy, renewable energy market assessments, large and small scale sustainable development projects, Hawaii agricultural sustainability barriers and solutions

PUBLICATIONS

Summary

Nationally recognized leader and innovator in electricity and energy law, policy, and regulation. Experienced as a public utility regulatory commissioner, educator, research and development program manager, utility executive, business builder, federal executive, corporate sustainability leader, consultant, and advocate. Thought leader and practice expert in organizational transformation. Highly proficient in advising, managing, and interacting with government agencies and committees, the media, citizen groups, and business associations. Successful track record of working with US Congress, state legislatures, governors, regulators, city councils, business leaders, researchers, academia, and community groups. National and international contacts through experience with Austin Energy, AES Corporation, US Department of Energy, Texas Public Utility Commission, Jicarilla Apache Tribal Utility Authority, Cargill Dow LLC (now NatureWorks, LLC), Rocky Mountain Institute, CH2M HILL, Houston Advanced Research Center, Environmental Defense Fund, and others. Skilled attorney, negotiator, and advisor with more than twenty years experience working with diverse stakeholder communities in electricity policy and regulation, emerging energy markets development, clean energy technology development, electric utility restructuring, smart grid development, and the implementation of sustainability principles. Extensive regulatory practice experience. Nationally recognized speaker on energy, environment and sustainable development matters. Managed staff as large as 250; responsible for operations of research facilities with staff in excess of 600. Developed and managed budgets in excess of $300 million. Law teaching experience at University of Houston Law Center and U.S. Military Academy at West Point. Trial experience as a Judge Advocate. Post doctorate degrees in environmental and military law. Military veteran.

Employment

PACE ENERGY AND CLIMATE CENTER, PACE UNIVERSITY SCHOOL OF LAW

Executive Director: May 2014—Present.

Leader of a team of professional and technical experts in energy and climate law, policy, and regulation. Secure funding for and manage execution of research, market development support, and advisory services for a wide range of funders, clients, and stakeholders with the overall goal of advancing clean energy deployment, climate responsibility, and market efficiency. Supervise a team of employees, consultants, and adjunct researchers. Provide learning and development opportunities for law students. Coordinate efforts of the Center with and support the environmental law faculty. Additional activities:

- Co-Director and Principal Investigator, Northeast Solar Energy Market Coalition (2015-present). The NESEMC is a US Department of Energy's SunShot Initiative Solar Market Pathways project. Funded under a cooperative agreement between the US DOE and Pace University, the NESEMC seeks to harmonize solar market policy and advance best policy and regulatory practices in the northeast United States.
- Chairman of the Board, Center for Resource Solutions (1997-present). CRS is a not-for-profit organization based at the Presidio in California. CRS developed and manages the Green-e Renewable Electricity Brand, a nationally and internationally recognized branding program for green power and green pricing products and programs. Past chair of the Green-e Governance Board (formerly the Green Power Board).

- Director, Interstate Renewable Energy Council (IREC) (2012-present). IREC focuses on issues impacting expanded renewable energy use such as rules that support renewable energy and distributed resources in a restructured market, connecting small-scale renewables to the utility grid, developing quality credentials that indicate a level of knowledge and skills competency for renewable energy professionals.

RÁBAGO ENERGY LLC

Principal: July 2012—Present. Consulting practice dedicated to providing expert witness and policy formulation advice and services to organizations in the clean and advanced energy sectors. Recognized national leader in development and implementation of award-winning "Value of Solar" alternative to traditional net metering. Additional information at www.rabagoenergy.com.

AUSTIN ENERGY – THE CITY OF AUSTIN, TEXAS

Vice President, Distributed Energy Services: April 2009—June 2012. Executive in 8th largest public power electric utility serving more than one million people in central Texas. Responsible for management and oversight of energy efficiency, demand response, and conservation programs; low-income weatherization; distributed solar and other renewable energy technologies; green buildings program; key accounts relationships; electric vehicle infrastructure; and market research and product development. Executive sponsor of Austin Energy's participation in an innovative federally-funded smart grid demonstration project led by the Pecan Street Project. Led teams that successfully secured over $39 million in federal stimulus funds for energy efficiency, smart grid, and advanced electric transportation initiatives. Additional activities included:

- Director, Renewable Energy Markets Association. REMA is a trade association dedicated to maintaining and strengthening renewable energy markets in the United States.
- Membership on Pedernales Electric Cooperative Member Advisory Board. Invited by the Board of Directors to sit on first-ever board to provide formal input and guidance on energy efficiency and renewable energy issues for the nation's largest electric cooperative.

THE AES CORPORATION

Director, Government & Regulatory Affairs: June 2006—December 2008. Government and regulatory affairs manager for AES Wind Generation, one of the largest wind companies in the country. Manage a portfolio of regulatory and legislative initiatives to support wind energy market development in Texas, across the United States, and in many international markets. Active in national policy and the wind industry through work with the American Wind Energy Association as a participant on the organization's leadership council. Also served as Managing Director, Standards and Practices, for Greenhouse Gas Services, LLC, a GE and AES venture committed to generating and marketing greenhouse gas credits to the U.S. voluntary market. Authored and implemented a standard of practice based on ISO 14064 and industry best practices. Commissioned the development of a suite of methodologies and tools for various greenhouse gas credit-producing technologies. Also served as Director, Global Regulatory Affairs, providing regulatory support and group management to AES's international electric utility operations on five continents. Additional activities:

- Director and past Chair, Jicarilla Apache Nation Utility Authority (1998 to 2008). Located in New Mexico, the JAUA is an independent utility developing profitable and autonomous utility services that provides natural gas, water utility services, low income housing, and energy planning for the Nation. Authored "First Steps" renewable energy and energy efficiency strategic plan.

Karl R. Rábago

HOUSTON ADVANCED RESEARCH CENTER

Group Director, Energy and Buildings Solutions: December 2003—May 2006. Leader of energy and building science staff at a mission-driven not-for-profit contract research organization based in The Woodlands, Texas. Responsible for developing, maintaining and expanding upon technology development, application, and commercialization support programmatic activities, including the Center for Fuel Cell Research and Applications, an industry-driven testing and evaluation center for near-commercial fuel cell generators; the Gulf Coast Combined Heat and Power Application Center, a state and federally funded initiative; and the High Performance Green Buildings Practice, a consulting and outreach initiative. Secured funding for major new initiative in carbon nanotechnology applications in the energy sector. Developed and launched new and integrated program activities relating to hydrogen energy technologies, combined heat and power, distributed energy resources, renewable energy, energy efficiency, green buildings, and regional clean energy development. Active participant in policy development and regulatory implementation in Texas, the Southwest, and national venues. Frequently engaged with policy, regulatory, and market leaders in the region and internationally. Additional activities:

- President, Texas Renewable Energy Industries Association. As elected president of the statewide business association, leader and manager of successful efforts to secure and implement significant expansion of the state's renewable portfolio standard as well as other policy, regulatory, and market development activities.
- Director, Southwest Biofuels Initiative. Established the Initiative acts as an umbrella structure for a number of biofuels related projects, including emissions evaluation for a stationary biodiesel pilot project, feedstock development, and others.
- Member, Committee to Study the Environmental Impacts of Windpower, National Academies of Science National Research Council. The Committee was chartered by Congress and the Council on Environmental Quality to assess the impacts of wind power on the environment.
- Advisory Board Member, Environmental & Energy Law & Policy Journal, University of Houston Law Center.

CARGILL DOW LLC (NOW NATUREWORKS, LLC)

Sustainability Alliances Leader: April 2002—December 2003. Founded in 1997, NatureWorks, LLC is based in Minnetonka, Minnesota. Integrated sustainability principles into all aspects of a ground-breaking biobased polymer manufacturing venture. Responsible for maintaining, enhancing and building relationships with stakeholders in the worldwide sustainability community, as well as managing corporate and external sustainability initiatives. NatureWorks is the first company to offer its customers a family of polymers (polylactide – "PLA") derived entirely from annually renewable resources with the cost and performance necessary to compete with packaging materials and traditional fibers; now marketed under the brand name "Ingeo."

- Successfully completed Minnesota Management Institute at University of Minnesota Carlson School of Management, an alternative to an executive MBA program that surveyed fundamentals and new developments in finance, accounting, operations management, strategic planning, and human resource management.

ROCKY MOUNTAIN INSTITUTE

Managing Director/Principal: October 1999–April 2002. In two years, co-led the team and grew annual revenues from approximately $300,000 to more than $2 million in annual grant and consulting income. Co-authored "Small Is Profitable," a comprehensive analysis of the benefits of distributed energy resources. Worked to increase market opportunities for clean and distributed energy resources through consulting, research, and publication activities. Provided consulting and advisory services to help business and government clients achieve sustainability through application and incorporation of Natural Capitalism principles. Frequent appearance in media at international, national, regional and local levels.

- President of the Board, Texas Ratepayers Organization to Save Energy. Texas R.O.S.E. is a non-profit organization advocating low-income consumer issues and energy efficiency programs.
- Co-Founder and Chair of the Advisory Board, Renewable Energy Policy Project-Center for Renewable Energy and Sustainable Technology. REPP-CREST was a national non-profit research and internet services organization.

CH2M HILL

Vice President, Energy, Environment and Systems Group: July 1998–August 1999. Responsible for providing consulting services to a wide range of energy-related businesses and organizations, and for creating new business opportunities in the energy industry for an established engineering and consulting firm. Completed comprehensive electric utility restructuring studies for the states of Colorado and Alaska.

PLANERGY

Vice President, New Energy Markets: January 1998–July 1998. Responsible for developing and managing new business opportunities for the energy services market. Provided consulting and advisory services to utility and energy service companies.

ENVIRONMENTAL DEFENSE FUND

Energy Program Manager: March 1996–January 1998. Managed renewable energy, energy efficiency, and electric utility restructuring programs for a not-for-profit environmental group with a staff of 160 and over 300,000 members. Led regulatory intervention activities in Texas and California. In Texas, played a key role in crafting Deliberative Polling processes. Initiated and managed nationwide collaborative activities aimed at increasing use of renewable energy and energy efficiency technologies in the electric utility industry, including the Green-e Certification Program, Power Scorecard, and others. Participated in national environmental and energy advocacy networks, including the Energy Advocates Network, the National Wind Coordinating Committee, the NCSL Advisory Committee on Energy, and the PV-COMPACT Coordinating Council. Frequently appeared before the Texas Legislature, Austin City Council, and regulatory commissions on electric restructuring issues.

UNITED STATES DEPARTMENT OF ENERGY

Deputy Assistant Secretary, Utility Technologies: January 1995–March 1996. Manager of the Department's programs in renewable energy technologies and systems, electric energy systems, energy efficiency, and integrated resource planning. Supervised technology research, development and deployment activities in photovoltaics, wind energy, geothermal energy, solar thermal energy, biomass energy, high-temperature superconductivity, transmission and distribution, hydrogen, and electric and magnetic fields. Developed, coordinated, and advised on legislation, policy, and renewable energy technology development within the Department, among other agencies, and with Congress. Managed, coordinated, and developed international agreements for cooperative activities in renewable energy and utility sector policy, regulation, and market development between the Department and counterpart foreign national entities. Established and enhanced partnerships with stakeholder groups, including technology firms, electric utility companies, state and local governments, and associations. Supervised development and deployment support activities at national laboratories. Developed, advocated and managed a Congressional budget appropriation of approximately $300 million.

STATE OF TEXAS

Commissioner, Public Utility Commission of Texas. May 1992–December 1994. Appointed by Governor Ann W. Richards. Regulated electric and telephone utilities in Texas. Laid the groundwork for legislative and regulatory adoption of integrated resource planning, electric utility restructuring, and significantly increased use of renewable energy and energy efficiency resources. Appointed by Governor Richards to co-chair and organize the Texas Sustainable Energy Development Council. Served as Vice-Chair of the National Association of Regulatory Utility Commissioners (NARUC) Committee on Energy Conservation. Member and co-creator of the Photovoltaic Collaborative Market Project to Accelerate Commercial Technology (PV-COMPACT), a nationwide program to develop domestic markets for photovoltaics. Member, Southern States Energy Board Integrated Resource Planning Task Force. Member of the University of Houston Environmental Institute Board of Advisors.

LAW TEACHING

Professor for a Designated Service: Pace University Law School, 2014-present. Non-tenured member of faculty. Courses taught: Energy Law. Supervise a student clinical effort that engages in a wide range of advocacy, analysis, and research activities in support of the mission of the Pace Energy and Climate Center.

Associate Professor of Law: University of Houston Law Center, 1990–1992. Full time, tenure track member of faculty. Courses taught: Criminal Law, Environmental Law, Criminal Procedure, Environmental Crimes Seminar, Wildlife Protection Law. Provided *pro bono* legal services in administrative proceedings and filings at the Texas Public Utility Commission. Launched a student clinical effort that reviewed and made recommendations on utility energy efficiency program plans.

Assistant Professor: United States Military Academy, West Point, New York, 1988–1990. Member of the faculty in the Department of Law. Honorably discharged in August 1990, as Major in the Regular Army. Courses taught: Constitutional Law, Military Law, and Environmental Law Seminar. Greatly expanded the environmental law curriculum and laid foundation for the concentration program in law. While carrying a full time teaching load, earned a Master of Laws degree in Environmental Law. Established a program for subsequent environmental law professors to obtain an LL.M. prior to joining the faculty.

LITIGATION

Trial Defense Attorney and Prosecutor, U.S. Army Judge Advocate General's Corps, Fort Polk, Louisiana, January 1985–July 1987. Assigned to Trial Defense Service and Office of the Staff Judge Advocate. Prosecuted and defended more than 150 felony-level courts-martial. As prosecutor, served as legal officer for two brigade-sized units (approximately 5,000 soldiers), advising commanders on appropriate judicial, non-judicial, separation, and other actions. Pioneered use of some forms of psychiatric and scientific testimony in administrative and judicial proceedings.

NON-LEGAL MILITARY SERVICE

Armored Cavalry Officer, 2d Squadron 9th Armored Cavalry, Fort Stewart, Georgia, May 1978–August 1981. Served as Logistics Staff Officer (S-4). Managed budget, supplies, fuel, ammunition, and other support for an Armored Cavalry Squadron. Served as Support Platoon Leader for the Squadron (logistical support), and as line Platoon Leader in an Armored Cavalry

Troop. Graduate of Airborne and Ranger Schools. Special training in Air Mobilization Planning and Nuclear, Biological and Chemical Warfare.

Karl R. Rábago

Formal Education

LL.M., Environmental Law, Pace University School of Law, 1990: Curriculum designed to provide breadth and depth in study of theoretical and practical aspects of environmental law. Courses included: International and Comparative Environmental Law, Conservation Law, Land Use Law, Seminar in Electric Utility Regulation, Scientific and Technical Issues Affecting Environmental Law, Environmental Regulation of Real Estate, Hazardous Wastes Law. Individual research with Hudson Riverkeeper Fund, Garrison, New York.

LL.M., Military Law, U.S. Army Judge Advocate General's School, 1988: Curriculum designed to prepare Judge Advocates for senior level staff service. Courses included: Administrative Law, Defensive Federal Litigation, Government Information Practices, Advanced Federal Litigation, Federal Tort Claims Act Seminar, Legal Writing and Communications, Comparative International Law.

J.D. with Honors, University of Texas School of Law, 1984: Attended law school under the U.S. Army Funded Legal Education Program, a fully funded scholarship awarded to 25 or fewer officers each year. Served as Editor-in-Chief (1983–84); Articles Editor (1982–83); Member (1982) of the Review of Litigation. Moot Court, Mock Trial, Board of Advocates. Summer internship at Staff Judge Advocate's offices. Prosecuted first cases prior to entering law school.

B.B.A., Business Management, Texas A&M University, 1977: ROTC Scholarship (3–yr). Member: Corps of Cadets, Parson's Mounted Cavalry, Wings & Sabers Scholarship Society, Rudder's Rangers, Town Hall Society, Freshman Honor Society, Alpha Phi Omega service fraternity.

VIA HAND DELIVERY

Dear Ms. Bayo:

In accordance with Chapter 186, Section 186.801 (Ten Year Power Plant Site Plans) of the Florida Statutes, enclosed for filing are twenty-five (25) copies of Florida Power & Light Company's Ten-Year Power Plant Site Plan.

If you have any questions, please do not hesitate to contact me at (305) 552-4332 or Richard Rump at (305) 552-4159.

Sincerely,

Anne Grealy/dc

Overview of The Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten - Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and a disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (FAC).

This Ten - Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) 2000 planning analyses and the forecasted information presented in this plan addresses the 2001 – 2010 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten - year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is data on other FPL resources, including its transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, are presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, as determined in FPL's 2000 IRP work.

Chapter IV – Environmental and Land Use Information

This chapter discusses various environmental information as well as preferred and potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional specific information which is to be included in a Site Plan filing.

Chapter VI – Summary of Required Schedules

This chapter is a contains of Schedules 1 thru 10. It also contains FPL's Ten Year Site Plan Fact Summary.

FPL
List of Abbreviations
Used in FPL Forms

Reference	*Abbreviation*	*Definition*
Unit Type	IC	Internal Combustion
	NP	Nuclear Power
	ST	Steam Unit
	GT	Gas Turbine
	CT	Combustion Turbine
	CC	Combined Cycle
	BIT	Bituminous Coal
Fuel Type	UR	Uranium
	NG	Natural Gas
	FO6	#4,#5,#6 Oil (Heavy)
	FO2	#1, #2 or Kerosene Oil (Distillate)
	BIT	Bituminous Coal
	No	None

	CP	Cooling Pond
Unit/Site Status	P	Planned Unit
	A	Generation Unit Capability Increased (Rerated or Relicensed)

(This page is left intentionally blank)

Executive Summary

Florida Power & Light Company's (FPL) 2001 Ten - Year Power Plant Site Plan (Site Plan) primarily addresses FPL's plans to increase its electric generation capability as part of its efforts to meet its projected incremental resource needs for the 2001 – 2010 time period.

FPL's total generation capability will significantly increase during the 2001 – 2010 time period as is shown in Table ES.1. This table also shows the resulting Summer and Winter reserve margins for FPL over the ten-year time horizon.

Table ES 1 reflects FPL's efforts to repower existing units at its Fort Myers and Sanford sites, its approved DSM goals, planned changes to existing generation units (due to unit overhauls, etc.); and scheduled changes in the delivered amounts of purchased power. The table also reflects the planned additions of new generating units.

The number of these new generating units that will be added is driven in part by the outcome of the Florida Public Service Commission docket No. 981890-EU. This docket ended with a stipulated agreement that primarily resulted in FPL, along with Tampa Electric Company and Florida Power Corporation, switching from a minimum reserve margin planning criterion of 15% to one of 20% beginning with the Summer of 2004. As a consequence, FPL is now planning to add significantly more new generation capacity than was shown in its Site Plans filed prior to this agreement.

As shown in Table ES.1, FPL plans to add four new combustion turbines (CT's) in the 2001 – 2003 time period. Two new CT's will be installed at FPL's existing Martin plant site in 2001. Another two new CT's will be installed at FPL's existing Fort Myers plant site in 2003. All four CT's are projected to be converted into combined cycle (CC) units in 2005 As a result, the pair of new CT's at Martin and the pair of new CT's at Fort Myers will each be converted into one new CC unit. The resulting new CC unit at Martin, and the new CC unit at Fort Myers, will begin operation in 2005.

Also during the 2001 – 2003 time period, FPL will be repowering its two existing steam units at its Fort Myers site and will be repowering two (unit Nos. 4 & 5) of its existing three steam units at its Sanford site.

FPL is also securing capacity for the time period from mid-2001 to mid-2005 through a number of new firm capacity, short-term purchases from utilities and other entities. (Please see Chapter III for a further discussion of these new purchases.)

In addition, eight combined cycle (CC) units will be added during the 2005 – 2010 time period. [1] Two CC units will be added at FPL's Martin plant site, one in 2005 and one in 2006. Another CC unit is projected to be added at FPL's Midway site in 2005. In addition, one new CC unit will be added in 2007 and another in 2009. Finally, three new CC units will be added in 2010 as FPL's UPS contract with Southern Company ends. [2] Sites for the last five CC units for the 2007 – 2010 time frame have not yet been selected.

These planned increases in electric generation capability will allow FPL to continue to maintain system reliability and integrity at a reasonable cost.

[1] FPL's current planning studies have identified new combined cycle units as the generally preferred option to meet future load growth. However, repowering of existing FPL sites remains an alternative to new construction, and FPL will continue to examine this option.

[2] FPL has not yet determined whether it would extend or replace these purchases, or build new capacity to meet its needs. For purposes of this Site Plan it was assumed that the 2010 needs would be met through the addition of unsited CC units. A final decision regarding the 2010 needs is not needed for at least several years.

Projected Capacity Changes and Reserve Margins for FPL [1]					
		Net Capacity Changes (MW)		FPL Reserve Margin (%)	
		Winter [2]	Summer [3]	Winter	Summer

Table E.S. 1

Projected Capacity Changes and Reserve Margins for FPL

Note:

(1) Additional information about these capacity changes and resulting reserve margins is found in Chapter III of this document.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) The initial phase of the Fort Myers repowering project consists of the introduction of operational combustion turbines followed by taking existing steam units out-of-service. The second phase of repowering consists of completing the integration of the combustion turbines, heat recovery steam generators, and steam turbines.

(5) The two CT's at Martin are scheduled to be in-service in the Summer of 2001. Therefore, the CT's are included in the 2001 Summer reserve margin calculation and are included in the 2002 - on reserve margin calculations for Summer and Winter.

(6) These are firm capacity, short - term purchases. See Section I.D. and III.A. for more details.

(7) The initial phase of the Sanford repowering project consists solely of taking existing steam units out-of-service; combustion turbine operation is not introduced at this time. The second phase of the repowering consists of integrating the combustion turbines, heat recovery steam generators, and steam turbines.

(8) The two CT's at Fort Myers are scheduled to be in-service in the Spring of 2003. Therefore, the CT's are included in the 2003 Summer reserve margin calculation and are included in the 2004 - on reserve margin calculations for Summer and Winter.

(9) All combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

10) FPL will be determining at a later date whether to extend or replace these UPS purchases from Southern Company. However, for purposes of this Site Plan, FPL has assumed that the 2010 needs would be met through the addition of unsited combined cyles.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 7.3 million people. FPL served an average of 3,848,401 customer accounts in thirty-five counties during 2000. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility-owned generation, demand side management, and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville. The current generating facilities consist of four nuclear steam units, three coal units, six combined cycle units, twenty-one fossil steam units, forty-eight gas turbines, and five diesel units. The location of these units is shown on Figure I.A.1.

The bulk transmission system is composed of 1,107 circuit miles of 500 Kilovolt (KV) lines (including 75 miles of 500 KV lines [two 37-1/2 mile lines] between Duval Substation and the Florida-Georgia state line, which are jointly owned with Jacksonville Electric Authority) and 2,572 circuit miles of 230 KV lines. The underlying network is composed of 1,614 circuit miles of 138 KV lines, 717 circuit miles of 115 KV lines, and 180 circuit miles of 69 KV transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 497 substations.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3. shows FPL's interconnection ties with other utilities.

Capacity Resources
(as of December 31, 2000)

☐ Non-FPL Territory

	Unit Name	No. of Units	Fuel Type	Summer Megawatts

FPL Interconnection Diagram

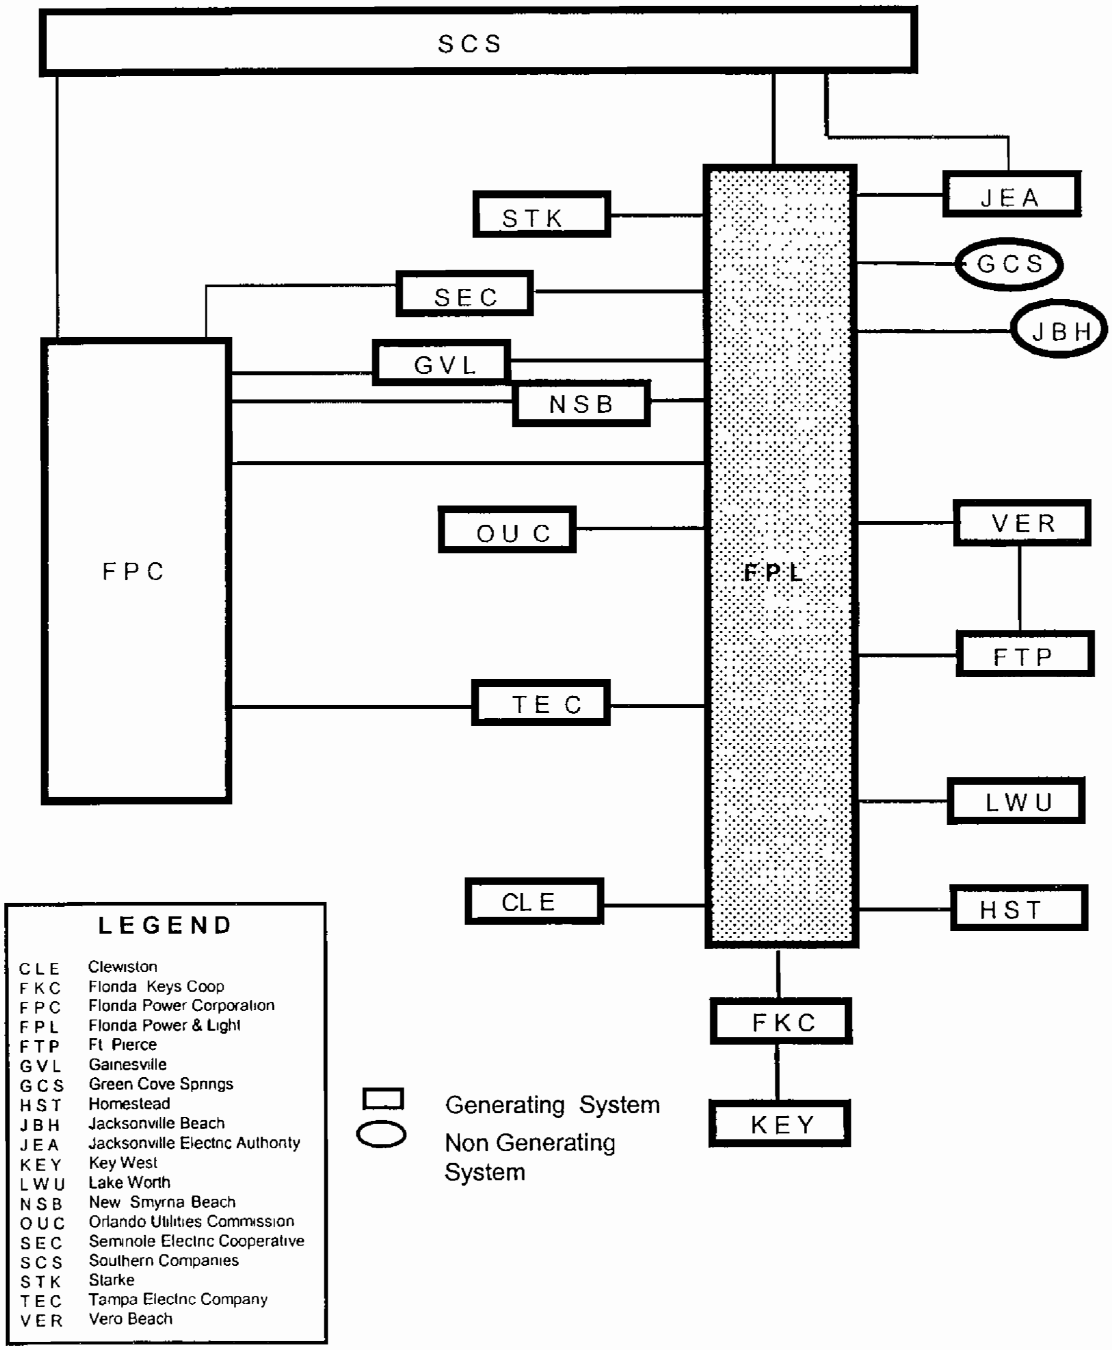

Figure I.A.3

I.B Non-Utility Generation

Non-utility generation is an important part of FPL's resource mix. FPL currently has contracts with eight cogeneration/small power production facilities to purchase firm capacity and energy. A listing of these facilities appears in Table I.B.1. In addition, FPL purchases as-available (non-firm) energy from several cogeneration facilities and small power production facilities as shown in Table I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Florida Power & Light Company Firm Capacity and Energy Contracts with Cogeneration/Small Power Production Facilities

Table I.B.2

I.C. Demand Side Management (DSM)

FPL's DSM activities continue what has been FPL's practice since 1978 of encouraging cost-effective conservation and load management. FPL's DSM efforts through 2000 have resulted in a cumulative Summer peak reduction of approximately 2,680 MW at the meter and an estimated cumulative annual energy saving of 4,830 GWH at the meter.

FPL's current DSM Plan was approved by the Florida Public Service Commission in late 1999 and reflects FPL's new DSM Goals for the 2000 – 2009 time frame. FPL's 2000 resource plan, and the schedule for new generation additions presented in this document, are based on these approved DSM levels.

I.D. Purchased Power

Purchased power remains an important part of FPL's resource mix. FPL has a unit power sales (UPS) contract to purchase up to 931 MW, with a minimum of 380 MW, of coal-fired generation from the Southern Company. In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 382 MW (Summer) and 388 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Unit Nos. 1 and 2 (FPL also has an ownership interest in these units; that ownership amount is reflected in FPL's installed capacity shown on Schedule 1).

Finally, FPL is projecting new firm capacity purchases for the mid - 2001 to mid - 2005 time period. These firm capacity purchases are projected to come from a variety of suppliers. Table I.D.1 presents the Summer and Winter MW resulting from these purchased power contracts through the year 2010.

	FPL's Purchased Power MW (1)

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank)

II. Forecast of Electric Power Demand

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are developed on an annual basis for resource planning work at FPL. These forecasts are a key input to the models used to develop the Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

The primary drivers to develop these forecasts are demographic trends, weather and economic conditions, and prices of electricity and other energy sources. In addition to these drivers, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from NOAA, and inputs from FPL's own customer service planning areas. In the area of demographics, population trends by county, plus housing characteristics such as housing starts, housing size, and vintage of homes, are assessed.

Forecasts for electric usage in the residential and commercial classes include end-use information such as appliance saturation studies, efficiencies, and intensity of energy use. In addition to these inputs, residential forecasts also make use of household characteristics such as ages of members in household, number of members in households, and income distributions.

Several economic forecasting services are contracted to obtain their economic outlook for FPL's service territory. These include Wharton Economic Forecasting Associates (WEFA), Data Resources Incorporated (DRI), and the Bureau of Economic and Business Research (BEBR) of the University of Florida. In addition, FPL actively participates with local development councils and universities to obtain their assessments of the local economy, specifically in the area of expansion of new businesses and retention of the current business base. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

In recent years, the rise of the Tele-communications industry and its potential impact on electric demand has added a new dimension to the forecasting process. Since the needs of the customers in this industry are very project - specific, the customer representatives servicing this class of customers provide insight as to the magnitude and timing of each future project and this information is used in developing the forecast. For example, FPL's 2000 forecast includes an estimate that in 3 years the new load attributed to Tele-communications facilities could reach as much as 570 MW. This additional load in its entirety was treated as a line item adjustment and was added to FPL's 2000 energy and peak forecasts.

II.A. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class for the forecasting period of 2000 – 2019. The results of these sales forecasts are presented in Schedules 2.1 – 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical tool Metrix ND. The methodologies used to develop sales forecasts for each jurisdictional revenue class are outlined below.

1. Residential Sales

Residential energy sales are forecast by multiplying the residential use per customer forecast by the residential customer forecast. Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, Florida per capita income, and Cooling and Heating Degree Days as explanatory variables. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be purchased in greater or lesser quantities depending upon its price. The Cooling & Heating Degree Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric heaters. A composite temperature is derived using hourly temperatures across FPL's service territory (Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained) weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree Days which are based on starting point temperatures of 72°F and 66°F, respectively. The Cooling Degree Days variable is multiplied by the level of air conditioning saturations and the Heating Degree Days variable is multiplied by the level of electric heating saturations. To capture economic conditions the model includes Florida per capita income. The degree of economic prosperity can, and does, affect residential electricity sales.

2. Commercial Sales

The commercial sales forecast is also developed using a regression model. Commercial sales are a function of the following variables: Florida non-agricultural employment, commercial real price of electricity, and Cooling Degree Days. Florida non-agricultural employment is used to capture the economic activity in FPL's service territory. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree Days are used to capture weather-sensitive load in the commercial sector.

3. Industrial Sales

Industrial sales were forecasted through a linear multiple regression model using Florida manufacturing employment and the price of electricity as explanatory variables. Energy sales in this revenue class are primarily due to manufacturers; therefore, employment in this sector is a key variable in capturing the economic activity. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage.

4. Other Public Authority Sales

The sales for this class are developed using an econometric model. Florida manufacturing employment and the other public authority sales of the previous year are used as explanatory variables.

5. Street & Highway Sales and Railroad & Railways Sales

The forecast of Street & Highway sales was developed using a regression model with FPL's total customers and the street and highway sales of the previous period serving as inputs.

The forecasts for Railroads & Railways are held constant since there are no plans for expansion of this economic sector in FPL's service territory.

6. Resales Sales

Resale (Wholesale) customers are composed of municipalities and/or electric cooperatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Contract Rate

Currently there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of the City of Key West, Florida (City of Key West), Metro-Dade County, and FMPA. Sales to the Florida Keys are forecasted using a regression model. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor. Metro-Dade County sells 60 MW to Florida Power Corporation. Line losses are billed to Metro-Dade under a wholesale contract. The forecast is calculated based on assumptions about the magnitude of line losses, the sales monthly capacity factor, and the number of hours in a particular month. FMPA has contracted for delivery of 75 MW for the period of June 2002 through October 2007.

Total Sales

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual Net Energy for Load (NEL).

II.B. Net Energy for Load

An annual econometric model is developed to produce a Net Energy for Load (NEL) forecast. The key inputs to the model are: the price of electricity, Heating & Cooling Degree Days, and Florida Non-Agricultural Employment. Once an annual NEL forecast is obtained using the above-mentioned model, the results are then compared for reasonability to the NEL forecast generated using the total sales forecast. The sales by class are then adjusted to match the NEL from the annual NEL model.

The monthly NEL forecast is also generated for the entire long-term forecasting period of 2000 – 2019. Historical data is used to develop month-to-annual ratios. The ratios are then used to produce the monthly NEL forecast.

The forecasted NEL values for 2001 – 2010 are presented in Schedule 3.3 which appears at the end of this chapter.

II.C. System Peak Forecasts

In recent years, the absolute growth in FPL system load has been associated with a larger customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increasing stock of electricity-consuming appliances), and more efficient heating and cooling appliances. The Peak Forecast models were developed to capture these behavioral relationships.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2001 - 2010 are presented in Schedules 3.1 and 3.2, as well as in Schedules 7.1 and 7.2.

System Summer Peak

The Summer peak forecast is developed using an econometric model. Key variables used in the model include: the total number of FPL Summer customers, the price of electricity, a ratio of Gross Domestic Product (GDP) and Florida Non-Agricultural employment, a dummy variable, and a weather variable. The dummy variable is included to capture the structural change in the economy after the oil crisis in 1975. The weather variable is the product of saturation of air conditioning equipment and maximum Summer temperature.

System Winter Peak

Like the system Summer peak model, this model is also an econometric model. The Winter peak model is a per customer model which consists of three weather-related variables: the minimum temperature on the peak day, a weather term which is a product of heating saturation and minimum Winter day temperature, and Heating Degree Hours for the prior day as well as for the morning of the Winter peak day. In addition, the model also has an economic term which is a ratio of GDP and Florida non-agricultural employment, a dummy variable used to capture the effects of larger homes, and another dummy variable designed to provide additional emphasis for the more recent weather data.

Monthly Peak Forecasts

Monthly peaks for the 2000 - 2019 period are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peak (Summer = April-October, Winter = November-March).

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.D The Hourly Load Forecast

Forecasted values for system hourly load for the period 2000 - 2019 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. These daily load shapes are ranked and used with forecasted monthly peaks, NEL, and calendars in developing an hourly forecast. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

Historical Values (1991 - 2000):

Cols (2) - (4) are actual values for historical summer peaks As such, they incorporate the effects of conservation (Cols. (7&9)), and MAY incorporate the effects of load control IF load control was operated on these peak days Therefore, Col. (2) represents the actual Net Firm Demand
Cols (5) - (9) represent actual DSM capabilities starting from January 1988
Note that the values for FPL's former Interruptible Rate are incorporated into Col (8), which also includes CILC and GS-LC
Col (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak Col (10) is derived by the formula Col (10) =Col. (2) - Col.(6) - Col (8)

Projected Values (2001 - 2010):

Cols (2) - (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control The effects of conservation implemented prior to 2000 are incorporated into the forecast
Cols (5) - (9) represent all incremental conservation and cumulative load control These values are projected August values and are based on projections with a 1/2000 starting point.
Col (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak Col (10) is derived by using the formula Col (10) =Col (2) - Col (5) - Col (6) - Col (7) - Col (8) - Col (9)

Cols. (2) - (4) are actual values for historical winter peaks As such, they incorporate the effects of conservation (Cols (7&9)), and MAY incorporate the effects of load control IF load control was operated on these peak days Therefore, Col. (2) represents the actual Net Firm Demand
Cols. (5) - (9) represent actual DSM capabilities starting from January 1988
Note that the values for FPL's former Interruptible Rate are incorporated into Col (8), which also includes CILC and GS - LC
Col (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak Col (10) is derived by the formula Col (10) = Col (2) - Col.(6) - Col.(8)

Projected Values (2001/02-2009/10):

Cols. (2) - (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control The effects of conservation implemented prior to 1997 are incorporated into the forecast
Cols. (5) - (9) represent all incremental conservation and cumulative load control These values in are projected August values and are based on projections with a 1/2000 starting point
Col (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col (10) is derived by using the formula Col (10) = Col (2) - Col.(5) - Col (6) - Col (7) - Col (8) - Col (9)
Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col (10) is derived by using the formula Col (10) = Col (2) - Col (5) - Col.(6) - Col (7) - Col (8) - Col (9)

Schedule 3.3
History and Forecast of Annual Net Energy for Load - GWH: Base Case

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
Year	Total	Residential Conservation	C/I Conservation	Retail	Wholesale	Utility Use & Losses	Net Energy For Load	Load Factor(%)
1991	73,743	397	186	73,027	716	5,346	73,160	59 1%
1992	73,778	460	221	73,076	702	6,002	73,097	56 9%

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990's and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of potential new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2000 planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs,

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans;

Step 3: Determine the economics for the total utility system with each of the competing options and resource plans; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

Overview of FPL's IRP Process

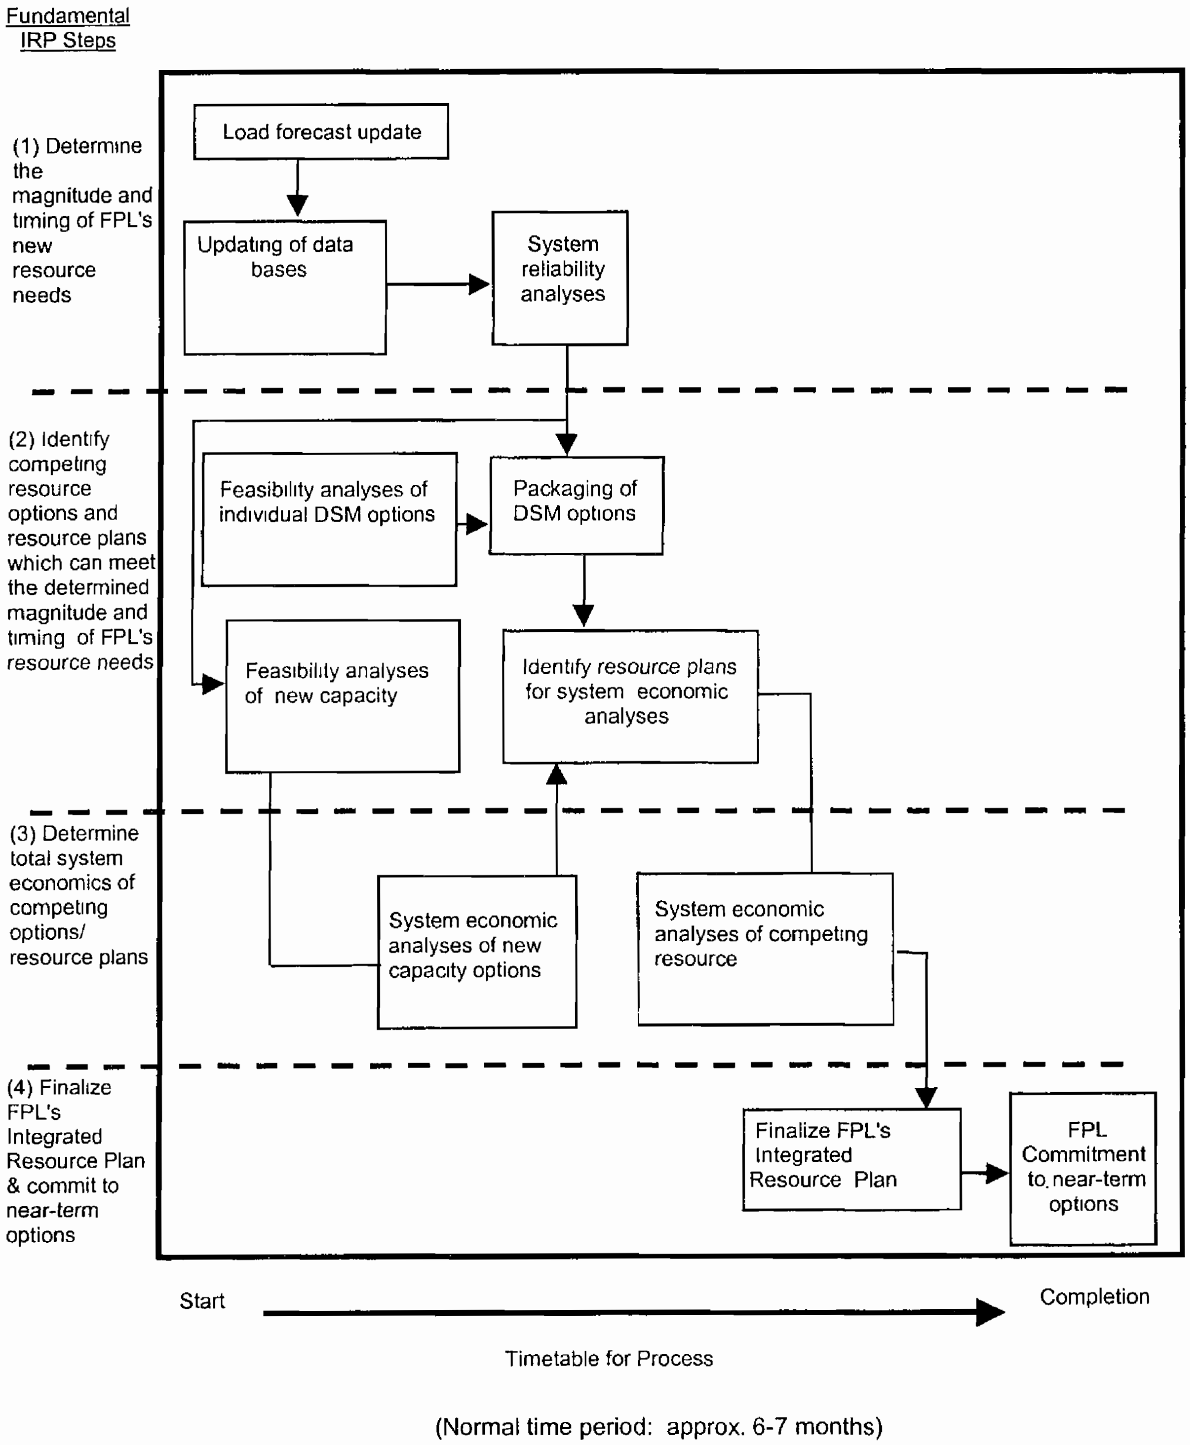

Figure III.A.1

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps – determining the magnitude and timing of FPL's resource needs – is essentially a determination of how many megawatts (MW) of load reduction, new capacity, or a combination of both load reduction and new capacity options are needed. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a reliability analysis for the utility system.

Step 1 starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information which is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. Four assumptions made by FPL during its 2000 IRP work involved near-term construction capacity additions, near-term firm capacity purchase additions, conversion of some of the near-term construction capacity additions from combustion turbine (CT) units to combined cycle (CC) units, and long-term DSM implementation.

The first of these assumptions included FPL's announced plans to add near-term capacity through various construction projects. These construction projects include the repowering of several existing units and the addition of several new CT's. FPL committed in 1998 to repower both existing steam units at its Fort Myers plant site and two of the three existing steam units at its Sanford plant site. These two repowering efforts will add significant capacity to FPL's system and will greatly increase the efficiency of the capacity at those two sites. The repowered Fort Myers capacity is scheduled to come in-service by the Summer, 2002. CT's, which are components of the repowering effort, began coming in-service at Fort Myers in late 2000 and through their initial operation in a stand-alone mode have already increased FPL's system capacity. A somewhat different schedule is planned for the two Sanford units which will be repowered. Both of these units will be repowered without the combustion turbine components coming in-service during the process. Sanford Unit No. 5 will come out-of-service in the Fall, 2001, and return fully repowered by Summer, 2002. Sanford Unit No. 4 will come out-of-service in the Spring, 2002, and return fully repowered at the end of 2002. As a result of this commitment, FPL assumed that these capacity additions resulting from the Fort Myers and Sanford repowerings were a "given" in its 2000 resource planning work.

Another part of FPL's construction capacity addition assumption was its previously announced (in last year's Site Plan) decision to add four new CT's in the 2001 through 2003 time frame. The first two CT's are scheduled to be in-service at FPL's existing Martin site in 2001. The second pair of CT's is scheduled to be in-service in 2003 and will be placed at FPL's existing Fort Myers site. FPL's 2000 resource planning work assumed that these new CT construction capacity additions would also be a "given".

The second of the four assumptions made during the 2000 planning work was that the two CT's at Martin, and the two CT's at Fort Myers, would later be converted into one CC unit at each site. The resulting 2 - CT's – to – 1 - CC conversions at both Martin and Fort Myers are scheduled to be completed by mid-2005. These conversions were also assumed to be a "given" in FPL's 2000 resource planning work.

The third of these assumptions involved a decision which was made during FPL's 2000 resource planning work to secure an amount of capacity for the next few years through firm capacity, short-term purchases. These firm capacity purchases will be from a combination of utility and non-utility generators. These capacity purchases were not all finalized at the time of printing this document[3], but negotiations were sufficiently far along so that FPL projects that the purchases will total approximately 975 MW (Summer) and 1,075 MW (Winter) and will begin in mid-2001 and run to mid-2005. This purchase amount is also assumed as a "given" in FPL's 2000 resource planning work.

The fourth of these assumptions involved DSM. Since 1994, FPL's resource planning work has used the DSM MW called for in FPL's approved DSM goals as a "given" in its analyses. This was again the case in FPL's 2000 planning work as its recently approved new DSM goals through the year 2009 were taken as a given.

[3] Once all of the purchase negotiations are finalized, FPL will inform the Florida Public Service Commission of the details of the purchases including names of selling entities, sizes of purchases, lengths of purchases, etc.

The first place in which these assumptions and much of the other updated information and assumptions are used is the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 15% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 days/year criteria. Both of these criteria are commonly used throughout the utility industry. FPL also used a "third" reliability criterion in its 2000 planning work: a minimum 20% Summer and Winter reserve margin which was applied in the analysis starting in mid-2004 due to a joint settlement reached among FPL, FPC, TECO, and the FPSC in the FPSC's Docket No. 981890-EU.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analyses. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method and this relatively simple calculation can be performed on a spreadsheet. It provides an indication of how well a generating system can meet its native load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as: unit reliability; unit numbers and sizes (i.e., two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time); and the value of being part of an interconnected system.

Therefore, probabilistic methodologies have been used to provide additional information on the reliability of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss-of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does reserve margin analysis.

The end result of the first fundamental step of resource planning is a projection of how many MW are needed to maintain system reliability and of when the MW are needed. This information is used in the second fundamental step: identifying resource options and resource plans which can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans Which Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analyses of new capacity options are carried out to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction / permitting schedules, and operating parameters and costs.

The individual new capacity options are then "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using dynamic programming techniques.

Therefore, at the conclusion of the second fundamental resource planning step in 2000, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs were identified. These resource plans were then compared on an economic basis.

Step 3: Determining the Total System Economics:

At the completion of fundamental Steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for comparing the system economics of these resource plans. FPL combines the resource options into resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI) and Stone & Webster Management

Consultants, Inc. The EGEAS model is also used to perform the economic analyses of the resource plans.

The economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of the competing resource plans is the competing resource plans' impact on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e. a Rate Impact Measure or RIM methodology). However, in cases such as existed for FPL's 2000 planning work in which the DSM contribution was taken as a "given" and the only competing options were new generating units, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, for FPL's 2000 resource planning work, the competing options and plans were evaluated on a present value system revenue requirement basis.

At the conclusion of the analyses carried out in Step 3, a determination of FPL's preferred resource plan was made.

Step 4: Finalizing FPL's 2000 Resource Plan

The results of the previous three fundamental steps' activities were evaluated by FPL management and a decision was made as to what FPL's 2000 resource plan would be. This plan is presented in the following section.

III.B Incremental Resource Additions

FPL's projected incremental generation capacity additions/changes for 2001 through 2010 are depicted in Table III.B.1. (The planned DSM additions are shown separately in Table III.C.1.) These capacity additions/changes will result from a variety of actions including: changes to existing units (which are typically achieved as a result of plant component replacements during major overhauls), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, repowering of existing units, projected construction of new units, and conversion of CT's into CC's.

As shown in Table III.B.1, the bulk of the capacity additions are made up of the following items: the repowering of both existing steam units at FPL's Fort Myers site by Summer, 2002; a similar repowering of FPL's Sanford Unit Nos. 5 and 4 by the Summer, 2002, and the end of 2002, respectively; the construction of four new CT's during the 2001 through 2003 time period followed by their conversion into two CC's in 2005; new firm capacity, short-term purchases in the mid-2001 to mid-2005 time frame; and the construction of eight additional CC units in the 2005 through 2010 time frame.[4]

The increase in the number of CC units which are projected to be built in FPL's 2001 Site Plan, compared to the number of CC units shown in previous Site Plans, is due to three factors. Two of these factors are a higher load forecast and the change from a 15% to a 20% reserve margin criterion.

The third factor is that this year's Site Plan must show for the first time plans for the year 2010. Approximately 930 MW of firm capacity purchases from the Southern Company are scheduled to end in 2010. The end of these purchases requires FPL to replace this capacity, as well as to meet projected load growth for 2010, in a way which meets a minimum 20% reserve margin requirement. While FPL has not yet determined whether it would extend or replace these purchases, or build new capacity to meet its needs, for purposes of this Site Plan it was assumed that the 2010 needs would be met through the addition of unsited CC units. (Note that this is an assumption; FPL may look to extend the purchases or replace them. This decision is not needed for at least several years.)

[4] FPL's current planning studies have identified new combined cycle units as the generally preferred option to meet future load growth. However, repowering of existing FPL sites remains an alternative to new construction, and FPL will continue to examine this option.

Projected Capacity Changes for FPL [1]		Net Capacity Changes (MW)	
		Winter [2]	***Summer*** [3]
2001	Changes to existing plants	8	(56)

Table III.B.1

Projected Capacity Changes for FPL

Note:

(1) Additional information about these capacity changes and resulting reserve margins is found in Chapter III of this document.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) The initial phase of the Fort Myers repowering project consists of the introduction of operational combustion turbines followed by taking existing steam units out-of-service. The second phase of repowering consists of completing the integration of the combustion turbines, heat recovery steam generators, and steam turbines.

(5) The two CT's at Martin are scheduled to be in-service in the Summer of 2001. Therefore, the CT's are included in the 2001 Summer reserve margin calculation and are included in the 2002 - on reserve margin calculations for Summer and Winter.

(6) These are firm capacity, short - term purchases. See Section I.D and III.A. for more details.

(7) The initial phase of the Sanford repowering project consists solely of taking existing steam units out-of-service; combustion turbine operation is not introduced at this time. The second phase of the repowering consists of integrating the combustion turbines, heat recovery steam generators, and steam turbines.

(8) The two CT's at Fort Myers are scheduled to be in-service in the Spring of 2003. Therefore, the CT's are included in the 2003 Summer reserve margin calculation and are included in the 2004 - on reserve margin calculations for Summer and Winter.

(9) All combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

10) FPL will be determining at a later date whether to extend or replace these UPS purchases from Southern Company. However, for purposes of this Site Plan, FPL has assumed that the 2010 needs would be met through the addition of unsited combined cyles.

III.C Demand Side Management (DSM)

1. FPL's Current DSM Programs

FPL's currently approved DSM programs are summarized as follows.

Residential Conservation Service: This is an energy audit program which is designed to assist residential customers in understanding how to make their homes more energy-efficient through the installation of conservation measures/practices.

Residential Building Envelope: This program is designed to encourage the installation of energy-efficient ceiling insulation in residential dwellings that utilize whole-house electric air-conditioning.

Duct System Testing and Repair: This program is designed to encourage demand and energy conservation through the identification of air leaks in whole-house air conditioning duct systems and by the repair of those leaks by qualified contractors.

Residential Air Conditioning: This is a program which is designed to encourage customers to purchase higher efficiency central cooling and heating equipment.

Residential Load Management (On Call): This program offers load control of major appliances/household equipment to residential customers in exchange for monthly electric bill credits.

New Construction (BuildSmart): This program encourages the design and construction of energy-efficient homes that cost-effectively reduce coincident peak demand and energy consumption.

Business Energy Evaluation: This program encourages energy efficiency in both new and existing commercial and industrial facilities by identifying DSM opportunities and providing recommendations to the customer.

Commercial/Industrial Heating, Ventilating, and Air Conditioning: This program is designed to encourage the use of high-efficiency heating, ventilating, and air conditioning (HVAC) systems in commercial/industrial facilities.

Commercial/Industrial Efficient Lighting: This program encourages the installation of energy-efficient lighting measures in commercial/industrial facilities.

Business Custom Incentive: This program encourages commercial/industrial customers to implement unique energy conservation measures or projects not covered by other FPL programs.

Commercial/Industrial Load Control: This program is designed to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits. (This program is closed to new participants in 2000).

Commercial/Industrial Demand Reduction: This program (which starts in 2001) is similar to the Commercial/Industrial Load Control mentioned above by continuing the objective to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits.

Commercial/Industrial Building Envelope: This program encourages the installation of energy-efficient building envelope measures such as window treatments and roof/ceiling insulation for commercial/industrial facilities.

Business On Call: This program offers load control of central air conditioning units to both small, non-demand-billed and medium, demand - billed commercial/industrial customers in exchange for monthly electric bill credits.

2. Research and Development

FPL's DSM Plan continues to support research and development activities. Historically, FPL has performed extensive DSM research and development. FPL will continue such activities not only through its Conservation Research and Development program, but also through individual research projects. These efforts will examine a wide variety of technologies which build on prior FPL research where applicable and will expand the research to new and promising technologies as they emerge.

Conservation Research and Development Program

FPL's Conservation Research and Development Program is designed to evaluate emerging conservation technologies to determine which are worthy of pursuing for program development and approval. FPL has researched a wide variety of technologies and from that research has been able to develop new programs such as Residential New Construction, Commercial/Industrial Building Envelope, and Business On Call.

Cool Communities Research Project

Cool Communities is a concept developed by American Forests to demonstrate the extent to which strategic tree planting and surface color lightening can cool ambient air temperature and impact energy consumption. This research project is designed to evaluate emerging conservation technologies and practices associated with residential structures to determine which are worthy of pursuing for program development and approval. The project, which consists of data gathering, statistical regression analysis, and economic evaluation, will quantify savings from lightened roof color and tree shading of homes.

Commercial/Industrial New Construction Research Project

The objective of this project is to identify cost-effective opportunities in the commercial/industrial new construction market. If cost-effective opportunities are identified, the results of this effort may be used to design a new construction program (and other market intervention strategies) with the ultimate goal being to reduce building demand and energy use beyond that required by the Florida Energy Efficiency Code.

Low Income Weatherization Retrofit Project

This R&D project is investigating cost-effective methods of increasing the energy efficiency of FPL's low - income customers. The research project addresses the needs of low - income housing retrofits by providing monetary incentives to various housing authorities including weatherization agency providers, (WAPS), and non-weatherization agency providers (non-WAPS). These incentives are used by the housing authorities to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting. FPL either conducts a home energy survey, trains housing authority employees to perform FPL home energy surveys, accept the National Energy AudiT (NEAT) (as supplemented to capture water heating recommendations not included in the NEAT audit), or approves similar FPL - approved audits conducted by weatherization providers to determine the need for energy efficient retrofit measures for each home. FPL has designed the project so as to minimize extra work for the retrofit housing authorities.

Photovoltaic Research, Development and Education Project

Photovoltaic (PV) roof-tile systems are a relatively new technology which directly replaces existing roofing materials such as shingles and standing-rib roofing with PV materials. These PV materials have the same water - proofing characteristics as conventional roofing materials. This project is consistent with the Federal Government's Million Solar Roofs initiative. However, based on FPL's research to - date, a primary hurdle to the physical installation of PV systems, whether roofing materials or flat plate collectors, is the lack of awareness, understanding, and acceptance by local building officials. For the most part, these officials are unclear about how these systems work and how to address these systems as part of the building, permitting, and inspection process. This creates barriers toward the use of this technology.

Green Energy Project

FPL has recently finished an R&D project addressing customer acceptance of green energy where donations were used as the funding mechanism for the purchase and installation of utility grid connected PV systems. This project raised in excess of $89,500 and a 10.1 kW (dc) PV system has been constructed at FPL's Martin power plant site.

FPL is now investigating potential customer acceptance of green pricing rates in its Green Energy Project. Under this project, FPL will purchase electric energy generated from new renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable resources. Participating customers will be charged higher "green" electric rates for utilizing electric energy derived from these sources.

Real-Time Pricing

Although not part of FPL's approved DSM Plan, FPL continues to research new conservation/efficiency options such as Real-Time Pricing. This option is an experimental service offering for large C/I customers designed to evaluate customer load response to hourly, marginal cost-based energy prices provided on a day-ahead basis.

3. FPL's DSM MW Goals

FPL's DSM implementation plan is designed to meet currently approved DSM Goals for 2000 – 2009 The combined total residential and commercial/industrial Summer MW reduction values from FPL's DSM Goals for 2000 – 2009 are presented in Table III C.1. FPL has already implemented approximately 2,680 MW at the meter of DSM through 2000.

FPL's Summer MW Reduction Goals for DSM (At the Meter)

Year	Cumulative Summer MW
2000	122
2001	200
2002	269
2003	339
2004	410
2005	484
2006	554
2007	625
2008	697
2009	795

Table III.C.1

III.D Non-Utility Generation Additions

As previously mentioned in Section III.A, FPL is entering into a number of new firm capacity, short-term purchases for the mid-2001 to the mid-2005 time frame. Negotiations for these purchases were not yet completed at the time this document went to print, but some of these purchases are expected to be from non-utility generating facilities. Once all of the purchase negotiations are finalized, FPL will inform the Florida Public Service Commission of the details of the purchases.

Tables I.B.1 and I.B.2 present the previously contracted cogeneration/small power production facilities which are addressed in FPL's resource planning.

III.E Transmission Plan

The 2001 - 2010 transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 KV and 500 KV bulk transmission lines.

List of Proposed Power Lines
2001 – 2010

OWNER	LINE TERMINAL (FROM)	LINE TERMINAL (TO)	NEW CIRCUIT MILES	COMMERCIAL IN-SERVICE DATE (Mo/YR)	NOMINAL OPERATING VOLTAGE (KV)
FPL	Flagami-Turkey Point	Galloway	1.80	Jan-01	230
FPL	Broward-Parkland	Ranch	9.50	Apr-01	230
FPL	Calusa	Fort Myers	1.60	Apr-01	230
FPL	Broward-Corbett	Rainberry	1.75	Jun-01	230
FPL	Greynolds	Laudania	6.70	Jun-01	230
FPL	Poinsett	Sanford	45.00	Jun-01	230
FPL	Poinsett	Sanford	45.00	Jun-01	230
FPL	Fort Myers	Orange River	1.80	Dec-01	230
FPL	Brevard	Malabar	27.00	Jun-02	230
FPL	Broward-Goolsby	Yamato	2.50	Jun-02	230
FPL	Andytwon	Pennsuco	2.00	Jun-03	230
FPL	Broward-Corbett	Yamato	12.50	Jun-03	230
FPL	Cortez	Johnson	11.00	Jun-03	230
FPL	Dade	Overtwon	11.00	Jun-03	230
FPL	Broward-Corbett	Marymount-Yamato	0.25	Jun-03	230
FPL	Yulee	Oneil	6.50	Jun-04	230
FPL	Indiantown	Martin	11.80	Jun-06	230
FPL	Conservation	Levee	36.00	Jun-08	500

Table III.E.1

In addition, there will be transmission facilities needed to connect FPL's projected capacity additions to the system transmission grid. These integrated transmission facilities for the projected capacity additions at FPL's existing Fort Myers, Sanford, Martin, and Midway sites are described below. Since the projected capacity additions for 2007 through 2010 are as-yet unsited, no "integrated" transmission facilities information is provided. This information may be provided in future Site Plan documents once a site is selected.

It should be noted that FPL currently proposes to transfer its transmission facilities to a for - profit transmission company (Grid Florida) which is being formed in response to FERC Order 2000. Once that transfer is completed, FPL will receive transmission service from Grid Florida which will be responsible for transmission planning in the future.

III.E.1 Intregrated Transmission Facilities at Martin

The work required to integrate the incremental capacity projected to be added at Martin from two new CT units with the FPL grid is as follows:

I. Substation:

1. Build one collector bus with 3 breakers each to connect the CT's and the start-up transformer.
2. Add two main step-up transformers (2-200 MVA), one for each CT unit.
3. Add the start-up transformer.
4. Add bus breaker in bay #4 to connect the collector bus in - between this new breaker and breaker 154.
5. Add relays and other protective equipment.

II. Transmission:

1. Construct one string bus to connect the collector and main switchyard.

MARTIN COMBUSTION TURBINES

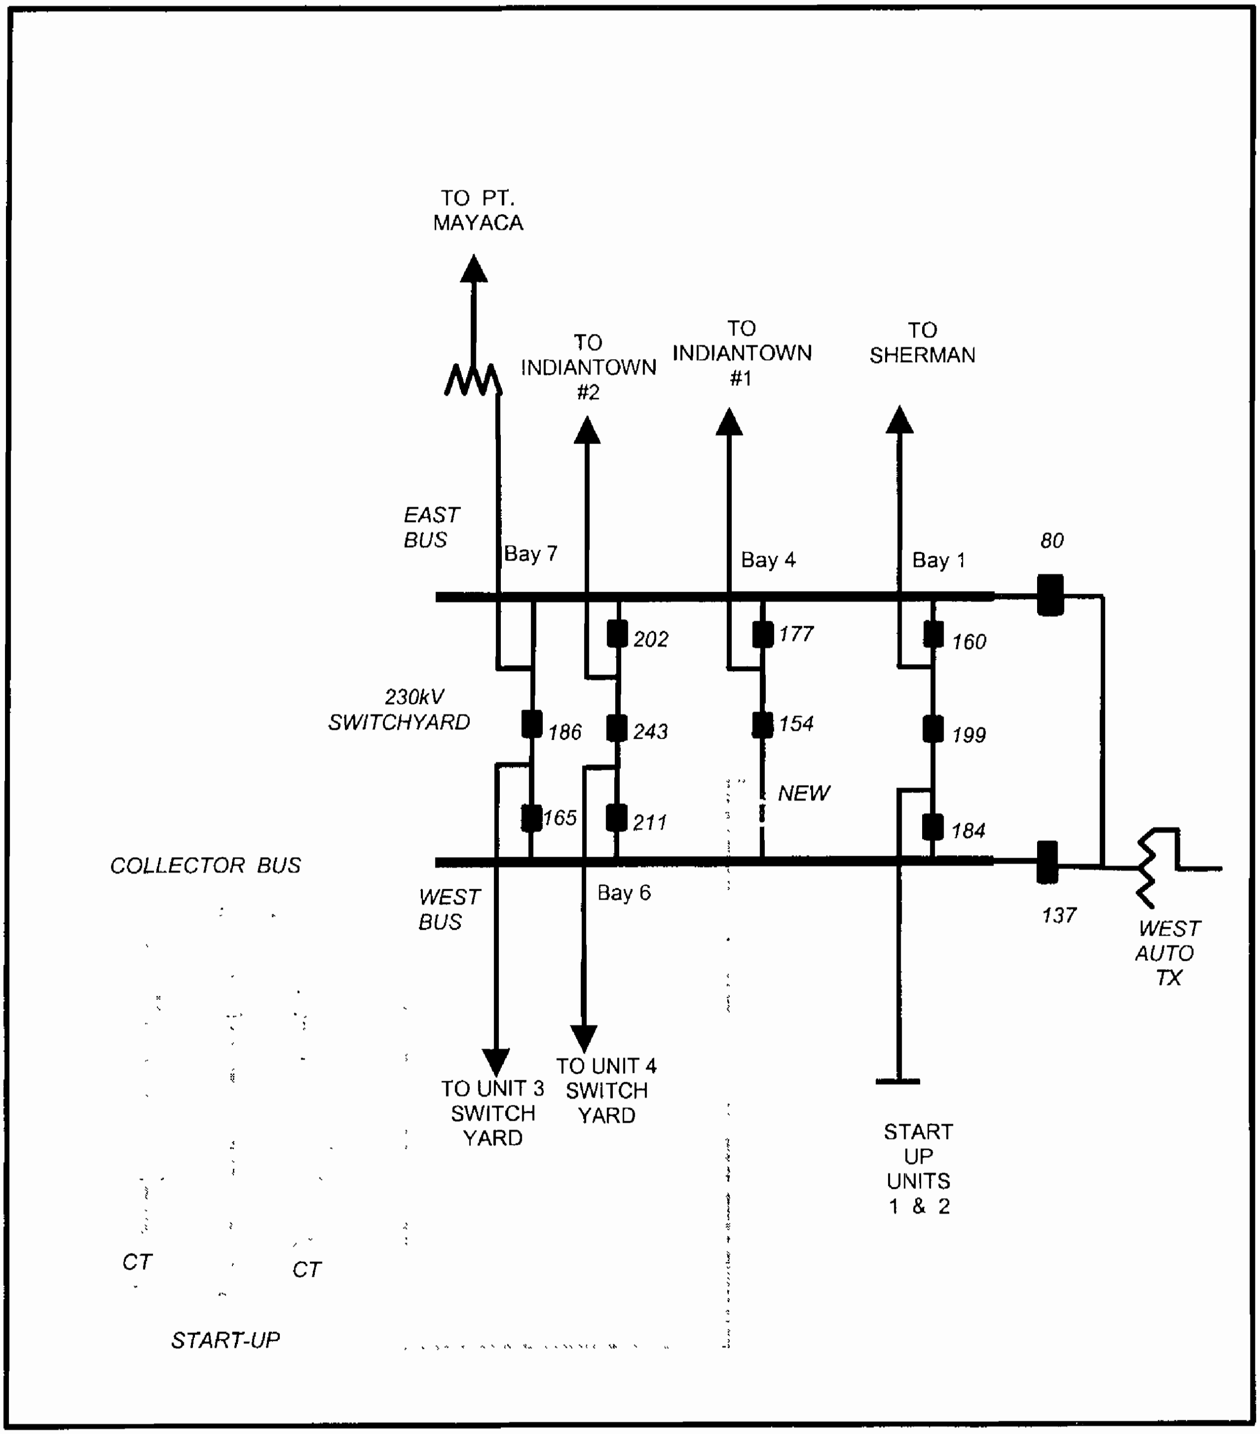

Figure III.E.1

III.E.2 Integrated Transmission Facilities at Fort Myers

The work required to integrate the repowering capacity addition at Fort Myers with the FPL grid is as follows:

I. Substation:

1. Build two collector busses with 3 breakers each to connect 3 CT's on each one. Add another breaker to one of those collector buses to connect the start-up transformer.
2. Add the six main step-up transformers (200MVA/each), one for each CT.
3. Add the start-up transformer.
4. Add a three - breaker bay in the 230 kV substation to connect one of the collector buses and a new transmission line to Calusa.
5. Add a three - breaker bay in the 230 kV substation to connect the other collector bus and a new transmission line to Orange River 230 kV.
6. Add a two - breaker bay at Orange River 230 kV substation to connect the new line from Fort Myers.
7. Add a two - breaker bay at Calusa 230 kV substation to connect the new line from Fort Myers.
8. Replace breakers 3 and 36 (rated 37.6 kA) on bay 9N with new ones rated 63 kA.
9. Add relay and other protective equipment at Fort Myers, Orange River, and Calusa substations.

II. Transmission:

1. Build a new 230 kV line from Fort Myers to Orange River (approximately 2.57 miles) similar to the existing circuits which are bundle 2-1431 ACSR 2580 Amps (1028 MVA) each.
2. Build a new 230 kV line from Fort Myers to Calusa (approximately 1.58 miles) using 1431 ACSR conductor rated 1600 Amps (637 MVA).
3. Add protection and control equipment for the new lines.

FORT MYERS REPOWERING PROJECT

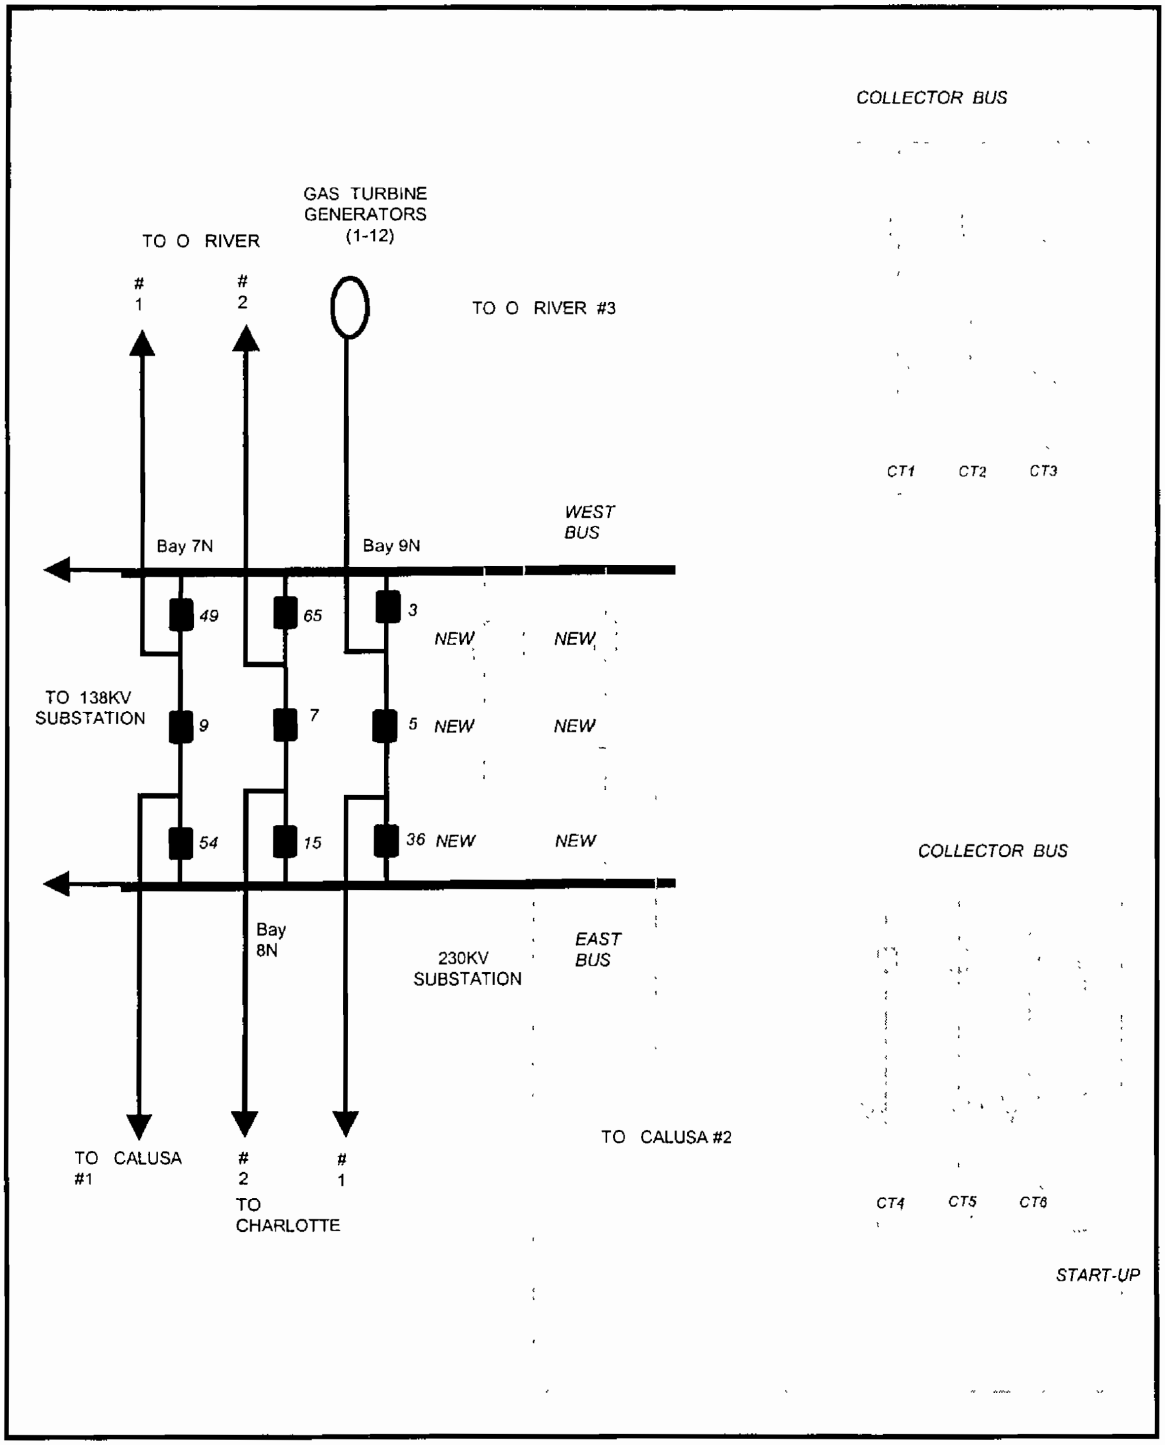

Figure III.E.2

III.E.3 Integrated Transmission Facilities at Sanford

The work required to integrate the repowering capacity additions at Sanford with the FPL grid is as follows:

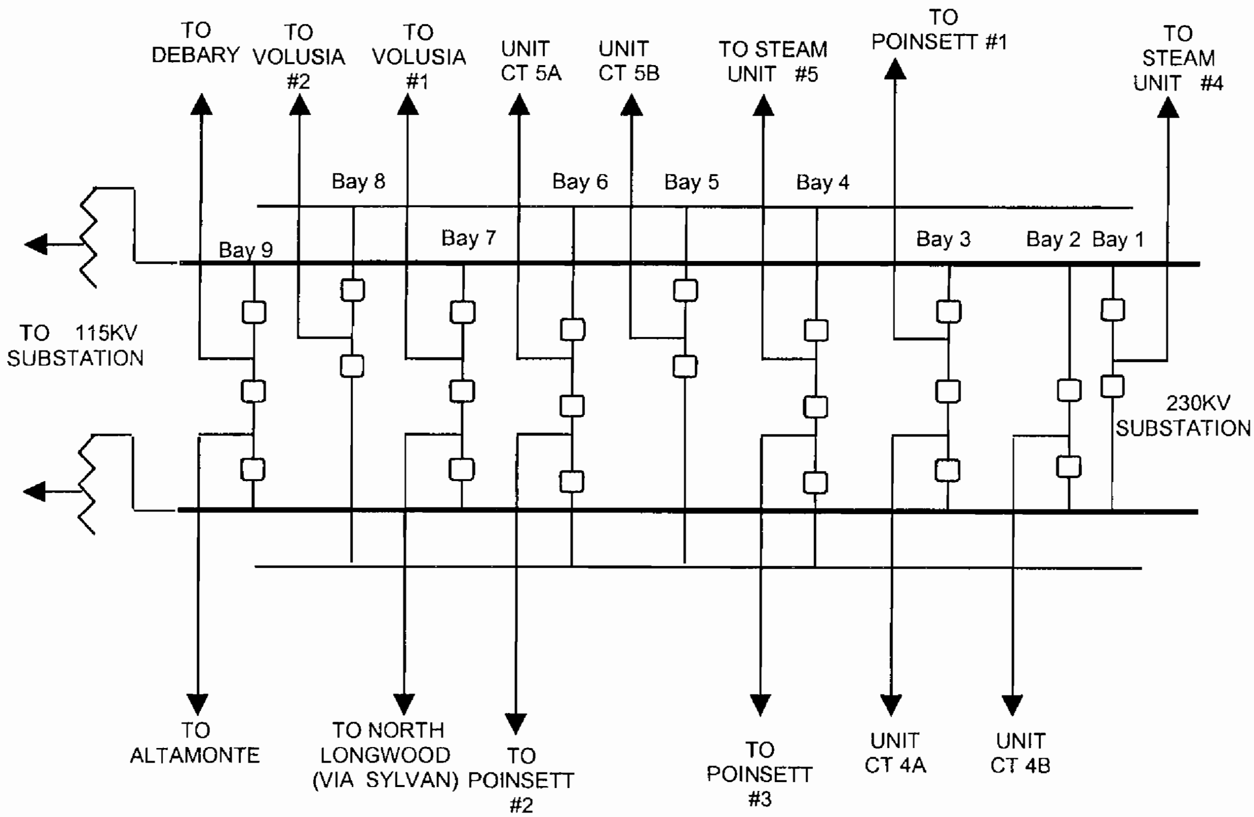
I. Substation:

1. Build four collector buses with 2 breakers each to connect 2 CT's on each one. Add another breaker to one of those collector buses to connect the start-up transformer.
2. Add the eight main step-up transformers (200MVA/each), one for each CT.
3. Add the start-up transformer.
4. Build a new substation with 1 new three - breaker bay, 1 new two - breaker bay, and using 2 existing three - breaker bays to connect 2 collector buses and the new transmission lines.
5. Build 2 new three - breaker bays and 1 new two - breaker bay at the existing substation to connect 2 collector buses.
6. Move the Volusia #2 line terminal from the existing yard to the new 230 KV yard.
7. Add a three - breaker bay at Poinsett 230 kV substation to connect the new lines from Sanford.
8. Add relay and other protective equipment at Sanford and at Poinsett substations.

II. Transmission:

1. Build two new 230 kV lines from the new Sanford to Poinsett (approximately 45 miles each) with conductor rated for 1600 Amps.
2. Add protection and control equipment for the new lines.
3. Upgrade the Volusia #2 transmission line to 1475 Amps.

SANFORD REPOWERING PROJECT



- *SANFORD #4 STEAM AND CT UNITS WILL BE CONNECTED TO THE INSIDE 230KV YARD*
- *SANFORD #5 STEAM AND CT UNITS WILL BE CONNECTED TO THE OUTSIDE 230KV YARD*

Figure III.E.3

III.E.4 Integrated Transmission Facilities at Fort Myers

The work required to integrate the Fort Myers capacity expansion from two new CT units with the FPL grid is as follows:

I. Substation:

1. Build one collector bus with 2 breakers each to connect 2 CT's on each one. Add another breaker to the collector bus to connect the start-up transformer.
2. Add the two main step-up transformers (200MVA/each), one for each CT.
3. Add the start-up transformer.
4. Disconnect the existing Fort Myers GT collector bus from the Fort Myers 230kV switchyard.
5. Add two breakers at Orange River 230 kV substation to connect the new line from the Fort Myers GT collector bus.
6. Connect the new Fort Myers collector bus to the Fort Myers 230kV switchyard.
7. Connect the Fort Myers collector bus to the Fort Myers 230kV switchyard.
8. Replace 4 breakers at the existing Fort Myers 230 kV switchyard.
9. Add relay and other protective equipment at Fort Myers and Orange River substations.

II. Transmission:

1. Build a new 230 kV line from the Fort Myers GT collector bus to Orange River (approximately 2.57 miles) similar to the existing circuits which are bundle 2-1431 ACSR 2580 Amps (1028 MVA) each.
2. Add protection and control equipment for the new line.

FORT MYERS COMBUSTION TURBINES

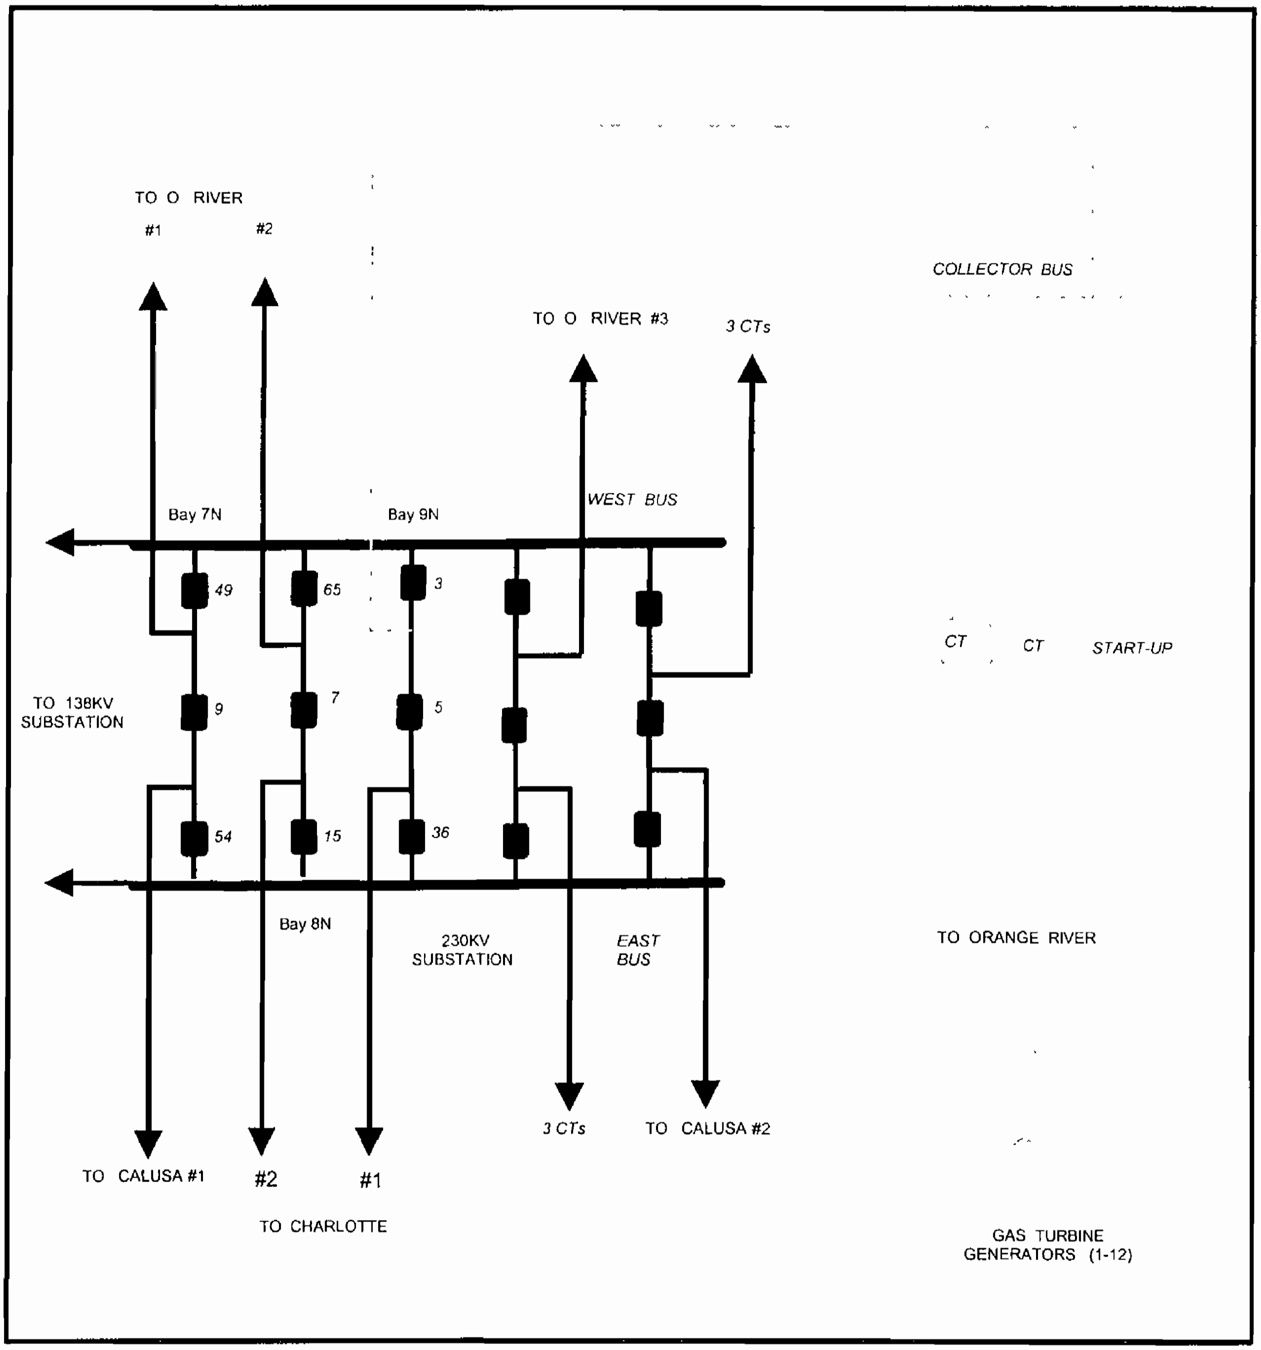


Figure III.E.4

III.E.5 Integrated Transmission Facilities at Martin

The work required to integrate the incremental capacity projected to be added at Martin from two new combined cycle units, Martin Nos. 5 and 6, with the FPL grid is as follows:

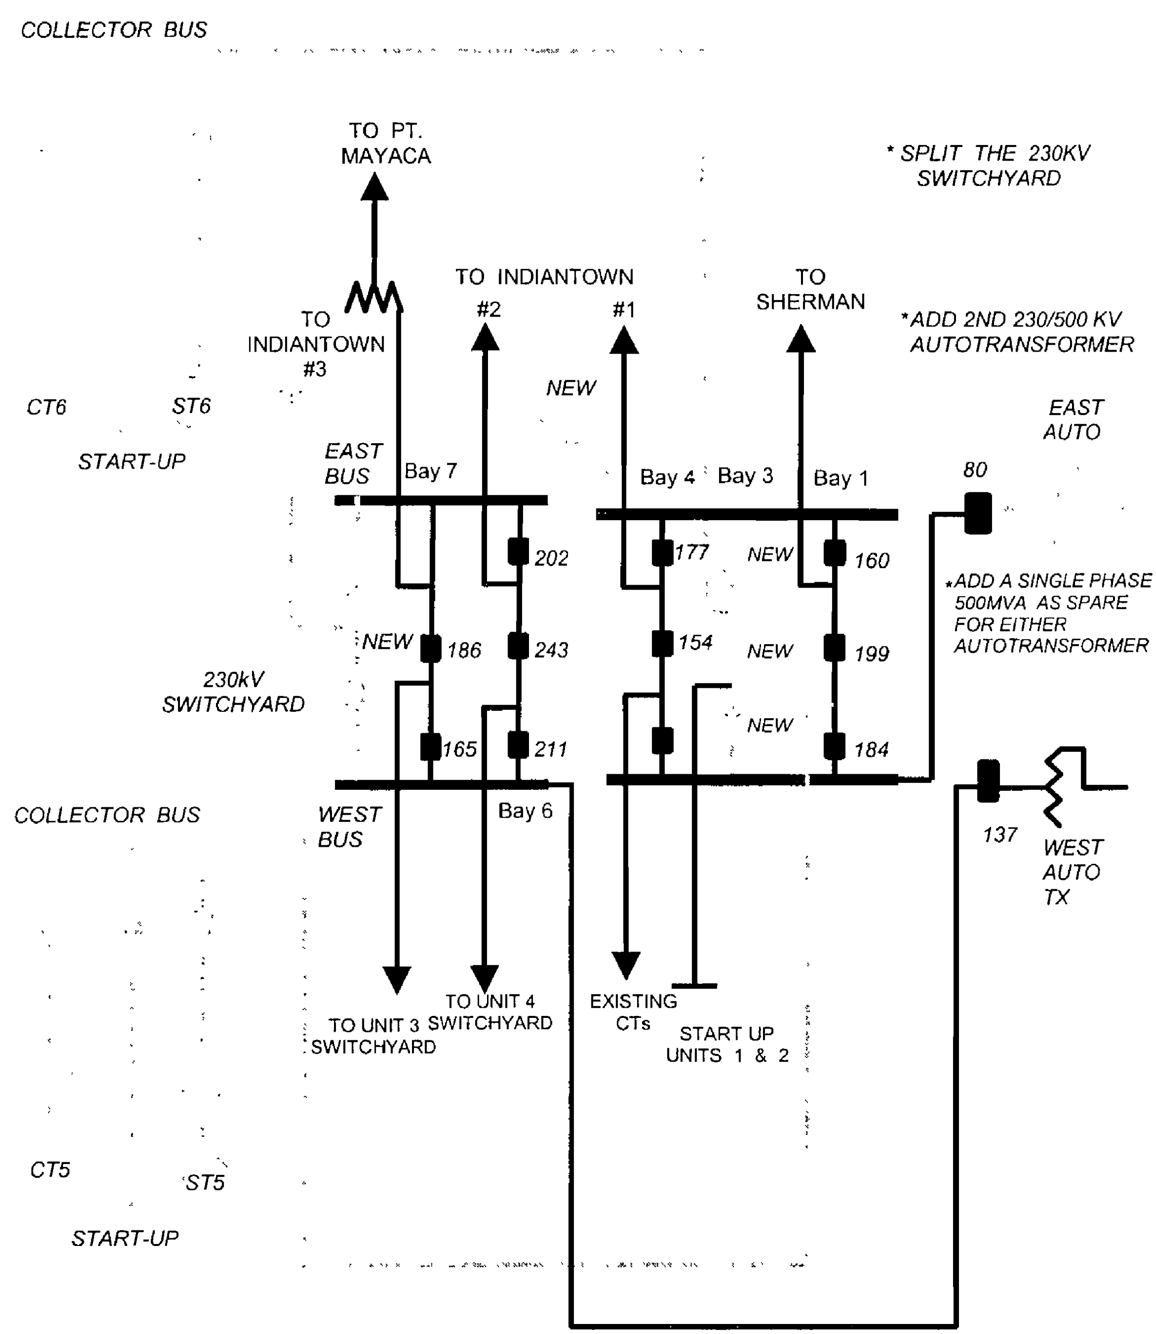
I. Substation:

1. Build two collector busses with 3 breakers each to connect the CT's, the ST units, and the start-up transformers.
2. Add the four main step-up transformers (2-400 MVA and 2-200 MVA), one for each CT and one for each ST unit.
3. Add the start-up transformers.
4. Add a new three-breaker bay (bay #3) to connect the Martin #6 collector bus and the existing start-up for units 1 &2.
5. Connect the Martin #5 collector bus to bay #1 between breakers 199 and 184.
6. Add relays and other protective equipment.
7. Split the 230 kV bus in order to reduce fault current levels in the switchyard. This will effectively separate units 3 and 4 from the new units 5 and 6. The 500/230 kV autotransformer #1 will remain connected to the units 3 and 4 switchyard and the new autotransformer #2 will connect the units 5 and 6 switchyard to the 500 kV bus.
8. Add the second 500/230 kV autotransformer and connect it to breaker 80 and the 230 kV side which is tied to the switchyard for units 5 and 6.
9. Add a single phase 230/500 kV, 500 MVA transformer to be used as a spare for either autotransformer.
10. Add a two-breaker bay (bay 8) to connect the new Martin-Indiantown 230kV line.
11. Add a breaker and line terminal at Indiantown to connect the new Martin-Indiantown 230kV line.
12. Add relays and other protective equipment.

II. Transmission:

1. Construct two string buses to connect the collector and main switchyards.
2. Uprate the Pratt & Whitney-Indiantown 230 kV circuit from 2020 Amps to 2520 Amps.
3. Uprate the Pratt & Whitney-Ranch 230 kV circuit from 2020 Amps to 2520 Amps.
4. Build a new 230kV line from Martin to Indiantown (approximately 11.8 miles) similar to existing circuit which is 2-795B ACSR 2290 Amps (912MVA).

MARTIN COMBINED CYCLE UNITS



* ALSO NEED TO UPRATE THE PRATT & WHITNEY - INDIANTOWN AND PRATT& WHITNEY - RANCH 230KV LINES FROM 2020 AMPS TO 2520 AMPS.

Note. Configuration is subject to modification based on final engineering analysis associated with the Martin area.

Figure III.E.5

III.E.6 Integrated Transmission Facilities at Martin

The work required to integrate the conversion of two existing CT's at Martin add a new steam unit into a combined cycle unit with the FPL grid is as follows:

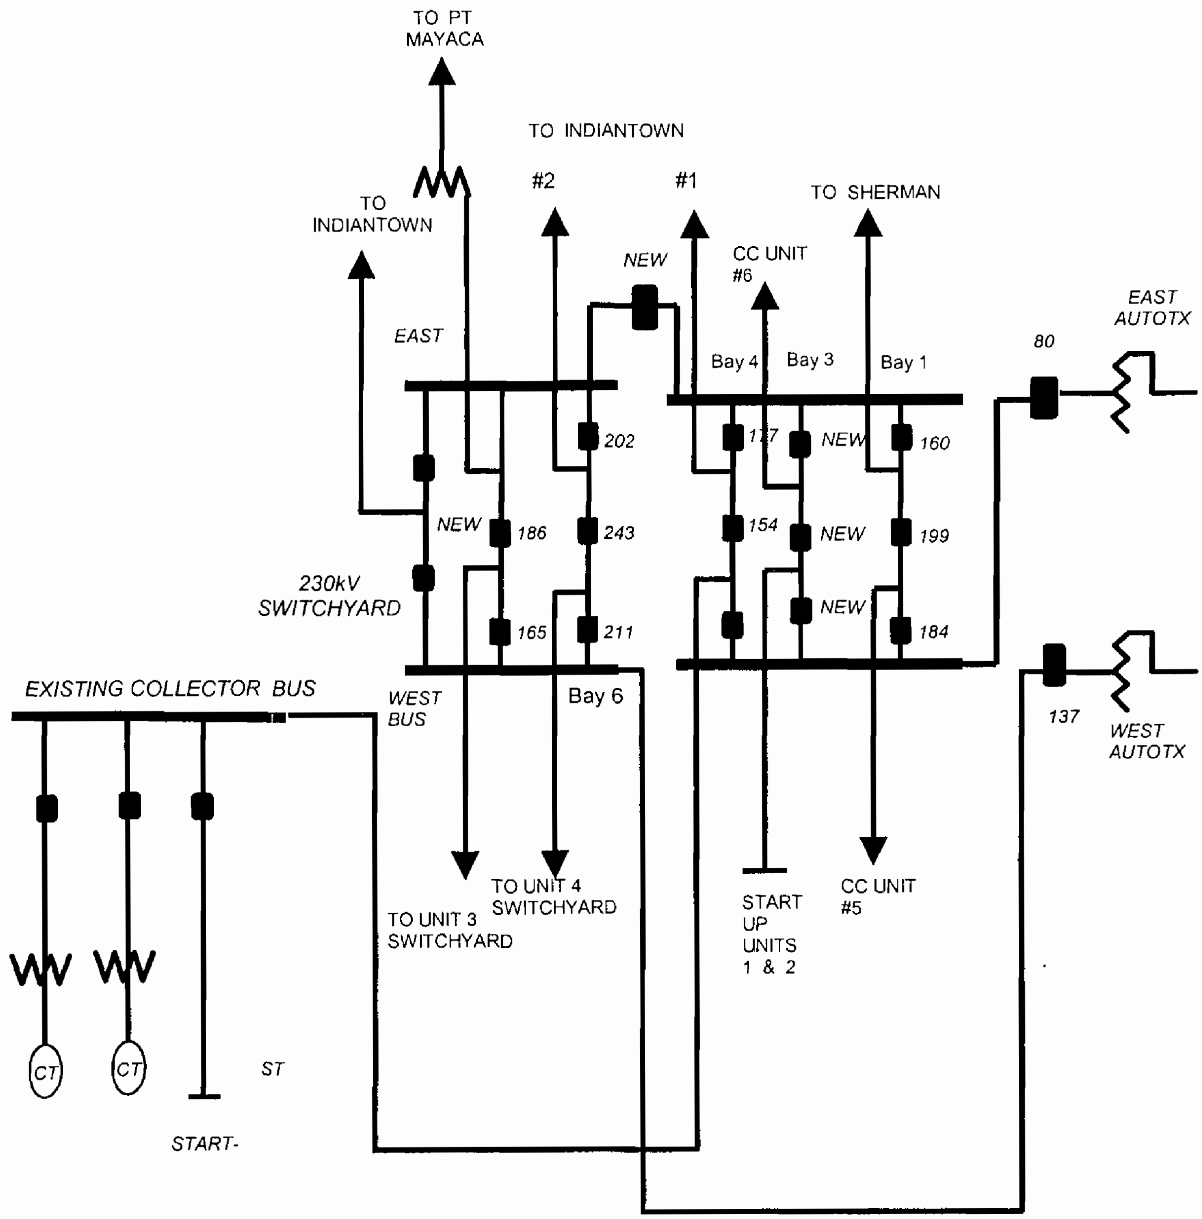
I. Substation:

1. Add one breaker to the collector bus to connect the steam unit step-up transformer (300MVA).
2. Add relay and other protective equipment at the Martin substation.

II. Transmission:

1. None.

MARTIN CONVERSION OF CT'S – TO - CC



Note: Configuration is subject to modification based on final engineering and reliability analysis associated with the Martin area.

Figure III.E.6

III.E.7 Integrated Transmission Facilities at Fort Myers

The work required to integrate the conversion of two existing CT's at Fort Myers into a combined cycle unit with the FPL grid is as follows:

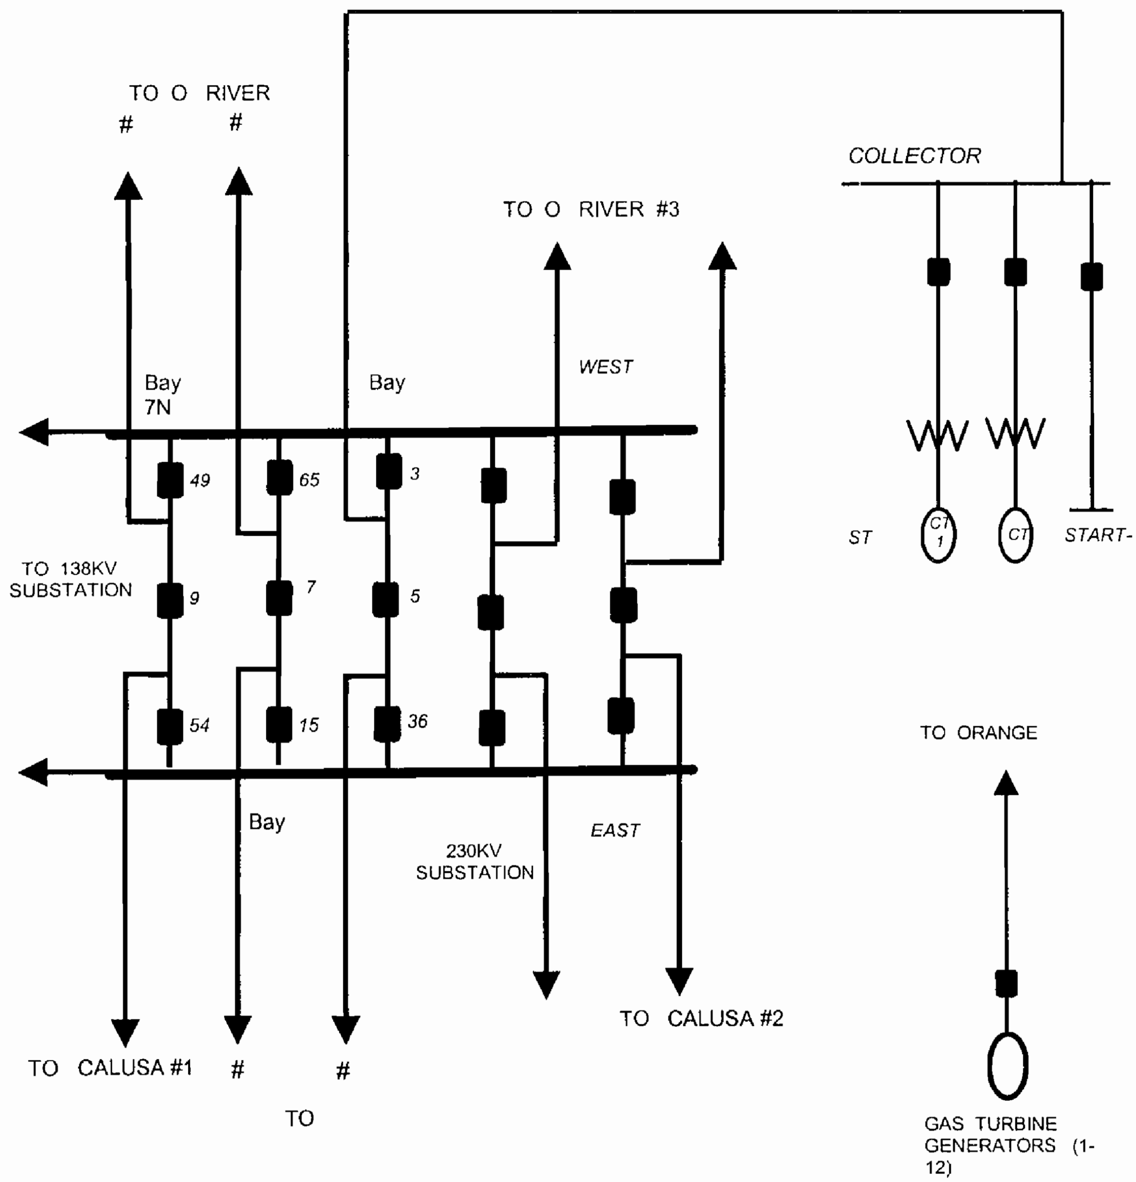
I. Substation:

1. Add one breaker to the collector bus to connect the steam unit step-up transformer (300MVA).
2. Add relay and other protective equipment at the Fort Myers substation.

II. Transmission:

1. None.

FORT MYERS CONVERSION OF CT'S - TO - CC



Note: Configuration is subject to modification based on final engineering and reliability analysis associated with the Ft. Myers area.

Figure III.E.7

II.E.8 Integrated Transmission Facilities at Midway

The work required to integrate the incremental capacity projected to be added at Midway from a new combined cycle unit with the FPL grid is as follows:

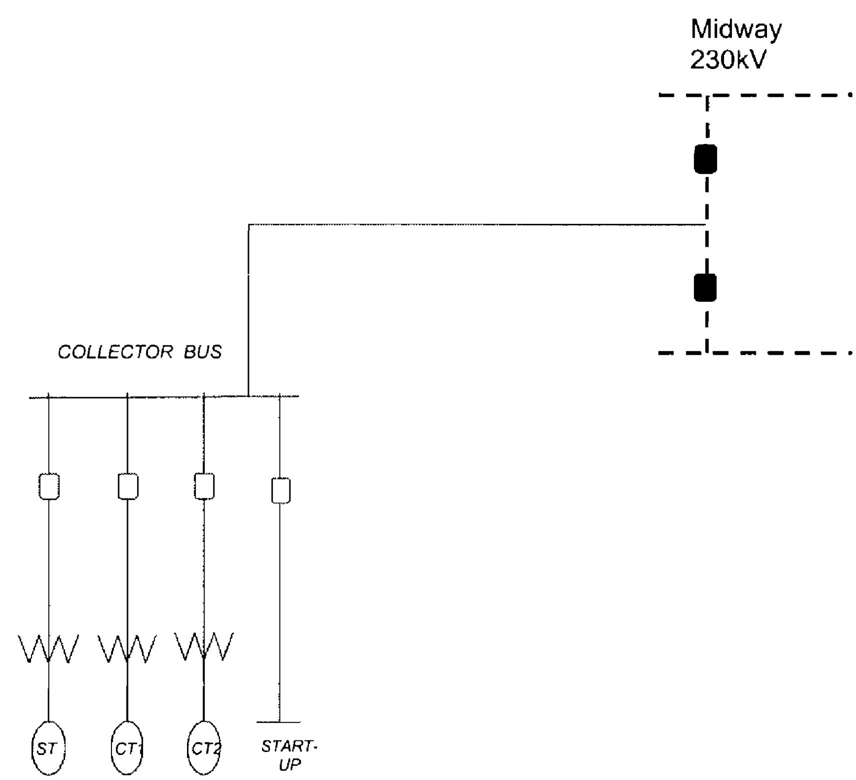
I. Substation:

1. Build one collector bus with 4 breakers to connect the CT's, the ST units, and the start-up transformers.
2. Add the three main step-up transformers (2-225 MVA, 1-300 MVA), one for each CT and one for the ST unit.
3. Add the start-up transformer.
4. Add a new two-breaker bay to connect the Midway collector bus.
5. Add relays and other protective equipment.

II. Transmission:

1. Construct one string bus to connect the collector and the Midway 230kV yard.

MIDWAY COMBINED CYCLE UNIT



Note: Configuration is subject to modification based on final engineering and reliability analysis associated with the Midway area.

Figure III.E.8

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various technologies.

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970's in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities on both a daily and annual basis in Florida. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10 kilowatt (KW) system was placed into operation in 1984. The testing of this PV installation was completed, and the system was removed, in 1990 to make room for substation expansion.

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed on the following page).

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first and only utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was not cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980's, FPL introduced another renewable energy program. FPL's Passive Home Program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. Complete designs and construction blueprints for 6 passive homes were created by 3 Florida architectural firms with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building code. This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test may be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, as well as customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

More recently, FPL has analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach does not require all of its customers to bear PV's high cost, but allows customers who are interested in facilitating the use of renewable energy the means to do so. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund, which FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid. Thus, when sunlight is available at this site(s), the PV-generated electricity displaces an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach, which has been termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's initial effort to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL initiated the effort in 1998 and received approximately $89,000 in contributions which significantly exceeded the goal of $70,000. FPL has purchased the PV modules and installed them at FPL's Martin plant site.

As previously discussed, FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was the Green Energy Project which is a second, different attempt to implement the basic Green Pricing approach. Under this project FPL will purchase electric energy generated from new renewable resources. The project offers to meet all, or part of, a customer's load with generation from new renewable resources, with the remaining portion of that load being served by the Company's conventional generating facilities.

Participants will be residential (and possibly commercial) customers who will pay higher ("green" rates) for electricity provided from these renewable sources.

The second effort initiated in 2000 is FPL's Photovoltaic Research, Development and Education Project. This demonstration project's objectives are to increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks as well as the energy capabilities of roof tile PV systems, and assess the homeowner's financial benefits and costs of PV roof tile systems.

Finally, FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy, and as-available energy, have been purchased by FPL from these developers. (Please refer to Tables I.B.1 and I.B.2).

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980's, FPL relied primarily on a combination of oil, natural gas, and nuclear energy to generate electricity. In 1986, coal was first added to the fuel mix, allowing FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources have been added with the acquisition (76%) of Scherer Unit # 4. In 1997, petroleum coke was added to the fuel mix as a blend stock with coal at the St. Johns River Power Park.

2. Fuel Price Forecasts

FPL's long-term oil price forecast assumes that worldwide demand for petroleum products will grow moderately throughout the planning horizon. Non-OPEC crude oil supply is projected to increase as new and improved drilling technology and seismic information will reduce the cost of producing crude oil and increase both recovery from existing fields and new discoveries. However, the rate of increase in non-OPEC supply is projected to be slower than that of petroleum demand, resulting in an increase in OPEC's market share throughout the planning horizon. As OPEC gains market share, prices for petroleum products are projected to increase.

FPL's natural gas price forecast assumes that domestic demand for natural gas will grow throughout the planning horizon, primarily due to increased requirements for electric generation. Domestic natural gas production will increase as new and improved drilling technology and seismic information will reduce the cost of finding, developing, and producing natural gas fields. The rate of increase in domestic natural gas production is assumed to be slower than that of demand, with the balance being supplied by increased Canadian and liquefied natural gas (LNG) imports. As demand for natural gas in Florida grows, it is anticipated that based on natural gas users' commitments, the Florida Gas Transmission pipeline system will be augmented/expanded and/or a new pipeline will be constructed to meet the growth in demand.

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated All values are Summer net MW

2/ Firm Capacity Imports include all firm capacity purhcases whether from out - of - state or in - state

3/ Total Capacity Available=Col (2) + Col (3) - Col (4) + Col (5)

4/ These forecasted values reflect the Most Likely forecast without DSM

5/ The MW shown represent cumulative load management capability plus incremental conservation from 1/99 - on They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based

6/ Margin (%) Before Maintenance = Col (10)/Col (9)

7/ Margin (%) After Maintenance =Col (13) /Col (9)

1)The Winter Total MW value consists of all generation additions and changes achieved by January The Summer Total MW value consists of all generation additions and changes achieved by July All other MW will be picked up in the following year This is done for reserve margin calculation

2) All MW differences are calculated based on using IRP 2000 Submittal (for the year 2000) as the base for all other years

3) Negative values for Sanford and Ft Myers reflect the existing steam units being temporarily out of service during that seasonal period for repowering efforts

1)The Winter Total MW value consists of all generation additions and changes achieved by January The Summer Total MW value consists of all generation additions and changes achieved by July All other MW will be picked up in the following year This is done for reserve margin calculation

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1)	**Plant Name and Unit Number:**	Martin Combustion Turbines No. 8A and No. 8B *	
(2)	**Capacity**		
	a Summer	149	MW
	b. Winter	181	MW
(3)	**Technology Type:**	Combustion Turbine	
(4)	**Anticipated Construction Timing**		
	a. Field construction start-date:	1999	
	b. Commercial In-service date:	2001	
(5)	**Fuel**		
	a. Primary Fuel	Natural Gas	
	b. Alternate Fuel	Distillate	
(6)	**Air Pollution and Control Strategy:**	Dry Low Nox Combustors, Natural Gas, 0 05% S. Distillate, & Water Injection on Distillate	
(7)	**Cooling Method:**	Air Coolers	
(8)	**Total Site Area:**	11,300	Acres
(9)	**Construction Status:**	P	(Planned)
(10)	**Certification Status:**	P	(Planned)
(11)	**Status with Federal Agencies:**	P	(Planned)
(12)	**Projected Unit Performance Data:**		
	Planned Outage Factor (POF):	1%	
	Forced Outage Factor (FOF):	1%	
	Equivalent Availability Factor (EAF):	98%	
	Resulting Capacity Factor (%):	Approx. 10%	(First Year)
	Average Net Operating Heat Rate (ANHOR):	10,430	Btu/kWh
(13)	**Projected Unit Financial Data **,*****		
	Book Life (Years):	25	years
	Total Installed Cost (In-Service Year $/kW):	477.98	
	Direct Construction Cost ($/kW):	449.20	
	AFUDC Amount ($/kW):	29.30	
	Escalation ($/kW):	-0.53	
	Fixed O&M ($/kW -Yr.):	0.68	
	Variable O&M ($/MWH):	0.86	
	K Factor:	1.5134	

* Values shown are per unit values for the two units being added.
** $/KW values are based on Summer capacity.
*** Fixed O&M includes capital replacement.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1)	**Plant Name and Unit Number:**	Fort Myers Repowering	
(2)	**Capacity**		
	a. Summer	929	MW Incremental (1473 MW Total After Repowering)
	b. Winter	1,073	MW Incremental (1617 MW Total After Repowering)
(3)	**Technology Type:**	Combined Cycle	
(4)	**Anticipated Construction Timing**		
	a Field construction start-date:	2000	
	b. Commercial In-service date:	2002	
(5)	**Fuel**		
	a. Primary Fuel	Natural Gas	
	b. Alternate Fuel	None	
(6)	**Air Pollution and Control Strategy:**	Dry Low Nox Combustors, Natural Gas	
(7)	**Cooling Method:**	Once-through Cooling	
(8)	**Total Site Area:**	460	Acres
(9)	**Construction Status:**	P	(Planned)
(10)	**Certification Status:**	P	(Planned)
(11)	**Status with Federal Agencies:**	P	(Planned)
(12)	**Projected Unit Performance Data:**		
	Planned Outage Factor (POF):	3%	
	Forced Outage Factor (FOF):	1%	
	Equivalent Availability Factor (EAF):	96%	
	Resulting Capacity Factor (%):	96%	(First Year)
	Average Net Operating Heat Rate (ANHOR):	6,830	Btu/kWh
(13)	**Projected Unit Financial Data, *,**,*** **		
	Book Life (Years):	25	years
	Total Installed Cost (In-Service Year $/kW):	655.96	
	Direct Construction Cost ($/kW):	560.71	
	AFUDC Amount ($/kW):	94.59	
	Escalation ($/kW):	0.66	
	Fixed O&M ($/kW -Yr.):	13.30	
	Variable O&M ($/MWH):	0.37	
	K Factor:	1.5419	

* $/kW values are based on incremental Summer capacity.
** Note that cost values shown do not reflect the FPL system benefits which result from efficiency improvements to the existing steam capacity at the site.
*** Fixed O&M includes capital replacement.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1)	**Plant Name and Unit Number:**	Sanford Unit 4 Repowering	
(2)	**Capacity**		
	a. Summer	567	MW Incremental (957 MW Total After Repowering)
	b. Winter	671	MW Incremental (1065 MW Total After Repowering)
(3)	**Technology Type:**	Combined Cycle	
(4)	**Anticipated Construction Timing**		
	a. Field construction start-date:	2000

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in our service area is continuing, which heightens competition for air, land, and water resources which are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

Over the years FPL has gained national recognition for its commitment to meeting its customers' energy needs in harmony with the environment. For example, in 1983, FPL won the U.S. Department of the Interior's Conservation Service Award and received the Florida Audubon Society's Corporate Service Award in 1986. In 1998, FPL won the U.S. Coast Guard's prestigious William M. Benkert Award for demonstrating "tremendous vision and dedication to excellence in marine environmental protection." FPL's environmental protection commitment is an integral part of how it conducts business and formal corporate policies have been established to protect the environment.

In March, 2000, Innovest, a company that evaluates environmental performance of Fortune 500 companies, ranked FPL number one of 30 electric utilities reviewed. The Innovest report relates environmental performance with overall management performance and suggests that good environmental performance is a predictor of good investment opportunity.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define the Company's position. This statement reflects how FPL incorporates environmental values into all aspects of the Company's activities and serves as a framework for new environmental initiatives throughout the Company. The FPL environmental statement further establishes a long-term direction of environmental responsibility for the Company. FPL's Environmental Statement is:

It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:

- Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
- Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
- Encourage the wise use of energy to minimize the impact on the environment.
- Communicate effectively on environmental issues.
- Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program which is discussed below. Other components include: written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident/emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to: evaluate environmental performance, verify compliance with Company policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to: 1) facilitates management control of environmental practices; and, 2) assess compliance with existing environmental regulatory requirements and Company policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and public education. Some of FPL's 2000 environmental outreach activities are noted in Table IV.E.1.

2000 FPL Environmental Outreach Activities

Site	Activity	# of Participants (approx.)
St. Lucie Plant	Turtle Beach Nature Trail Visitation	2,020
Riviera Plant & Fort Myers Plant	Manatee Awareness Activities	144,000
St. Lucie Plant	Turtle Walk Participation	725
St. Lucie Plant	FPL Energy Encounter	32,974
Not Applicable	Inquiries – 800 environmental information line and emails	4,500
Martin Plant	Barley Barber Swamp Visitation	3,400

Table IV.E.1

IV.F Preferred And Potential Sites

Based upon its projection of future resource needs, FPL has identified preferred and potential sites for future generation additions. These preferred and potential sites are discussed in separate sections below.

IV.F.1 Preferred Sites

FPL has identified four preferred sites: the existing Fort Myers plant site, the existing Sanford plant site, the existing Martin plant site and the existing Midway substation site, These four sites are currently the expected known locations for the capacity additions, which FPL projects to make during the 2001 – 2006 period. (Other capacity additions, in the form of new combined cycle units, will be made in the 2007 through 2010 time period. Selection of sites for these later capacity additions is not yet needed and has not been made. Please see Table III.B.1).

The four preferred sites are discussed below. FPL has committed to repower existing units at both its Fort Myers and Sanford sites, to first add new combustion turbine (CT), then later convert this CT capacity into combined cycle (CC) capacity at the Martin and Fort Myers sites, and to add new combined cycle (CC) capacity at the Martin and Midway sites.

Preferred Site #1: Fort Myers Plant, Lee County

The site is located on the 460-acre Fort Myers property. Current facilities on the site include two steam electric generating units (nominally 150 MW and 400 MW, respectively), three CT's (which will soon be joined by three more CT's) which, along with heat recovery steam generating (HRSG) units and the existing steam turbines will comprise the repowered facility (construction completion in 2002); and a bank of 12 simple-cycle combustion turbine peaking units. The site has direct access to a four-lane highway, State Road (SR) 80, and barge access is available. The nearest town is Tice, which is approximately 4 miles west of the site. The City of Fort Myers is approximately 8 miles west of the site. The Fort Myers site has been listed as a potential or preferred site in previous FPL Site Plans.

FPL is planning to add new capacity by first adding two CT's, then converting the two CT's into one CC unit. The CT's are expected to be in service in the Spring of 2003 and will add 298 MW (Summer) and 362 MW (Winter) to FPL's system. The conversion to CC configuration is planned to be completed and in - service by mid-2005. The CT – to – CC conversion will add approximately another 249 MW (Summer) and 234 MW (Winter) to FPL's system.

The repowering project currently underway at the site will add approximately 930 MW during Summer conditions and approximately 1,070 MW during Winter conditions. This project is expected to be completed in mid-2002.

The output capability of the existing bank of 12 CT's at the site will be unaffected by the repowering project and the addition of the two new CT's.

a. and b. U.S. geological Survey (USGS) May and Proposed Facilities Layout Map

A USGS map of the Fort Myers plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter. It is pertinent to note that several designations on the current South Florida Water Management District Florida Land Use, Cover, and Forms Classification System (FLUCCS) appear to be in error, or to require some clarification. For example, the freshwater marsh identified toward the western boundary of the site is actually FPL's 50-acre evaporation/percolation pond. Similarly, while there are scattered mangroves along the shore, the "Central Mangrove" area shown is not mangrove but is the FPL switchyard for that site. The "Improved Pasture" shown towards the east of the site is currently the location of a tree nursery.

d. Existing Land Uses of Site and Adjacent Areas

The land on the site is primarily dedicated to industrial use with surrounding grassy and landscaped areas. There is the previously mentioned 50-acre evaporation/percolation pond on the site. Much of the site is currently being used for either direct construction activities or in support of the repowering project.

FPL has recently donated an 18-acre island, located north of the plant in the Caloosahatchee River, to the United States Fish & Wildlife Service (USFWS) for the purpose of wildlife conservation. This island has been owned by FPL since the 1950's, but has never been developed. The USFWS plans to incorporate the island into the Caloosahatchee National Wildlife Refuge.

Lee County operates Manatee Park (approximately 5 acres) with a manatee viewing area on FPL property to the east side of the discharge canal where it adjoins the Orange River south of SR 80. This manatee viewing area provides public viewing and education about the species. FPL leases the property to the county for a nominal amount.

The adjacent land uses are light commercial and retail to the south of the property and some residential areas located toward the west. Mixed scrub with some hardwoods and wetlands, plus agriculture land, can be found to the east and further to the south. The Caloosahatchee National Wildlife Refuge is located across the Caloosahatchee River, northwest of the power plant.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

The site is adjacent to the south bank of the Caloosahatchee River near the confluence of the Orange River and the Caloosahatchee. Much of the site is no longer in its original natural condition. However, a scattering of mangroves can be found along the river shoreline. Some mixed scrub with some hardwoods and wetlands can be found to the east and further to the south. Other than the occasional congregation of manatees noted below, FPL is not aware of any significant environmental features on the site or in the vicinity.

2. Listed Species

Construction and operation of the repowered facility, plus the new CT's/CC at the site, are not expected to affect any rare, endangered, or threatened species. The only known listed species associated with the site are the West Indian Manatees (Trichechus manatus: Federal - and - State listed as Endangered) which are attracted to the warmed waters in the vicinity of the site discharge and can be found congregating in the area during cool weather.

The Florida Natural Areas Inventory (FNAI) reports the presence of the Eastern Indigo Snake (Drymarchons corais couperi: Federal - and - State listed as Threatened) and Tricolored Heron (Egretta tricolor: State - listed as a Species of Special Concern) within a two-mile radius of the site.

3. Natural Resources of Regional Significance Status

No Natural Resource of Regional Significance is identified on the plant site in the Southwest Florida Regional Strategic Policy Plan.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design options currently being pursued for the Fort Myers site are the repowering of the two existing oil-fired boilers with natural gas-fired CT's and HRSG's, plus the installation of two stand-alone CT's. As previously mentioned, these two CT's will later be converted into one CC unit. All of this new generation equipment will be installed on the existing facility property and will make effective use of existing transmission facilities and infrastructure although some transmission line upgrades will be required. Steam developed in the new HRSG's will be directed to the existing steam turbines. FPL has contracted with Florida Gas Transmission (FGT) for a firm natural gas supply to the plant.

Mitigation options being planned for the capacity additions at Fort Myers include: the capture and reuse of plant process water, the use of combustion technology that is inherently low in air pollutant emissions, the reduction or cessation of heavy oil barge traffic on the Caloosahatchee River, plumbing the sanition system to Lee County's system and closing the on-site septic tanks, and closing the on-site ash basins.

Six CT's are being installed at the site in support of the repowering project. Several of these CT's are now operational in simple-cycle mode. Conversion to combined-cycle mode to complete the repowering process will occur during mid-2002.

g. Local Government Future Land Use Designations

The Local Government Future Land Use Plan designates the major portion of the site as Public Facilities and a small area as Resource Protection. Since there are no significant environmental resources on the site, and the "Resource Protection" designated area appears to be the location of a current tree nursery, FPL believes that this designation is in error.

h. Site Selection Criteria and Process

For the past several years, many of FPL's existing power plant sites have been considered potentially suitable sites for new, expanded, or repowered generation. The Fort Myers plant has been selected as a preferred site due to a combination of electrical transmission and system load factors, plus economic considerations. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered permittable.

i. Water Resources

The available surface water source is the Caloosahatchee River and the available groundwater source is the shallow aquifer.

j. Geological Features of Site and Adjacent Areas

The geology underlying the Fort Myers Plant consists of Quaternary Holocene and Pleistocene undifferentiated materials. The upper part of these undifferentiated materials consists of fine-to-medium-grained quartz sand with varying percentages of shell and clay. Hardpan frequently occurs at the base of the quartz sands. The lower section consists of shell beds with interbedded limestones. Underlying the undifferentiated materials are the Pliocene Tamiami formations, the Miocene Hawthorn formation, Oligocene Suwanee Limestone, the Eocene Crystal River and Williston formations, the Avon Park Limestone, and the Lake City Limestone.

Several stratigraphic units can be differentiated based upon shallow borings drilled on the plant property. Sand with some heterogeneous fill material related to past site construction activity covers most of the surface. It is underlain by layers of clayey sand and clay to a depth of approximately 23 feet. These units mantle a thicker clay unit with numerous shell fragments that occurs from 15 feet to about 55 feet below the surface. A silty sand with a trace of clay was encountered at 55 feet near the termination depth of one deep boring on the site.

The water table at the site occurs at levels from just under the surface to about 5 feet below grade. Locally, the surficial aquifer and surface water will generally flow toward the Caloosahatchee River. However, at the site, the intake and discharge canal will affect groundwater near the power block area. A drainage canal that borders the plant property on the west will affect groundwater flow along the western portion of the waste treatment area.

k. Projected Water Quantities For Various Uses

It is estimated that 150 gallons per minute (gpm) will be needed for industrial processing water for uses such as boiler makeup and service water. For industrial cooling (once-through cooling water), no significant increase is projected in the current 451,000 gpm usage rate. Other facility water uses may include irrigation, potable use, etc. The total volume of these uses is estimated to be about 5 gpm.

l. Water Supply Sources By Type

For industrial processing, FPL anticipates that groundwater will be available. For cooling water, for the repowered unit, FPL plans to continue to use its existing allocation from the Caloosahatchee River in a once-through cooling mode. The new CT's will be air-cooled. After the conversion of these CT's into a CC unit, a cooling tower with blowdown (i.e., a closed system) is expected to be used.

m. Water Conservation Strategies Under Consideration

A plan to treat and recycle equipment wash water, boiler blowdown, and equipment area runoff for use as service water would reduce ground water consumption. FPL would anticipate this site being designed and classified as a wastewater zero-discharge site following the completion of the repowering work.

n. Water Discharges and Pollution Control

Heated water discharge will be dissipated using both the existing once-through cooling water system and a multi-cell cooling tower. Non-point source discharges are not anticipated to be an issue because surface water runoff will be collected and used to recharge the surficial aquifer. Treating and recycling equipment wash water, boiler blowdown, and equipment area runoff will minimize industrial discharges. Storm water runoff will be collected and used to recharge the surficial aquifer via a stormwater management system. Design elements will be included to capture suspended sediments. Various facility permits mandate various sampling and testing activities, which will provide indication of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

A combustion turbine-based repowering project, plus the addition of the new CT's/CC, at the Fort Myers site requires a natural gas pipeline to be installed. Florida Gas Transmission has initiated permitting to install and operate such a facility. Virtually no waste is associated with natural gas firing.

p. Air Emissions and Control Systems

A natural gas-fired facility would generally have air pollutant emissions, which are substantially lower than emissions from the current oil-fired boilers. While several technologies are available for nitrogen oxide (NOx) emissions control, FPL is using a dry-low-NOx combustion turbine design. In these devices, combustion is staged in order to reduce the formation of combustion-derived oxides of nitrogen. FPL has proposed NOx emission limits for this facility that will be among the lowest in the state once the facility is constructed. Sulfur dioxide and particulate emissions are intrinsically low due to the lack of sulfur and solids in natural gas fuel. Carbon monoxide and volatile organic compound emissions can each be controlled via the use of efficient combustion rather than through the use of add-on control devices. Carbon dioxide emission rates associated with burning natural gas are well below those of other liquid or solid fuels. While the Fort Myers plant site is located within 100 kilometers of a Class I area (Everglades National Park), the reduction in emissions associated with repowering is expected to improve the air quality in the area as compared to current levels. CC and CT facilities have been permitted at several locations throughout the state of Florida including near Class I areas. Dry-low-NOx combustor systems have been repeatedly demonstrated to be the Best Available Control Technology (BACT) for the control of NOx emissions for this technology pursuant to the requirements of the Clean Air Act.

q. Noise Emissions and Control systems

Lee County has a noise ordinance which limits noise at the receiving property line to 75 decibels. Noise emissions from the Fort Myers project s are not anticipated to approach this level based upon demonstrated noise control at similar natural gas-fired facilities (the Lauderdale plant in Broward County and the Martin plant in Martin County) and computer modeling of the anticipated noise emissions from the Fort Myers repowered plant. FPL will undertake studies to assure that noise level associated with the new CT's comply with Lee County noise standard.

r. Status of Applications

FPL has received all the permits necessary to construct and start up the repowered plant and the two new CT units. FPL will apply for permits for the CT's – to - CC conversion at the appropriate time.

Preferred Site #2: Sanford Plant, Volusia County

The site is located on the 1,718–acre FPL Sanford property just west of Lake Monroe on the north bank of St. Johns River in Volusia County. Current facilities on the site include three steam electric generating units (one with a nominal rating of 150 MW and two with nominal ratings of 400 MW). The site is within the city limits of Debary and the community of Debary is located approximately 2 miles to the northwest. The town of Deland is approximately 4 miles west of the site. The site has direct access to a four-lane highway, State Road (SR) 17-92, and barge access is available. The Sanford site has been listed as a potential or preferred site in previous FPL Site Plans.

FPL is currently in the process of adding new capacity at the Sanford site by replacing two existing oil-and gas-fired units (i.e., existing units #4 and #5) with advanced natural gas-fired combustion turbines (CT's) and heat recovery steam generators (HRSG's). This type of steam generation replacement is commonly called "repowering".

This repowering will enable FPL to produce significantly more electrical output with nearly the same environment impact. The repowering of units # 4 and # 5 will each produce approximately 570 additional MW during Summer conditions, and approximately 670 additional MW of generation during Winter conditions, beyond the current capabilities of these units. The two repowered units # 5 and # 4 are scheduled to be in-service by mid-2002 and late-2002, respectively. The existing 150 MW unit # 3 at Sanford will be unaffected by the repowering of units # 5 and # 4.

a. and b. U.S. Geological Survey (USGS) May and Proposed Facilities Layout Map

A USGS map of the Sanford plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A large part of the property is covered by the 1,100-acre closed-cycle-cooling pond which occupies almost all of the northern portion of the site. The remainder of the site is primarily rangeland and the power plant facilities.

The surrounding land use is largely crop land and pasture. To the east of the plant there is a small residential area and some commercial/industrial land use. There are some residential areas mixed in with the agricultural areas located between the site and the St. John's River to the west To the south is the St. Johns River and residential homes and commercial/industrial businesses are located along the south side of the river.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

   Small, scattered wooded areas can be found on the site. There are two small areas of wetland marsh on the site and a few acres of wetland forest along the riverbank. There are some wooded areas on the site, primarily upland coniferous forest. Forested and non-forested wetlands can be found to the west, adjacent to the river. Rover and wetland areas towards the northwest are designated as part of the Wekiwa River Aquatic Preserve and Wekiwa River State Preserve.

2. Listed Species

   One inactive bald eagle (Haliaeetus leucocephalus: Federal - and - State listed as Threatened) nest has been found on the site. Bald eagles have also nested in the Lake Monroe area. There are a number of other eagle nests in the vicinity of the site, primarily along the river. The Florida Natural Areas Inventory (FNAI) reports several Scrub Jay populations (Aphelocoma coerulescens: Federal – and - State listed as Threatened) located in scrub vegetation to the northwest of the site. West Indian Manatees (Trichechus manatus: Federal – and - State listed as Endangered) have also been found in this area.

3. Natural Resources of Regional Significance Status

The Wekiwa River Aquatic Preserve extends along the St. John's River in the vicinity of the plant.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option for the Sanford site is the repowering of two existing oil-and gas-fired boilers with natural gas-fired combustion turbines (CT's) and heat recovery steam generators (HRSG's) Advanced CT's can be installed on the existing facility property to make effective use of existing transmission facilities and infrastructure although some transmission line upgrades will be required. Steam produced in the new HRSG's will be directed to two of the existing steam turbines. Natural gas-fired facilities represent one of the cleanest, most efficient technologies currently available for capacity additions to FPL's system.

Mitigation options being considered in the repowering project at Sanford include the reduction in the use of ground water, the use of combustion technology that is inherently low in air pollutant emissions, reduction in the amount of solid waste generated, plumbing the sanitary waste system into the Volusia county system, and the significant reduction of oil barge traffic on the St. Johns River.

g. Local Governmental Future Land Use Designations

The site is designated as "Industrial Utilities" in the Local Government land use plan. The city is currently updating its Land Use Plan. It is expected that the name, but not the expected use designation, may change. Land use designation of the surrounding area is primarily Agricultural. There is an area of "Public Institution" around Lake Monroe to the southeast and a small area of "Mixed Use" to the west along Barwick Road.

h. Site Selection Criteria and Process

The Sanford plant has been selected as a preferred site due to a combination of system load and economic factors. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All are considered permittable.

i. Water Resources

For surface water supply, the available water resource is the St. John's River and / or the on-site cooling pond, which is periodically refilled from the St. John's River. For groundwater supply, the available resources are the shallow aquifer or the Floridan Aquifer.

j. Geological Features of Site and Adjacent Areas

The near-surface geology of Volusia County, like that of most of north central Florida, is represented by late Tertiary and Quaternary geologic units. Soils in the vicinity of the plant include unconsolidated Pleistocene to Recent sands, with intervening beds of shells and clay. These deposits form the reservoir for the surficial aquifer in the county. Deposits of Pliocene or Miocene clay with some sand underlie the aquifer. These low-permeability units serve to confine groundwater under pressure in the underlying porous limestone formations of Eocene age. These formations are part of the principal hydrologic unit referred to as the Floridian Aquifer. This aquifer, the top of which generally occurs through the region at or below 100 feet, is the major source of potable groundwater in Volusia County. Two faults, one trending north-to-south, the other trending east-to west, intersect a number of miles north of the site. Downward displacement of the fault is hypothesized as being approximately 60 to 100 feet.

k. Projected Water Quantities for Various Uses

FPL has estimated that 150 gallons per minute (gpm) would be required for industrial processing purposes (boiler makeup, service water, etc.). Note that Units # 5 and # 4 both currently take their cooling water directly from an on-site FPL cooling pond and are expected to continue to do so once the units are repowered. The cooling water needs for the repowered facilities are expected to increase over what is currently used, due primarily to the increased heat loading to the cooling pond that will result from operating the larger repowered units more than they have been operated in the past, and corresponding evaporative losses. Therefore, greater quantities of water may be used.

Existing Unit # 3 will use water from the St. John's River in a once-through cooling mode.

FPL also evaluated alternative sources of water to meet the expected needs of the site. It is anticipated that the existing off-site wells and the existing once-through cooling water system and cooling pond would continue to be used after the repowering project is completed, albeit the use of groundwater is expected to decrease significantly from past usage.

l. Water Supply Sources by Type

The available surface water supply source is the St. Johns River. The Floridan Aquifer is an available groundwater source for service water and boiler water.

m. Water Conservation Strategies Under Consideration

A plan to treat and recycle equipment wash water, boiler blowdown, and equipment area runoff for use as service water would reduce groundwater consumption.

n. Water Discharges and Pollution Control

Heated water discharge will be dissipated using the existing once-through cooling water system. Non-point source discharges are not anticipated to be an issue because surface water runoff is planned to be collected and reused. Treating and recycling equipment wash water, boiler blowdown, and equipment area runoff will minimize industrial discharges. Storm water runoff will be collected and used to recharge the surficial aquifer via a stormwater management system. Design elements will be included to capture suspended sediments. Various facility permits mandate various sampling and testing activities, which will provide indication of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The repowered facilities at the Sanford site would require a larger natural gas pipeline to be installed. FPL has contracted with Florida Gas Transmission Company (FGT) to permit, install, and operate such a facility. Virtually no waste is associated with natural gas firing.

p. Air Emissions and Control Systems

A natural gas-fired facility would generally have air pollutant emissions which are substantially lower than emissions from the current oil-fired boilers. While several technologies are available for nitrogen oxide (NOx) emissions control, the most appropriate candidate for the Sanford site is a dry-low-NOx combustion turbine design type. In these types of devices, combustion is staged in order to reduce the formation of combustion-derived oxides of nitrogen. Sulfur dioxide and particulate emissions are intrinsically low, due to the lack of sulfur and solids in natural gas fuel. Carbon monoxide and volatile organic compound emissions can each be controlled via the use of efficient combustion, rather than through the use of add-on control devices. CC and CT facilities have been permitted at several locations throughout the state of Florida. Dry-low-NOx combustor systems have been repeatedly demonstrated to be the Best Available Control Technology (BACT) for the control of NOx emissions for this technology pursuant to the requirements of the Clean Air Act.

q. Noise Emissions and Control Systems

Noise emissions from the project are not anticipated to be significantly different from current levels at the existing plant. FPL will install appropriate sound attenuation devices such as insulation on high-energy piping systems in order to ensure that sound levels do not exceed allowable levels. Similar natural gas-fired facilities (the Lauderdale plant in Broward County and the Martin plant in Martin County) have been constructed and operated without exceeding allowable noise levels.

r. Status of Applications

FPL has now acquired all permits needed to commence construction. Modifications to operating permits will continue to be pursued as necessary through 2001.

Preferred Site #3: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District (SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad.

The Martin site was identified in 1987 as a preferred location for development of coal gasification/combined cycle electric generation facilities and subsequent FPL Site Plans have continued to identify this site as a preferred site.

The existing 2,588 MW of Summer generating capacity at FPL's Martin plant occupies a portion of the approximately 11,300-acre Martin site which is wholly owned by FPL. The generating capacity is made up of two steam units (units # 1 and # 2), plus two combined cycle units (units # 3 and # 4). The site includes a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

Additional generating capacity will be added to the site in several stages. First, two combustion turbines (CT's) are being added to the site in 2001. These two CT's will then be converted into one combined cycle (CC) unit in 2005. An additional CC unit (Martin Unit # 5) will also be added in 2005. Finally, one more CC unit (Martin Unit # 6) will be added in 2006.[5]

The two new peaking CT's are currently under construction will add 298 MW (Summer) and 362 MW (Winter) of additional capacity to FPL's system. The later conversion of these two CT's to one CC unit will add approximately 249 MW (Summer) and 234 MW (Winter) of capacity. The addition of the Martin units # 5 and # 6 will each add approximately 547 MW (Summer) and 596 MW (Winter).

a) and b) U.S. Geological Survey (USGS) Map and Proposed Facilities Layout Map

A USGS map of the Martin plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c) Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d) Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres. To the east of the power plant

[5] Ultimately, coal gasification facilities may be constructed and operated to supply coal-derived gas to existing Units #3 and #4 and/or these new CC units, if economically justified. FPL currently has no plans to introduce coal gasification at the site Coal gasification would not produce additional megawatts, so it is not discussed further in this document. Approx. 1,300 acres could potentially be used to accommodate the associated coal handling, coal storage, by-product handling, and storage facilities which would be constructed if coal gasification is implemented In such a case, natural gas and/or distillate fuel coil could serve as backup fuels.

there is an area of mixed pine flatwood with a scattering of small wetlands. To the north of the reservoir there is a 1,200-acre area which has been set aside as a mitigation area. There is peninsula of wetland forest on the west side of the reservoir which is named the Barley Barber Swamp. The Barley Barber Swamp encompasses 400 acres and is preserved as a natural area. There us also a 10 kilowatt (KW) photovoltaic energy facility at the south end of this site.

e) General Environment Features On and In The Site Vicinity

1) Natural Environment

As noted above, the Barley Barber Swamp is located on the site. There is also a 1,200-acre mitigation area in the northern area of the site where wetlands and uplands have been restored. Along the south and west sides of the cooling pond is an area where the vegetation has been allowed to return to its natural state in order to serve as a wildlife corridor. FPL has preserved a Florida Panther corridor along the west side of the cooling pond. There are pine flatwoods and small scattered wetlands to the east of the plant.

2) Listed Species

Construction and operation of new units at the site are not expected to affect any rare, endangered, or threatened species. There are two active Bald Eagle (Haliaeetus leucocephalus: Federal - and - State listed as Threatened) nests that have been on the site for many years. The Florida Natural Areas Inventory (FNAI) database notes a record of Eastern Indigo Snakes (Drymachon coralis coupert which are Federal - and - State listed as Threatened) in the Barley Barber Swamp. A number of other Bald Eagle nests and sightings of Eastern Indigo Snakes are reported by the FNAI database within a two-mile radius of the site. Infrequent sightings of Florida Panther have been made in the site area.

3) Natural Resources of Regional Significance Status

The Treasure Coast Regional Planning Council lists the "FPL Preserve", including the Barley Barber Swamp, as a Significant Regional Facility. Natural communities such as uplands and wetlands are also generically listed as Resources of Regional Significance.

4) Other significant features

FPL is not aware of any other significant features of the site.

f) Design Features and Mitigation Options

The design options are to add four additional CT's and two HRSG's which will comprise the Martin # 5 and #6 units, in 2005 and 2006, respectively. In addition, two new CT's will begin operation in mid – 2001. In 2005 they will be converted into one CC unit. Natural gas delivered via pipeline is envisioned as the fuel type for these units (with distillate serving as a backup fuel for the stand-alone CT's.). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation options being considered in the addition of this capacity at the existing Martin site include the capture and reuse of plant process water and rainwater. The facility already encompasses several preserved areas where wildlife is abundant.

g) Local Government Future Land Use Designations

Local government future land use designation for the site is "Public Utilities". Designations for the surrounding area are primarily "Agricultural". There are also limited areas of "Agricultural Ranchette", "Industrial", and a small "Commercial" area designation. To the southeast of the property, fronting on the St. Lucie Canal, there is an area designated for "Public Conservation".

h) Site Selection Criteria and Process

For the past several years, a number of FPL's existing power plant sites have been considered as potentially suitable sites for new or repowered generation. The Martin plant has been selected as a preferred site due to a combination of site, location, and economic factors. The Martin site has been selected as a preferred site due to a combination of electrical transmission and system load factors, plus economic considerations. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential site exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered permittable.

i) Water Resources

Surface water resources currently used at the Martin facility include the cooling pond, which takes its water from the St. Lucie canal. The available groundwater resource is the shallow aquifer which is used as a source of potable water and for service water for Units # 1 and # 2. Both of these sources are available for use with the site expansion.

j) Geological Features of Site and Adjacent Areas

FPL's Martin site is underlain by approximately 13,000 feet of sedimentary rock strata The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The deepest formation in Martin County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Lake City formation. The published information on the sediments comprising the formations below the Avon Park Limestone in western Martin County is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach counties.

k) Projected Water Quantities for Various Uses

The estimated additional quantity of water required for industrial processing is 130 gallons per minute (gpm) for uses such as boiler water and service water. FPL operates on-site water treatment systems for each of these uses. Cooling water for new Units # 5 and # 6, as well as for the other new CC unit which will result from the conversion of the 2 new CT's into a CC unit, will be supplied from the on-site 6,800-acre cooling pond. The CT's will be air-cooled until they are converted into a CC unit. Makeup water for the pond is taken from the St. Lucie canal. The current makeup water quantity to the cooling pond (approximately 4,800 gpm) is expected to be adequate for the proposed expansion. Water quantities needed for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l) Water Supply Sources by Type

All additional capacity at the site will utilize the existing on-site cooling pond as the source of cooling water and as a heat sink for the dissipation of cooling water heat. The cooling pond operates as a "closed cycle" system in which heated water from the generating units loses its heat as it is circulated within the pond and back around to the plant intake. Makeup water to the pond is withdrawn from the St. Lucie Canal as needed to replace net evaporation and seepage losses from the pond. Such needs will comply with the existing agreement between FPL and the South Florida Water Management District (SFWMD) regarding allocation of cooling water to the pond and with SFWMD's regulations for consumptive water use.

The existing water treatment system at the plant, which provides treated water for use in the Unit 1 and 2 boilers, as well as the HRSG's associated with Units 3 and 4, will be used to provide treated water for the two new, and expanded to provide treated water for New Unit # 5. To avoid impacts to the surficial aquifer, FPL and SFWMD have agreed that the process water for Units # 3 and # 4 can be obtained initially from the cooling pond, but upon completion of Units # 5 and # 6, process water for all four CC units will be obtained solely from the Floridan Aquifer via approximately 1,500-foot deep wells.

m) Water Conservation Strategies Under Consideration

Impacts on the surficial aquifer will be reduced by changing the source of plant process water to the Floridan aquifer, upon completion of Units #5 and #6. In addition, the facility captures and reuses process water whenever feasible, and manages stormwater in such a manner so as to recharge the surficial aquifer.

n) Water Discharges and Pollution Control

Heated water discharges will be dissipated in the cooling pond. Non-point source discharges are not an issue since there are none at this facility. Industrial discharges will be minimized by treating and recycling equipment wash water, boiler blowdown water, and equipment area runoff. Storm water runoff is collected and used to recharge the surficial aquifer via a stormwater management system. Design elements have been included to capture suspended sediments. Facility permits mandate various sampling and testing activities, which provide indication of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o) Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by multiple fuel delivery facilities. However, the addition of future natural gas-fired CC units would require an enlargement of the existing pipeline(s), the installation of a new pipeline, or the addition of another natural gas pipeline compressor station. There are currently two natural gas supply lines into the facility, as well as an oil pipeline, which serve the existing steam boilers and combined cycle generating units. The existing natural gas line will also serve the new CT's.

p) Air Emissions and Control Systems

FPL's plan for the two new CT's/CC and for new Units # 5 and # 6 are subject to "New Source Review" under Federal and State Prevention of Significant Deterioration (PSD) regulations. This review required these units to meet New Source Performance Standards (NSPS) and that Best Available Control Technology (BACT) be selected to control emissions of those pollutants emitted in excess of applicable PSD significant emission rates. The primary purpose of BACT analysis is to minimize the allowable increases in air pollutants and thereby increase the potential for future economic growth without significantly degrading air quality.

Air emission rates will be limited to levels far below NSPS requirements. In addition, BACT determination was established for the following pollutants: sulfur dioxide (SO_2) , sulfuric acid mist (H_2SO_4), nitrogen oxides (NO_x), particulates (PM_{10} and TSP), carbon monoxide (CO), volatile organic compounds (VOC), lead, beryllium, mercury, and inorganic arsenic. By stipulation, the Department of Environmental Protection (DEP) has determined final BACT for Units # 3 and # 4 firing natural gas and distillate oil. Emission limitations and conditions concerning development of subsequent units at the site (e.g. the two CT's/CC and Units # 5 and # 6) reflect a preliminary BACT determination for those phases to support certification of ultimate site capacity and shall be determined finally upon review of supplemental applications.

Emission limits for the new CT's currently under construction reflect BACT limits of 10 ppm for natural gas firing and 42 ppm for distillate oil firing. Different limits were also established for operation of the peaking units in power augmentation and peaking modes. FPL projects that lower emission levels to those listed above will be required for the conversion of the CT's to CC operation and for the operation of new Units # 5 and # 6.

q) Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise will be below current noise levels at the residents nearest the site. Noise from the operation of the new units will also be within allowable levels.

r) Status of Applications

A Site Certification application was filed in December, 1989, for the construction and operation of the Martin Coal Gasification/Combined Cycle project under the Florida Electrical Power Plant Siting Act.

On June 15, 1990, the Public Service Commission issued a Determination of Need Order for proposed Martin Units # 3 and # 4. This determination of need applies only to the first phase of the Project, or 832 MW of combined cycle generation. The Siting Board issued a Land Use Order on June 27, 1990. The Certification Hearing was held on November 5-7, 1990. As mentioned earlier, on February 12, 1991, the Governor and Cabinet, serving as the Siting Board, approved the construction and operation of natural gas-fired combined cycle Units # 3 and # 4 and determined that the Martin Site has capacity to accommodate additional combined cycle units fueled by natural gas, fuel oil, or coal-derived gas produced at the site which will encompass new Units # 5 and # 6.

Since the initial certification in 1991, the certification has been modified five times to provide authorization for items such as CT testing, increasing the cooling pond elevation, incorporating changes from other permits, and incorporating a custom fuel monitoring program. For the addition of the two CT's mentioned above, FPL obtained a sixth modification to the existing site certification in August 2000.

In order to convert these two CT's from simple cycle to CC configuration, a seventh modification to the Site Certification will be required. FPL will file an application for this modification at the appropriate time.

Preferred Site #4: Midway Substation Property, St. Lucie County

The site is located on the 122-acre Midway Substation property. Current facilities on the site include an electric substation. The site has direct access to a two-lane highway, State

Road (SR) 712. The nearest town is White City, which is approximately 5 miles east of the site. The City of Fort Pierce is approximately 9 miles northeast of the site. The Midway site has not previously been listed as a potential or preferred site in previous FPL Ten Year Power Plant Site Plans.

FPL is planning to add new capacity by constructing a combined cycle (CC) gas-fired facility on the property. The new plant would consist of two combustion turbines (CT's), two heat recovery steam generators (HRSG's) and one steam turbine-generator. This addition will add approximately 547 MW (Summer) and 596 MW (Winter) to FPL's system. The construction of the CC unit is planned to be completed and the plant in service by mid-2005.

a. and b. U.S. Geological Survey (USGS) May and Proposed Facilities Layout Map

A USGS map of the Midway Substation site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

The land on the site is currently dedicated to industrial and agricultural use. Much of the site is currently not being used.

Developed portions of the adjacent properties are primarily agricultural (orange groves and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and wetlands.

e. General Environmental Features On and In the Site Vicinity

1) Natural Environment

The majority of the sixty-acre site is improved pasture, with active grazing by cattle occurring over the entire site. There is a strip of upland pine/palmetto community and small, isolated wetlands between the transmission corridor to the east and the improved pasture to the west. The isolated wetlands are of moderate ecological value and could be avoided by using the improved pasture to the west. There is an area of historic wetlands in the western improved pasture area of very low functional value over which the Florida Department of Environmental Protection will claim jurisdiction. Minimal mitigation ratios would be expected based on the condition of the historic wetlands.

2) Listed Species

One active gopher tortoise (*Gopherus polyphemus:* State species of special concern) nest was observed in the pine/palmetto upland area. No indication of any other listed species was observed.

3) Natural Resources of Regional Significance Status

The Savannas State Preserve lies approximately 7 miles to the east of the proposed site.

4) Other Significant Features

FPL is not aware of any other significant features of this site.

5) Natural Resources of Regional Significance Status

No Natural Resource of Regional Significance is identified on the plant site in the Southwest Florida Regional Strategic Policy Plan.

6) Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option currently being pursued for the Midway site is the construction of a 500 MW (nominal) CC unit, using natural gas-fired CT's and HRSG's. All of this new generation equipment will be installed on the existing facility property and make effective use of existing transmission facilities and infrastructure although some transmission line upgrades will be required. Steam developed in the new HRSG's will be directed to a new steam turbine.

Operation of the Midway unit is dependent upon securing a firm natural gas supply to the site which is both sufficient for fueling the electrical capacity involved and economically attractive. FPL is exploring a contract with Florida Gas Transmission (FGT) for this fuel supply.

Mitigation options being planned for the capacity additions at Midway include: the capture and reuse of plant process water, the use of combustion technology that is inherently low in air pollutant emissions, and the use of gray water if available,

g. Local Government Future Land Use Designations

A Comprehensive Plan Amendment, a rezoning and a Conditional Use permit will be required from St. Lucie County; followed by a Site Plan review & approval. The current zoning for the substation is "Utility", but is "MXD" (mixed use development) on the rest of the property. FPL will need to change that to "Utility" in order to develop the site.

Two public hearings would be required; one for the Comprehensive Plan, Rezoning and Conditional Use permit (if FPL is able to file all simultaneously), and a second for the Site Plan approval.

h. Site Selection Criteria and Process

For the past several years, many of FPL's existing facility sites have been considered potentially suitable sites for new, expanded, or repowered generation. The Midway facility has been selected as a preferred site due to a combination of electrical transmission and system load factors, plus economic considerations. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered permittable.

i. Water Resources

No surface water source is available at the site. The groundwater source would either be the shallow aquifer or a local source of gray water.

j. Geological Features of Site and Adjacent Areas

The site lies in the Atlantic Coastal Lowlands physiographic province. The Lowlands are characterized by monotonously flat, low elevations (less than 25 feet above mean sea level) that are swampy and poorly drained. These lowlands (or flatlands as they are also called) represent the shallow, flat bottoms of ancient seas.

Thick sequences of sedimentary rocks overlie the crystalline basement rocks. These sediments are over 12,000 feet thick in eastern St. Lucie county. Sediments within a few hundred feet of the surface generally consist of clastics, such as sands, silts and clays; and carbonates, such as limestones, dolomites or shell beds. Many of these lithologic units are interbedded or interfingered and are gradational from one to another. Sediments exposed at the surface range from Miocene age (26 to 12 million years ago) through Pleistocene age (3 to 2 million years ago) to Recent age. A veneer of Pleistocene sand covers almost all of St. Lucie county. Marine processes laid down the shell beds, clays, sands and limestone. During the last two million years of Pleistocene time, the sea level rose more than 100 feet and fell more than 200 feet below present sea levels. These sea level fluctuations occurred several times, alternately covering and exposing parts of the Floridan Plateau. Each significant change in sea level created a different environment of deposition for any given location across the relatively flat Plateau. The result of these sea level changes is a very complex interbedding and interfingering of heterogeneous lithologies in the subsurface stratigraphy.

k. Projected Water Quantities For Various Uses

It is estimated that 150 gallons per minute (gpm) will be needed for industrial processing water for uses such as inlet air-cooling, NOx control during distillate oil firing, and service water. Other facility water uses may include irrigation, potable use, etc. The total volume of these uses is estimated to be about 5 gpm.

l. Water Supply Sources By Type

For industrial processing and cooling water, FPL plans to use either gray water or groundwater.

m. Water Conservation Strategies Under Consideration

FPL plans to utilize an auxiliary equipment cooling system that will recirculate cooling water through the plant equipment, thus minimizing water losses.

n. Water Discharges and Pollution Control

Water discharges will be minimal. Storm water runoff will be collected and used to recharge the surficial aquifer via a stormwater management system. Design elements will be included to capture suspended sediments. It is anticipated that various facility permits will mandate various sampling and testing activities, which will provide indication of any pollutant discharges. The facility will employ a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

A CC project at the Midway site requires a natural gas pipeline to be installed. FPL anticipates working with a local natural gas utility to permit, install, and operate such a facility. Virtually no waste is associated with natural gas firing.

p. Air Emissions and Control Systems

A natural gas-fired CC facility would generally have air pollutant emissions that are among the lowest currently available for electric power production. While several technologies are available for nitrogen oxide (NOx) emissions control, FPL plans to use a dry-low-NOx combustion turbine design. In these devices, combustion is staged in order to reduce the formation of combustion-derived oxides of nitrogen. FPL anticipates NOx emission limits for this facility that will be among the lowest in the State once the facility is constructed. Sulfur dioxide and particulate emissions would be intrinsically low due to the lack of sulfur and solids in natural gas fuel. Carbon monoxide and volatile organic compound emissions can each be controlled via the use of efficient combustion rather than through the use of add-on control devices. Carbon dioxide emission rates associated with burning natural gas are well below those of other liquid or solid fuels. CC and CT facilities have been permitted at several locations throughout the State of Florida. Dry-low-NOx combustor systems have been repeatedly demonstrated to be the Best Available Control Technology (BACT) for the control of NOx emissions for this technology pursuant to the requirements of the Clean Air Act.

q. Noise Emissions and Control systems

St. Lucie County has a noise ordinance which limits noise at the receiving property line to 55-75 decibels, depending upon the adjacent land use classification. Noise emissions from the Midway project are not anticipated to approach these levels based upon demonstrated noise control at similar natural gas-fired facilities (the Lauderdale plant in Broward County and the Martin plant in Martin County) and computer modeling of the anticipated noise emissions from the Midway facility. FPL will undertake studies to assure that noise level associated with the new CT's comply with St. Lucie County noise standard.

r. Status of Applications

FPL will apply for all the permits necessary to construct and start up the new CC unit at the appropriate time.

IV.F.2. Potential Sites

Three FPL-owned sites are identified as the next most likely potential sites for future generation after the four preferred sites just discussed. These three sites are considered the next most likely potential sites due to considerations of space, infrastructure, and accessibility to fuel and transmission facilities. These sites are located in Brevard, Palm Beach, and Broward Counties. These sites are suitable for different capacity levels and technologies, and they will remain as potential sites pending future decisions on how best to meet the timing and magnitude of FPL's future capacity needs.[6]

Each of these potential sites offers advantages and disadvatanges relative to engineering considerations and/or costs associated with the construction and operation of feasible technologies. In addition, each potential site has different characteristics, which could require further definition and attention. For purposes of estimating water usage amounts, it is assumed that a natural gas-fired CC unit would be the technology of choice for any capacity additions at the sites.

Permits are presently considered to be obtainable for all three sites, assuming measures can be taken to mitigate any particular site-specific environmental concerns. None of the sites exhibit any significant environmental constraints. The potential sites are briefly discussed below. (Note: The order in which the sites are discussed below does not reflect a relative ranking of these sites in regard to how likely it is for FPL to add capacity at the site.)

Potential Site #1: Cape Canaveral Plant, Brevard County

The site is located on the FPL Cape Canaveral property in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The existing facility consists of two 400 MW (nominal) steam boiler type generating units.

a) U.S. Geological Survey (USGS) Map

A USGS map of the Cape Canaveral plant site is found at the end of this chapter.

b) and c) Land Uses and Environmental Features

[6] As has been described in previous FPL Plant Site Plans, FPL also considers a number of other sites as possible sites for future generation additions These include the remainder of FPL's existing generation sites as well as non-FPL-owned sites located in Hardee, Highlands, Glades, and Hendry Counties.

This site is located on the Indian River. The land is primarily dedicated to industrial use with surrounding grassy areas and a few acres of remnant pine forest. The land adjacent to the site is dedicated to light commercial and residential use. There are no significant environmental features on the site.

d) and e) Water Quantities and Supply Sources

FPL projects that an increase of up to 260 gallons per minute (gpm) would be required for industrial processing use (boiler makeup, service water, etc.) It is expected that industrial cooling water needs could be met using the current 550,000 gpm once-through cooling water quantity. For industrial processing, FPL would use existing on-site wells. For industrial cooling, the Indian River would continue to be utilized.

Potential Site #2: Riviera Plant, Palm Beach County

This site is located on the FPL Riviera Plant property in Riviera Beach, Palm Beach County. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (nominal) steam boiler generating units and one retired 50 MW generating unit.

a) U.S. Geological Survey (USGS) Map

A USGS map of the Riviera plant site is found at the end of this chapter.

b) and c) Land Uses and Environmental Features

The land on the site is primarily covered by the existing generation facilities with some open maintained grass areas. There is a small manatee viewing area on the site which is operated seasonally by FPL. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development. The site is located on the Intracoastal Waterway near the Lake Worth Inlet.

d) and e) Water Quantities and Supply Sources

Additional industrial processing water needs are estimated to be up to 40 gallons per minute (gpm). Industrial cooling water needs are estimated to be up to 54,000 gpm using the existing once-through cooling water system. The existing municipal water supply would be used for industrial processing water if additional generating capacity is placed at Riviera. For once-through cooling water, FPL would continue to use Lake Worth as a source of water.

Potential Site #3: Port Everglades Plant, Broward County

This site is located on the 94-acre FPL Port Everglades plant site in Port Everglades, Broward County. The site has convenient access to State Road (SR) 84 and Interstate 595. Currently, direct barge access is not available. A rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (nominal) and two 400 MW (nominal) sized units.

a) U.S. Geological Survey (USGS) Map

A USGS map of the Port Everglades plant site is found at the end of this chapter.

b) and c) Land Uses and Environmental Features

The land on the site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

d) and e) Water Quantities and Supply Sources

FPL estimates that up to 130 gallons per minute (gpm) of industrial processing water would be required for uses such as boiler makeup, fogger usage, and service water. FPL would expect to use the existing municipal water supply for industrial process water. For cooling water, FPL would anticipate that the existing 320,000 gpm once-through cooling seawater source would continue to be used.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning considers two type of transmission constraints. External constraints deal with FPL's ties to its neighboring systems. Internal constraints deal with the flow of electricity within the FPL system.

The external constraints are important since they affect the development of assumptions for the amount of external assistance which is available and the amount and price of economy energy purchases. Therefore, these external constraints are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the transfer capability as well as historical levels of available assistance. FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission constraints or limitations are addressed in developing the costs for siting new units at different locations. Site-specific transmission costs are developed for each different unit/unit location option.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. *Discuss any changes in the generation expansion plan as a result of sensitivity tests* to the base case load forecast.

As discussed in Chapter III of this document, FPL performs economic analyses of competing resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI) and Stone and Webster Management Consultants, Inc. The resource plan reflected in this document emerged as the resource plan with the least impact on FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach) and on the present value of revenue requirements for the FPL system.[7]

FPL performed three sensitivity analyses as part of its 2000 resource planning work or in preparation for this site plan filing. One of these analyses used a load forecast which differed from FPL's base case or "Most Likely" load forecast. (The other two sensitivity analyses are discussed in Discussion Items # 4 and # 6.)

The first sensitivity analysis examined a case in which a "High Load" forecast was combined with a "Low Price" fuel forecast In this case, FPL's need for incremental resources moved forward in time to the year **2001**. This accelerated need, if assumed to be met solely through the construction of new units (as is the primary focus of the Site Plan filing), could only be addressed by combustion turbines or new purchases in the early years. Subsequent years would likely be addressed by new combined cycle units.

In its 2000 resource planning work, FPL did not conduct a sensitivity case involving a "Low Load" forecast. Since the system reliability analysis which utilized the "Most Likely" load forecast showed that new units were not needed until 2005, it was clear that a "Low Load" case would not have shown a power plant decision needed prior to 2005. Therefore, FPL saw no value in analyzing such a "Low Load" case in its 2000 planning work.

The construction - only options selected in the resource plans (purchase options are not shown) for FPL's "Most Likely" case, and for the first sensitivity case discussed above, are presented on the following page in Table V.1.

[7] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical In such cases (as in FPL's 2000 resource planning work), FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Table V.1

Selected Power Plant Construction Options For Base and Sensitivity Cases

Year	"Most Likely" Load and "Most Likely" Fuel Price Base Case	"High" Load and "Low" Fuel Price Scenario Case
2000	----	----
2001	2 CT's at Martin Ft. Myers Repowering: Initial Phase	2 CT's at Martin Ft. Myers Repowering: Initial Phase 3 Unsited CT's

2008	----	Unsited CC Unit # 3
2009	Unsited CC Unit # 2	Unsited CC Unit # 4
2010	Unsited CC Unit # 3 Unsited CC Unit # 4 Unsited CC Unit # 5	Unsited CC Unit # 5 Unsited CC Unit # 6

Key: CT = Combustion Turbine
CC = Combined Cycle Unit

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its base case or "Most Likely" fuel price forecast are discussed in Chapter III of this document.

The "High Price" and "Low Price" fuel forecasts are developed based on a review of major supply and demand assumptions for oil and natural gas The "High Price" forecast assumes that the worldwide demand for petroleum products will grow somewhat rapidly throughout the planning horizon. Non-OPEC crude oil supply will remain unchanged as improved drilling technology permits only the replacement of depleting fields. As a result, OPEC's market share will grow more rapidly than in the base case which would result in higher oil prices. In addition, this forecast assumes that domestic natural gas demand will grow somewhat rapidly, primarily due to significant increases in the construction of combined cycle generation. Domestic natural gas production will increase slowly as improved drilling technology permits only the replacement of depleting fields. This will result in higher natural gas imports, including Liquified Natural Gas (LNG), than in the base case which, in turn, results in higher natural gas prices.

The "Low Price" fuel forecast assumes that worldwide demand for petroleum products will grow slowly over the forecast horizon. It also assumes that non-OPEC crude oil supply will grow rapidly due to significant improvement in drilling technology and that OPEC's market share will only make small gains relative to the base case. In regard to natural gas, the "Low Price" forecast assumes that domestic demand for natural gas will grow slowly over the forecast horizon and that domestic production will increase faster than in the base case. These assumptions result in lower oil and gas price forecasts.

FPL did test the sensitivity of its resource plan to a "Low Price" fuel forecasts in conjunction with a "High Load" forecast. The results of these analyses are presented above in FPL's response to Discussion Item # 2. FPL did not test the sensitivity of its resource plan to a "High Price" fuel forecast in its 2000 IRP work. Although FPL typically performs a sensitivity analysis on a combined "Low Load"/ "High Price" fuel forecast, such an analysis would not have shown a need for new power plants before 2005 (as discussed in Discussion Item #2.) Consequently, this analysis was not performed in FPL's 2000 planning work.

Discussion Item # 4: **Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.**

In addition to the sensitivity analyses discussed above which examined the impact of "High Load" and "Low Price" fuel forecasts, FPL also performed a sensitivity analysis in which the differentials between oil prices, gas prices, and coal prices were kept constant over the planning horizon. FPL performed this analysis solely due to the fact that it was included in the FPSC's list of specified information for the Site Plan filing. FPL believes that the likelihood of a constant differential between fuel prices occurring over the planning horizon is very small. In order to perform this "acid test" analysis, FPL used the initial year price forecast for each fuel and kept those prices constant throughout the planning horizon

The results of this scenario analysis were identical to that of the Base Case.

Discussion Item # 5: **Describe how generating unit performance was modeled in the planning process.**

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, and capacity output ratings and heat rate information. Schedules 1 and 8 present the capacity output ratings of FPL's existing units. The values used for outages and heat rates are consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add over the planing horizon is presented on Schedule 9. Please refer to that schedule.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

The key financial assumptions used in FPL's 2000 resource planning work were 45% debt and 55% equity FPL capital structure; projected debt cost of 7.6%; and an equity return of 11.8%. These assumptions resulted in a weighted average cost of capital of 9.9% and an after-tax discount rate of 8.6%. These assumptions were used in FPL's base case or "Most Likely" forecast case analysis, and in its sensitivity analyses of alternate load and/or fuel price forecasts.

In order to test the sensitivity of the resource plan to a different set of financial assumptions, FPL performed an analysis in which the capital financing structure was changed to one which might be more typical of a case involving third-party financing of a new power plant. This alternate financing structure was assumed to be one made of 80% debt and 20% equity. The returns on debt and equity were assumed to be the same as for FPL's "Most Likely" case 7.6% and 11.8% respectively. These assumptions result in a weighted average cost of capital of 8.4% and an after-tax discount rate of 6.1%.

The results of this "alternate financial case" sensitivity analysis were the same as for FPL's "Most Likely" or Base Case analysis.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). However, in its 2000 planning work FPL utilized a net present value of system revenue requirements as the basis for comparing options and plans. (As discussed in response to Discussion Item # 2, both the electricity rate basis and the system revenue requirement basis are identical when DSM levels are unchanged between competing plans. Such was the case in FPL's 2000 planning work.)

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL traditionally uses two generation reliability criteria in its resource planning work. These are a minimum 15% Summer and Winter reserve margin and a maximum of 0.1 days per year loss-of-load-probability (LOLP). However, in its 2000 planning work, FPL also used a third criterion: a minimum 20% Summer and Winter reserve margin which applies starting with the Summer of 2004. This new criterion was the result of an agreement reached between FPL, FPC, TECO, and FPSC in Docket No. 981890-EU. These reliability criteria are discussed in Chapter III of this document. Please refer to that chapter.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the planning criteria established by the North American Electric Reliability Council (NERC) in its *Planning Standards*. FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Planning Standards* are available on the internet (http://www.nerc.com/~filez/pss-psg.html).

In addition, FPL has developed a Facility Connection Requirements (FCR) document as well as a Facility Rating Methodology document that are also available on the internet (http://www.enx.com/FPL/fpl_home.html).

Thermal ratings for specific transmission lines or transformers are found in the load flow cases that are available on the internet (http://www.enx.com/FPL/fpl_home.html). The normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138, 500	0.95	1.05
230	0.95	1.06

There may have been isolated cases for which FPL may have determined it prudent to deviate from the general criteria stated above. The overall potential impact on customers, the probability of an outage actually occurring, as well as other factors may have influenced the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption is evaluated over time. Data is collected from non-participants in order to establish a non-DSM technology baseline. Participants' data is compared against non-participants' data to establish usage patterns, demand impacts and to validate engineering assumptions.

FPL utilizes any or all of three major impact evaluation analysis methods in a manner that most cost-effectively meets the overall impact evaluation objectives. These three major impact evaluation analysis methods are: engineering analysis, statistical billing analysis, and on-site metering research. As DSM evaluations proceed over time, the components to be analyzed and the periods for which data is available will increase, resulting in continual enhancements in the scope and accuracy of reported evaluation results.

Finally, for those DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

FPL's resource planning process is designed to address various "strategic concerns" or areas of uncertainty. There are 6 areas of uncertainty that FPL seeks to address in its resource planning work: load growth, fuel price, transmission system constraints, environmental regulations, evolving technology, and competitive risk.

In regard to uncertainty about both load growth and fuel price, FPL addressed this by developing a resource plan which used a combination of a "High Load" forecast and a "Low Price" fuel forecast, as is discussed in Discussion Item # 3.(In response to the list of information specified by the FPSC for inclusion in the Site Plan filing, FPL also developed a resource plan which used an "acid test" fuel price forecast. This is discussed in regard to Discussion Item # 4.) In addition, uncertainty about fuel prices is addressed in fuel conversion efforts such as repowering projects now planned at FPL's Fort Myers and

Sanford sites and in retaining the capability to burn more than one fuel in a number of FPL generating units.

Uncertainty regarding transmission system constraints is addressed by annually updating assumptions about how much assistance may be available to FPL from outside FPL's service territory as well as assumptions relating to transmission constraints within FPL's system. In regard to uncertainty about environmental regulations, FPL's policy has always been that it will comply with all existing environmental laws and regulations. In that regard, FPL's resource planning analyses include all reasonably known costs of complying with these laws and regulations. Furthermore, in regard to potential new environmental regulations, FPL believes that its efforts to maintain the ability to burn varying grades of oil or burning either oil or natural gas at numerous plants, and to expand the use of natural gas (through the planned repowering projects at Fort Myers and Sanford, and the planned addition of new natural gas-fired combined cycle units), should allow FPL to reasonably respond to a variety of potential environmental regulations.

Uncertainty about evolving technology's potential impact on resource plans is best addressed by not committing to resource additions before it is necessary to do so. (In most cases, this approach also benefits the economics of the resource plan.) This minimizes the chance that a newly emerged technology will turn out to be a more economical choice than what the utility has already committed to. Uncertainty about evolving technology is also reduced by maintaining close contact with equipment vendors in order to better understand what the developmental status is of various generating technologies.

Finally, an increasingly important consideration in FPL's planning process is that of competitive risk. FPL's resource planning process is designed to identify the resource plan which best minimizes system average electric rates in order to keep FPL's service competitive in the evolving utility industry. Also, because of the inherent uncertainty associated with an evolving industry, long-term purchase commitments are undesirable. FPL seeks to avoid/minimize such commitments in its planning.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been discussed, the near - term elements of FPL's capacity additions are the repowering of its Fort Myers and Sanford plants, the addition of new combustion turbines (CT's) at Martin and Fort Myers (which will later be converted into CC units), and a number of firm capacity, short-term purchases. The incremental capacity from the two repowering projects comes from the addition of new CT's and heat recovery steam generators (HRSG's). FPL is acquiring the repowering-related CT's, plus the other CT's for Martin and Fort Myers, and the HRSG's through a bid process which will combine cost and performance considerations. The firm capacity short-term purchases are being acquired through negotiations.

The later capacity additions projected in FPL's Site Plan document will likely be carried out following the issuance of a capacity solicitation to potential suppliers at an appropriate time, if that approach represents the best vehicle to offer the lowest cost new generating capacity. FPL notes that its experience in 2000 in obtaining transmission cost estimates (after the FERC – required separation of its transmission planning group) leads FPL to question whether a solicitation process can still provide total cost estimates to a meaningful number of parties in the relatively short time a solicitation decision will be needed.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

FPL's plans do not include any new or upgraded transmission lines during the 2001 – 2010 time period which would need to be certified under the Transmission Line Siting Act (403.52 – 403.536, F.S.)

1/ These ratings are peak capability.
2/ The net capability ratings represent Florida Power & Light Company's share of St. Johns River Park Unit No 1 and No 2, excluding Jacksonville Electric Authority (JEA) share of 80%.; SJRPP receives coal by water (WA) in addition to rail
3/ These ratings represent Florida Power & Light Company's share of Scherer Unit No 4, adjusted for transmission losses

Historical Values (1991 - 2000):

Cols. (2) - (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Cols (7&9)), and MAY incorporate the effects of load control IF load control was operated on these peak days Therefore, Col. (2) represents the actual Net Firm Demand
Cols (5) - (9) represent actual DSM capabilities starting from January 1988
Note that the values for FPL's former Interruptible Rate are incorporated into Col (8), which also includes CILC and GS-LC
Col (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak Col (10) is derived by the formula Col. (10) =Col (2) - Col.(6) - Col (8)

Projected Values (2001 - 2010):

Cols. (2) - (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control The effects of conservation implemented prior to 2000 are incorporated into the forecast.
Cols. (5) - (9) represent all incremental conservation and cumulative load control. These values are projected August values and are based on projections with a 1/2000 starting point.
Col (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak Col (10) is derived by using the formula Col (10) =Col (2) - Col (5) - Col (6) - Col (7) - Col (8) - Col (9)

2008/09	22,586	135	22,451	0	1,473	251	497	86	20,279
2009/10	22,978	135	22,843	0	1,480	272	500	93	20,633

Historical Values (1991/92 - 2000/01):

Cols (2) - (4) are actual values for historical winter peaks As such, they incorporate the effects of conservation (Cols. (7&9)), and MAY incorporate the effects of load control IF load control was operated on these peak days. Therefore, Col (2) represents the actual Net Firm Demand
Cols (5) - (9) represent actual DSM capabilities starting from January 1988
Note that the values for FPL's former Interruptible Rate are incorporated into Col (8), which also includes CILC and GS - LC
Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak Col. (10) is derived by the formula: Col.(10) = Col (2) - Col (6) - Col (8)

Projected Values (2001/02-2009/10):

Cols. (2) - (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 1997 are incorporated into the forecast
Cols. (5) - (9) represent all incremental conservation and cumulative load control These values in are projected August values and are based on projections with a 1/2000 starting point.
Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak Col (10) is derived by using the formula: Col (10) = Col (2) - Col (5) - Col (6) - Col (7) - Col (8) - Col (9)
Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak Col (10) is derived by using the formula: Col (10) = Col (2) - Col.(5) - Col (6) - Col (7) - Col (8) - Col (9)

Schedule 3.3
History and Forecast of Annual Net Energy for Load - GWH: Base Case

(1) Year	(2) Total	(3) Residential Conservation	(4) C/I Conservation	(5) Retail	(6) Wholesale	(7) Utility Use & Losses	(8) Net Energy For Load	(9) Load Factor(%)

2005	110,936	450	145	109,462	1,474	7,617	110,341	67 3%
2006	112,628	554	180	111,155	1,474	7,733	111,894	66.8%
2007	114,264	659	213	112,857	1,407	7,913	113,392	66 3%
2008	115,899	765	245	114,826	1,073	8,360	114,889	66 1%
2009	117,577	874	276	116,504	1,073	8,476	116,427	65 8%
2010	119,447	919	291	118,374	1,073	8,607	118,237	65 3%

Historical Values (1991 - 2000):

Col (2) represents derived "Total Net Energy For Load w/o DSM" The values are calculated using the formula. Col.(2) = Col (8) + Col.(3) + Col.(4).
Cols. (3) & (4) are DSM values starting in January, 1988 through 1997 which contributed to the values in Cols (5) - (9)
Cols. (5) & (6) are a breakdown of Net Energy For Load in Col (2) into Retail and Wholesale
Col (9) is calculated using Col (8) from this page and Col. (2), "Total", from Schedule 3.1

Projected Values (2001 - 2010):

Col (2) represents Net Energy for Load w/o DSM values
Cols (3) - (4) are forecasted values of the reduction on sales from incremental conservation.
Cols (5) & (6) are a breakdown of Net Energy For Load in Col (2) , into Wholesale and Retail
Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented the values for Col (8) above and the values for Col (10) on Schedule 3.1

Schedule 4
Previous Year Actual and Two-Year Forecast of Retail Peak Demand and Net Energy for Load by Month

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated All values are Summer net MW

2/ Firm Capacity Imports include all firm capacity purhcases whether from out - of - state or in - state

3/ Total Capacity Available=Col (2) + Col (3) - Col (4) + Col (5)

4/ These forecasted values reflect the Most Likely forecast without DSM

5/ The MW shown represent cumulative load management capability plus incremental conservation from 1/99 - on They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based

6/ Margin (%) Before Maintenance = Col (10)/Col (9)

7/ Margin (%) After Maintenance =Col (13) /Col (9)

Schedule 7.2

* Denotes actual installed capability and total peak demand All other assumptions are projections

1/ Capacity additions and changes projected to be in-service by January 1st are considered to be available to meet Winter peak loads which are forecasted to occur during January of the "second" year indicated All values are Winter net MW

2/ Firm Capacity Imports include all firm capacity purhcases whether from out - of - state or in - state

3/ Total Capacity Available = Col (2) + Col (3) - Col (4) + Col (5)

4/ These forecasted values reflect the Most Likely forecast without DSM

5/ The MW shown represent cumulative load management capability plus incremental conservation They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based

6/ Margin (%) Before Maintenance = Col (10) /Col (9)

7/ Margin (%) After Maintenance = Col (13) /Col (9)

1)The Winter Total MW value consists of all generation additions and changes achieved by January The Summer Total MW value consists of all generation additions and changes achieved by July All other MW will be picked up in the following year This is done for reserve margin calculation

2) All MW differences are calculated based on using IRP 2000 Submittal (for the year 2000) as the base for all other years

3) Negative values for Sanford and Ft Myers reflect the existing steam units being temporarily out of service during that seasonal period for repowering efforts

Schedule 10
Status Report and Specifications of Proposed Integrated Transmission Lines

Martin: 2 CT's

(1)	Point of Origin and Termination:	Not Applicable
(2)	Number of Lines:	Not Applicable
(3)	Right-of-way	FPL Owned
(4)	Line Length:	Not Applicable
(5)	Voltage:	Not Applicable
(6)	Anticipated Construction Timing:	Start date: Not Applicable End date: Not Applicable
(7)	Anticipated Capital Investment:	Not Applicable
(8)	Substations:	Not Applicable
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Integrated Transmission Lines

Ft. Myers Repowering

(1)	Point of Origin and Termination:	From Ft. Myers – To Calusa
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	1.58 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: May 1, 2000 End date: April 1, 2001
(7)	Anticipated Capital Investment:	$354,000
(8)	Substations:	Ft. Myers and Calusa
(9)	Participation with Other Utilities:	None

(1)	Point of Origin and Termination:	From Ft. Myers – To Orange River
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	2.57 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: March 1, 2000 End date: October 1, 2000
(7)	Anticipated Capital Investment:	$706,750
(8)	Substations:	Ft. Myers and Orange River
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Integrated Transmission Lines

Sanford Repowering

(1)	Point of Origin and Termination:	From Sanford – To Poinsett
(2)	Number of Lines:	2
(3)	Right-of-way	FPL Owned
(4)	Line Length:	45 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: January 1, 2001 End date: June 1, 2001
(7)	Anticipated Capital Investment:	$20,360,000
(8)	Substations:	Sanford and Poinsett
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Integrated Transmission Lines

Ft. Myers: 2 CT's

(1) Point of Origin and Termination: From Ft. Myers GT Collector bus – To Orange River

(2) Number of Lines: 1

(3) Right-of-way FPL Owned

(4) Line Length: 2.5 miles

(5) Voltage: 230 kV

(6) Anticipated Construction Timing: Start date: January 1, 2003
End date: May 1, 2003

(7) Anticipated Capital Investment: $1,050,000

(8) Substations: Orange River and Ft. Myers GT collector bus

(9) Participation with Other Utilities: None

Schedule 10
Status Report and Specifications of Proposed Integrated Transmission Lines

Martin 5

(1)	Point of Origin and Termination:	a. From Pratt & Whitney – To Indiantown b. From Pratt & Whitney – To Ranch c. From Martin – To Indiantown
(2)	Number of Lines:	3
(3)	Right-of-way	FPL Owned
(4)	Line Length:	a. 8.45 miles b. 20.74 miles c. 11.8 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: June 1, 2004 End date: June 1, 2005
(7)	Anticipated Capital Investment:	$6,725,000
(8)	Substations:	Pratt & Whitney, Ranch, Martin, and Indiantown
(9)	Participation with Other Utilities:	None

Note:The existing lines (a & b) will be upgraded to a higher current rating. The line from Martin to Indiantown (c) will be a new circuit integrated with this project.

Schedule 10
Status Report and Specifications of Proposed Integrated Transmission Lines

Martin: Conversion of CT's into a Combined Cycle Unit

(1)	Point of Origin and Termination:	Not Available
(2)	Number of Lines:	Not Available
(3)	Right-of-way	FPL Owned
(4)	Line Length:	Not Available
(5)	Voltage:	Not Available
(6)	Anticipated Construction Timing:	Start date: Not Available End date: Not Available
(7)	Anticipated Capital Investment:	Not Available
(8)	Substations:	Not Available
(9)	Participation with Other Utilities:	None

FLORIDA PUBLIC SERVICE COMMISSION
DOCKET: 150196-EI EXHIBIT: 37
PARTY: ENVIRONMENTAL CONFEDERATION OF SOUTHWEST FLORIDA (ECOSWF) – (DIRECT)
DESCRIPTION: Karl Rábago KRR-3-B

April 1, 2002

Ms. Blanca S. Bayó, Director
Division of the Commission Clerk
and Administrative Services
Florida Public Service Commission
Capital Circle Office Center
2540 Shumard Oak Boulevard
Tallahassee, Fl 32399-0850

BY HAND DELIVERY

020000-PU

Dear Ms. Bayó,

In accordance with Chapter 186, Section 186.801 (Ten Year Power Plant Site Plans) of the Florida Statutes, enclosed are an original and fifteen (15) copies of Florida Power & Light Company's Ten-Year Power Plant Site Plan.

If you have any questions, please do not hesitate to contact me at (305) 552-4332 or Millie Gonzalez at (305) 552-2279.

Sincerely,

Anne M. Grealy
Director, Regulatory Affairs

Overview of The Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten - Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and a disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (FAC).

This Ten - Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) 2001 planning analyses and the forecasted information presented in this plan addresses the 2002 – 2011 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten - year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is data on other FPL resources, including its transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, as determined in FPL's 2001 IRP work.

Chapter IV – Environmental and Land Use Information

This chapter discusses various environmental information as well as preferred and potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional specific information which is to be included in a Site Plan filing.

Chapter VI – Summary of Required Schedules

This chapter contains Schedules 1 thru 10. It also contains FPL's Ten Year Site Plan Fact Summary.

FPL

Executive Summary

Florida Power & Light Company's (FPL) 2002 Ten - Year Power Plant Site Plan (Site Plan) addresses FPL's plans to increase its electric generation capability as part of its efforts to meet its projected incremental resource needs for the 2002 – 2011 time period.

FPL's total generation capability will significantly increase during the 2002 – 2011 time period as is shown in Table ES.1. This table also shows the resulting Summer and Winter reserve margins for FPL over this ten-year time horizon.

Table ES.1 reflects FPL's efforts to repower existing units at its Fort Myers and Sanford sites, planned changes to existing generation units (due to unit overhauls, etc.), and scheduled changes in the delivered amounts of purchased power. The table also reflects the planned additions of new generating units. Although not specifically shown in this table, FPL's approved DSM goals are assumed to be implemented on schedule.

The number of these new generating units that will be added is driven in part by the outcome of the Florida Public Service Commission docket No. 981890-EU. This docket ended with a stipulated agreement that resulted in FPL, along with Tampa Electric Company and Florida Power Corporation, switching from a minimum reserve margin planning criterion of 15% to one of 20% beginning with the Summer of 2004. As a consequence, FPL is now planning to add significantly more new generation capacity than was shown in its Site Plans filed prior to this agreement.

As shown in Table ES.1, FPL plans to add two new combustion turbines (CT's) at FPL's existing Fort Myers plant site in 2003. Also during the 2002 – 2003 time period, FPL will be completing its work to repower its two existing steam units at its Fort Myers site and two (unit Nos. 4 & 5) of its existing three steam units at its Sanford site.

FPL has also secured capacity for the time period from 2002 through early 2007 through a number of firm capacity, short-term purchases from utilities and other entities. (Please see Chapter III for a further discussion of these purchases.)

In 2005, FPL will be adding a large (1,107 Summer MW) new combined cycle (CC) unit at its existing Manatee plant site. Also in 2005, the two combustion turbines (CT's) that were added at FPL's existing Martin plant site in mid - 2001 will be converted into a 1,107 Summer MW CC unit by the addition of two additional CT's, heat recovery steam generators, and associated equipment. This conversion will add another 789 Summer MW of capability above the present capability of the existing two CT's. The additions for 2005 were selected as the best options among other FPL construction alternatives and numerous outside proposals received in response to a Request for Proposals FPL issued in August 2001.

In the 2007 through 2011 time frame, FPL tentatively plans to add 4 more CC units each with a projected Summer capability of 1,107 MW.[4] One unit will be added in each of the following years: 2007, 2009, 2010, and 2011 to meet projected load growth and to account for the scheduled end in 2010 of FPL's UPS contract with Southern Company. Sites for these four additional CC units have not yet been selected.

These planned increases in electric generation capability will allow FPL to continue to maintain system reliability and integrity at a reasonable cost.

[4] FPL's current planning studies have identified new combined cycle units as the generally preferred option to meet future load growth However, repowering of existing FPL sites remains an alternative to new construction, and FPL will continue to examine this option

Projected Capacity Changes and Reserve Margins for FPL (1)

		Net Capacity Changes (MW)		FPL Reserve Margin (%)

Table ES.1

Projected Capacity Changes and Reserve Margins for FPL

(1) Additional information about these capacity changes and resulting reserve margins is found in Chapter III of this document.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) The initial phase of the Fort Myers repowering project consists of the introduction of operational combustion turbines followed by taking existing steam units out-of-service. The second phase of repowering consists of completing the integration of the combustion turbines, heat recovery steam generators, and steam turbines.

(5) The initial phase of the Sanford repowering project consists solely of taking existing steam units # 4 and # 5 out-of-service; combustion turbine operation is not introduced at this time. The second phase of the repowering consists of integrating the combustion turbines, heat recovery steam generators, and steam turbines.

(6) These are firm capacity, shorter - term purchases. See Section I.D and III.A. for more details.

(7) The values shown reflect the schedule for the repowering of Sanford Unit # 4 that was used in FPL's 2001 resource planning work. That schedule has recently changed. Please refer to Section III.A, "Step 1" for more information. The only reserve margin effect will be to lower FPL's Winter 2003 reserve margin from 31% to 29%.

(8) The two CTs at Fort Myers are scheduled to be in-service in the Spring of 2003. Therefore, the CTs are included in the 2003 Summer reserve margin calculation and are included in the 2004 - on reserve margin included in the calculations for Summer and Winter.

(9) All new combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

(10) FPL will be determining at a later date whether to extend or replace the UPS purchases (928 MW) from Southern Company. However, for purposes of this Site Plan, FPL has assumed that the 2010 needs would be met through the addition of unsited combined cycles.

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 7.7 million people. FPL served an average of 3,935,281 customer accounts in thirty-five counties during 2001. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility-owned generation, demand side management, and interchange/purchased power.

I.A. FPL- Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville. The current generating facilities consist of four nuclear steam units, three coal units, six combined cycle units, twenty-one fossil steam units, fifty-six combustion gas turbines, and five diesel units. (Six of these fifty-six turbines are at Fort Myers and will be utilized later this year for the repowering project and another two of these fifty-six are at Martin and are planned to be used in a CT-to-CC conversion in 2005.) The location of these units is shown on Figure I.A.1.

The bulk transmission system is composed of 1,107 circuit miles of 500 Kilovolt (KV) lines (including 75 miles of 500 KV lines [two 37-1/2 mile lines] between Duval Substation and the Florida-Georgia state line, which are jointly owned with Jacksonville Electric Authority) and 2,644 circuit miles of 230 KV lines. The underlying network is composed of 1,578 circuit miles of 138 KV lines, 717 circuit miles of 115 KV lines, and 164 circuit miles of 69 KV transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 505 substations.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I A.2. In addition, Figure I.A.3. shows FPL's interconnection ties with other utilities.

Capacity Resources

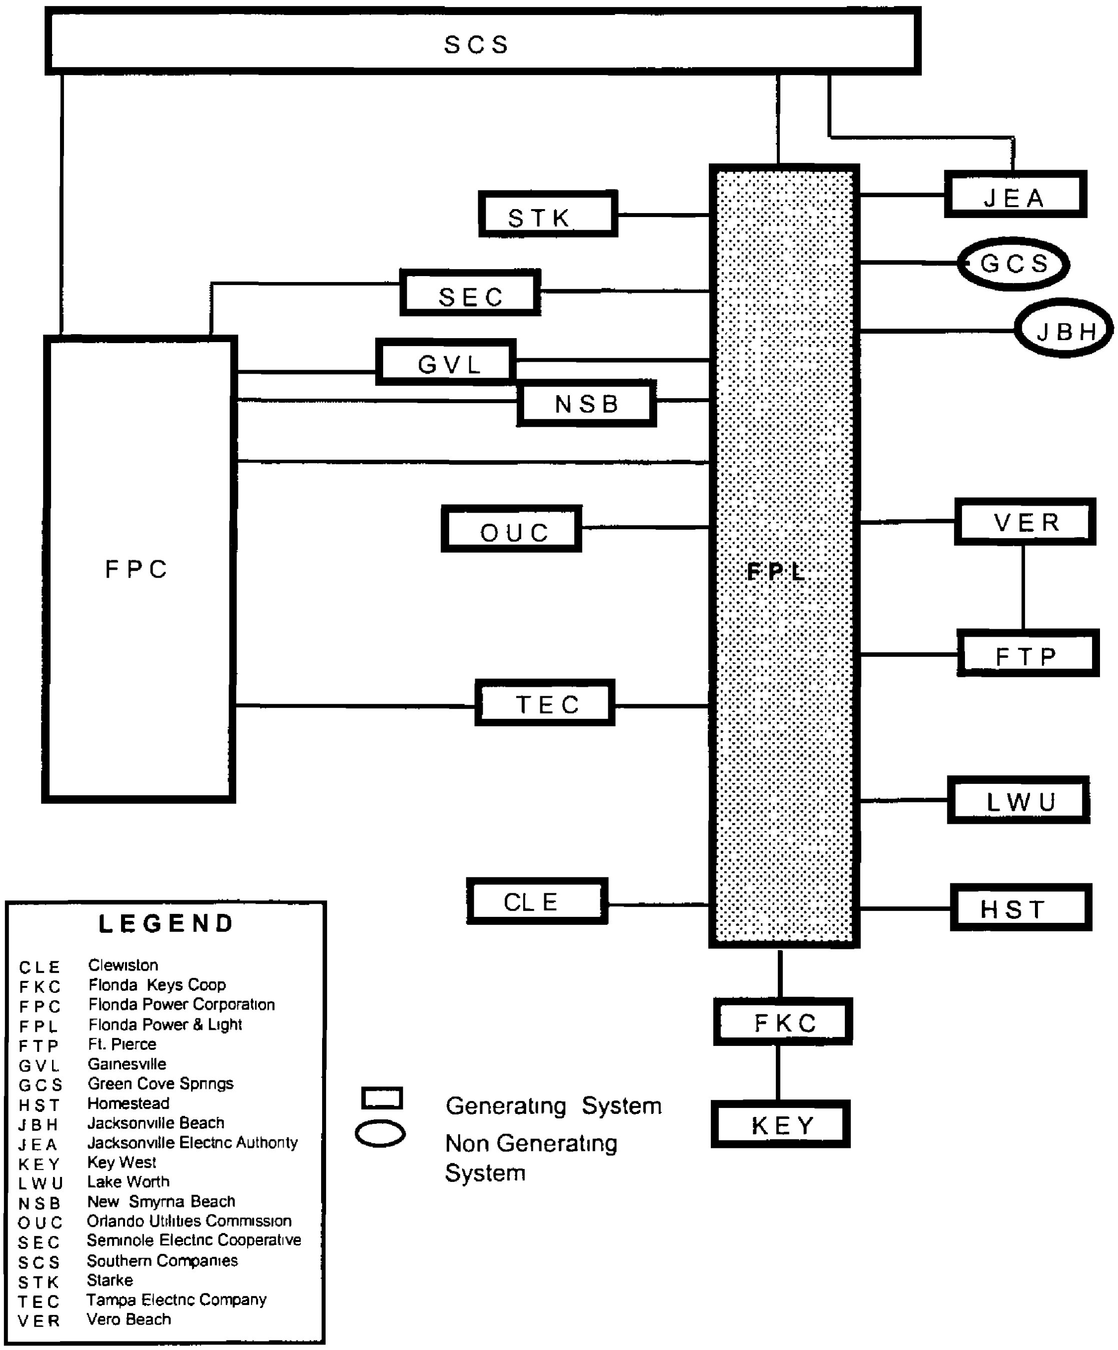

Figure I.A.3

I.B Non-Utility Generation

Non-utility generation is an important part of FPL's resource mix. FPL currently has contracts with eight cogeneration/small power production facilities to purchase firm capacity and energy. A listing of these facilities appears in Table I.B.1. In addition, FPL purchases as-available (non-firm) energy from several cogeneration facilities and small power production facilities as shown in Table I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Table I.B.2

I.C. Demand Side Management (DSM)

FPL's DSM activities continue what has been FPL's practice since 1978 of encouraging cost-effective conservation and load management. FPL's DSM efforts through 2001 have resulted in a cumulative Summer peak reduction of approximately 3,076 MW at the meter and an estimated cumulative energy saving of 19,713 GWH at the meter.

FPL's current DSM Plan was approved by the Florida Public Service Commission in late 1999 and reflects FPL's new DSM Goals for the 2000 – 2009 time frame. FPL's 2001 resource plan and the schedule for new generation additions presented in this document, are based on these approved DSM levels.

I.D. Purchased Power

Purchased power remains an important part of FPL's resource mix. FPL has a unit power sales (UPS) contract to purchase 928 MW, with a minimum of 380 MW, of coal-fired generation from the Southern Company. In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 382 MW (Summer) and 389 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Unit Nos. 1 and 2 (FPL also has an ownership interest in these units; that ownership amount is reflected in FPL's installed capacity shown on Schedule 1).

Finally, FPL has new firm capacity purchase contracts for the 2002 to early 2007 time period. These firm capacity purchase contracts are with a variety of suppliers. Table I.D.1 presents the Summer and Winter MW resulting from all firm purchased power contracts through the year 2011.

2010	928	0	389	382	0	0	1317	382
2011	0	0	389	382	0	0	389	382

Note:

(1) Total reflects total resource entitlements resulting from existing agreements between FPL, Southern Companies, JEA, and from new firm purchase agreements.

(2) Values for 2001 are actual.

(3) A discussion of these new firm capacity purchases can also be found in Section III.A.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank)

II. Forecast of Electric Power Demand

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are developed on an annual basis for resource planning work at FPL. These forecasts are a key input to the models used to develop the Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

The primary drivers to develop these forecasts are demographic trends, weather, economic conditions, and prices of electricity. In addition to these drivers, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from NOAA, and inputs from FPL's own customer service planning areas. In the area of demographics, population trends by county, plus housing characteristics such as housing starts, housing size, and vintage of homes, are assessed.

Forecasts for electric usage in the residential and commercial classes include end-use information such as appliance saturation studies, efficiencies, and intensity of energy use. In addition to these inputs, residential forecasts also make use of household characteristics such as ages of members in household, number of members in households, and income distributions.

The projections for the National and Florida economy are obtained from DRI-WEFA. Population projections for the counties served by FPL are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. In addition, FPL actively participates with local development councils and universities to obtain their assessments of the local economy, specifically in the area of expansion of new businesses and retention of the current business base. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is a key factor that affects the company's sales and peak demand. Weather variables are used in the forecasting models for energy sales and peak demand. There are two sets of weather variables developed and used in forecasting models:

1. Cooling and Heating Degree Days are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling & Heating Degree Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric heaters. A composite temperature is derived using hourly temperatures across FPL's service territory (Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained) weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree Days which are based on starting point temperatures of 72°F and 66°F, respectively. Similarly, the maximum and minimum of the composite temperature is used for the Summer and Winter peak models.

II.A. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class for the forecasting period of 2001 – 2020 and are adjusted to match the NEL forecast. The results of these sales forecasts for the years 2002 – 2011 are presented in Schedules 2.1 – 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical tool Metrix ND. The methodologies used to develop sales forecasts for each jurisdictional revenue class are outlined below.

The first five years of the forecasts were developed using monthly models for Net Energy For Load, Residential, Commercial and Industrial Sales. For the subsequent years the growth rates from the annual models are applied for Net Energy for Load and energy sales by class.

1. Residential Sales

Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted. Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, Florida per capita income, and Cooling and Heating Degree Days as explanatory variables. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be purchased in greater or lesser quantities depending upon its price. The Cooling & Heating Degree Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric heaters. The Cooling Degree Days variable is multiplied by the level of air conditioning saturations and the Heating Degree Days variable is multiplied by the level of electric heating saturations. To capture economic conditions the model includes Florida's per capita income. The degree of economic prosperity can, and does, affect residential electricity sales. For the short-term period (first five years) a similar econometric model is developed using monthly data. The monthly model is a function of the same variables such as Cooling Degree Days, Heating Degree Days, price of electricity, Florida's total personal income and a dummy variable for the months of April, May and June along with an autoregressive term.

2. Commercial Sales

The commercial sales forecast is also developed using a regression model for the long and short term. Commercial sales are a function of the following variables: Florida's commercial employment, commercial real price of electricity, Cooling Degree Days and an autoregressive term. Florida's commercial employment is used to capture the economic activity in FPL's service territory. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree Days are used to capture weather-sensitive load in the commercial sector. The first five years of the forecast are developed from a monthly model using the same explanatory variables, and for the following years, growth rates from the annual model are applied.

3. Industrial Sales

Industrial sales were forecasted through a linear multiple regression model using Florida manufacturing employment, the price of electricity and an autoregressive term as explanatory variables. Energy sales in this revenue class are primarily due to manufacturers; therefore, employment in this sector is a key variable in capturing the economic activity. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. The first five years of the forecast are developed from a monthly model using the same explanatory variables, and for the following years, growth rates from the annual model are applied.

4. Other Public Authority Sales

At present this class consists of sports fields and one government account. The forecast for this class is based on historical knowledge of its characteristics.

5. Street & Highway Sales and Railroad & Railways Sales

The forecast of Street & Highway sales are was developed using a constant use per customer, which is multiplied by the number of customers projected.

The growth in sales for Railroads & Railways are held constant since there are no plans for expansion.

6. Resales Sales

Resale (Wholesale) customers are composed of municipalities and/or electric cooperatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Contract Rate

Currently, there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of the City of Key West, Florida (City of Key West), Metro-Dade County, and FMPA. Sales to the Florida Keys are forecasted using a regression model. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor. Metro-Dade County sells 60 MW to Florida Power Corporation. Line losses are billed to Metro-Dade under a wholesale contract. The forecast is calculated based on assumptions about the magnitude of line losses, the sales monthly capacity factor, and the number of hours in a particular month. FMPA has contracted for delivery of 75 MW for the period of June 2002 through October 2007.

Total Sales

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual Net Energy for Load (NEL).

II.B. Net Energy for Load

An annual econometric model is developed to produce a Net Energy for Load (NEL) forecast. The key inputs to the model are: the price of electricity, Heating & Cooling Degree Days, and Florida Non-Agricultural Employment. The Cooling Degree Days are multiplied by cooling saturation; similarly the Heating Degree Days are multiplied by heating saturation. The monthly model is similar except the economic variable utilized is Florida's per capita income, since the model is estimated on a per customer basis. Like the sales forecasts, the first five years are obtained from the short-term model and forecasts for subsequent years are generated using the growth rates from the annual model.

Once an annual NEL forecast is obtained using the above-mentioned methodology, the results are then compared for reasonableness to the NEL forecast generated using the total sales forecast. The sales by class are then adjusted to match the NEL from the annual NEL model.

The forecasted NEL values for 2002 – 2011 are presented in Schedule 3.3 which appears at the end of this chapter. (While the forecasted value for 2001 was used during the 2001 IRP process, the form reflects the actual value for 2001.)

II.C. System Peak Forecasts

The rate of absolute growth in FPL system load has been a function of a larger customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increasing stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the Peak Forecast models to capture these behavioral relationships.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2002 - 2011 are presented in Schedules 3.1 and 3.2, as well as in Schedules 7.1 and 7.2. (While the forecasted value for 2001 was used during the 2001 IRP process, the form reflects the actual value for 2001.)

System Summer Peak

The Summer peak forecast is developed using an econometric model. The model is a per customer model that includes: the total number off FPL Summer customers, the price of electricity, real Florida income as an economic driver, and the maximum temperature as a weather variable. The model is estimated using an autoregressive term.

System Winter Peak

Like the system Summer peak model, the Winter peak model is also an econometric model. The Winter peak model is a per customer model which consists of three weather-related variables: (1) the minimum temperature on the peak day, (2) a weather term which is a product of heating saturation and minimum Winter day temperature, and (3) Heating Degree Hours for the prior day until 9:00 a.m. of the peak day. In addition, the model also has an economic term, Real Florida Income. A dummy variable, which is used to capture the effects of larger homes, is multiplied by the minimum temperature.

Monthly Peak Forecasts

Monthly peaks for the 2001 - 2020 period are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast; and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peak (Summer = April-October, Winter = November-March).

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.D The Hourly Load Forecast

Forecasted values for system hourly load for the period 2001 - 2020 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. These daily load shapes are ranked and used with forecasted monthly peaks, NEL, and calendars in developing an hourly forecast. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

Historical Values (1992 - 2001):

Cols. (2) - (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Cols. (7&9)), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.
Cols. (5) - (9) represent actual DSM capabilities starting from January 1988.
Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes GS-LC, CDR and GSD-LC.
Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: (10) = (2) -(6) -(8).

Projected Values (2002 - 2011):

Cols. (2) - (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2001 are incorporated into the forecast.
Cols. (5) - (9) represent all incremental conservation and cumulative load control. These values are projected August values and are based on projections with a 1/2001 starting point.
Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: (10) = (2) - (5) - (6) - (7) - (8) - (9).

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990's and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of potential new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2001 planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

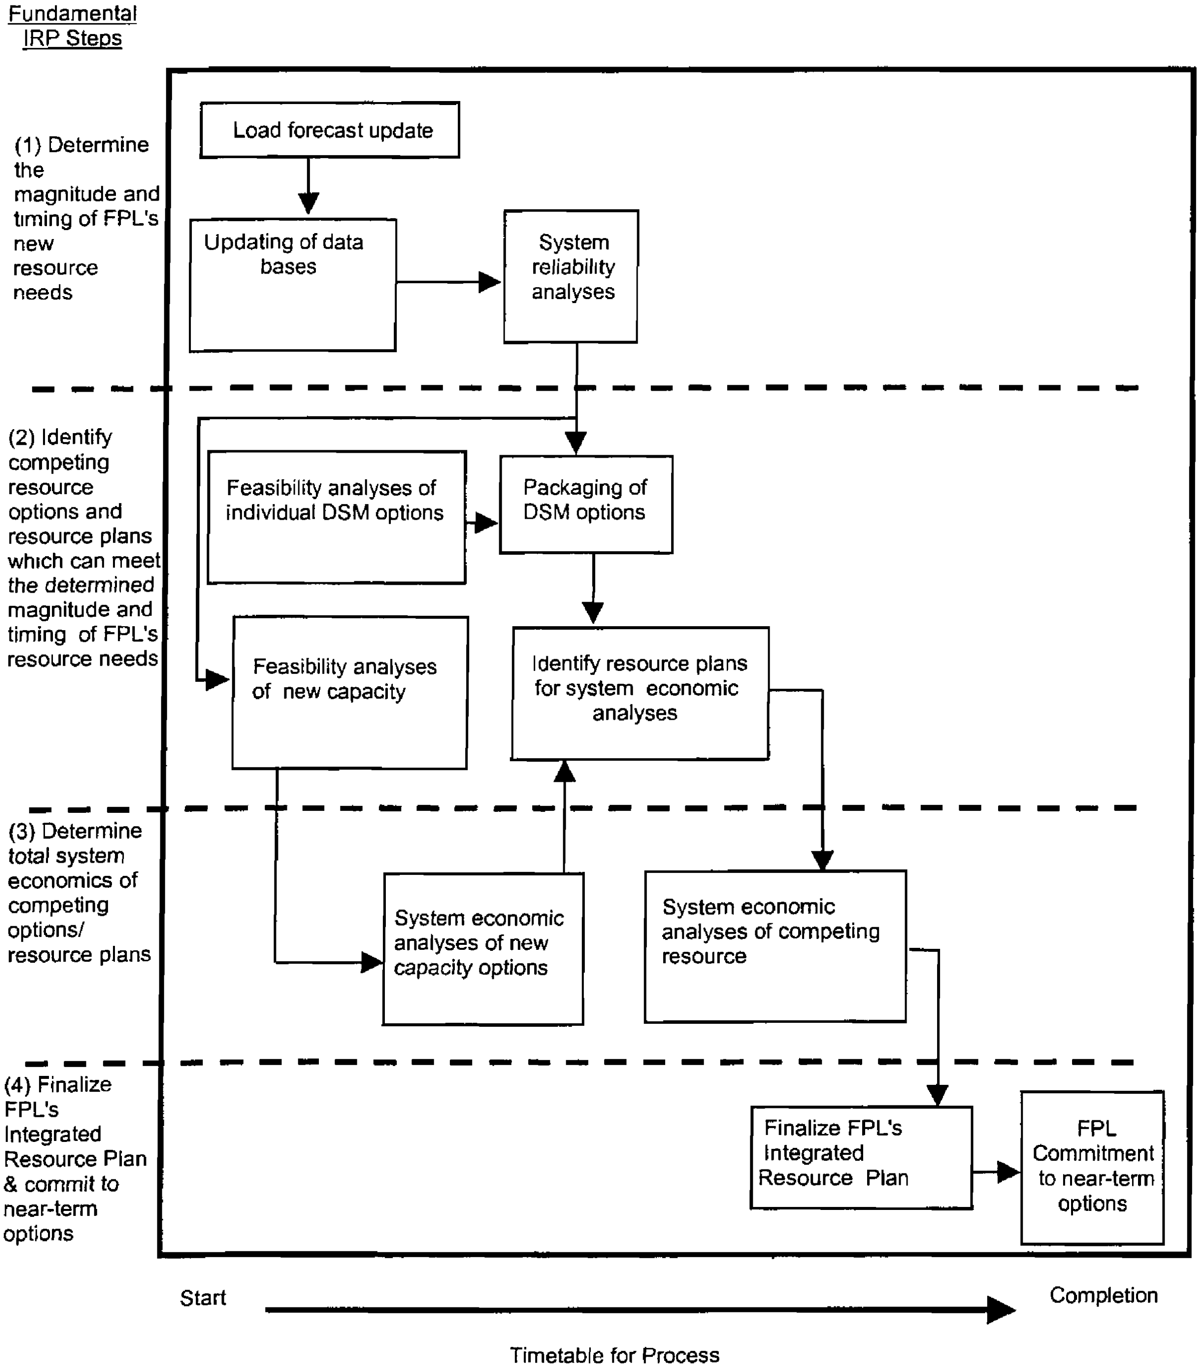
Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans;

Step 3: Determine the economics for the total utility system with each of the competing options and resource plans; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

Overview of FPL's IRP Process



(Normal time period: approx. 6-7 months)

Figure III.A.1

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps – determining the magnitude and timing of FPL's resource needs – is essentially a determination of how many megawatts (MW) of load reduction, new capacity, or a combination of both load reduction and new capacity options are needed. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a reliability assessment for the utility system.

Step 1 starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information which is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. Three assumptions made by FPL during its 2001 IRP work involved near-term construction capacity additions, near-term firm capacity purchase additions, and long-term DSM implementation.

The first of these assumptions included FPL's announced plans to add near-term capacity through various construction projects. These construction projects include the repowering of several existing units and the addition of several new CT's. FPL committed in 1998 to repower both existing steam units at its Fort Myers plant site and two of the three existing steam units at its Sanford plant site. These two repowering efforts will add significant capacity to FPL's system and will greatly increase the efficiency of the capacity at those two sites. The repowered Fort Myers capacity is scheduled to come in-service by the Summer, 2002. CT's, which are components of the repowering effort, began coming in-service at Fort Myers in late 2000 and through their initial operation in a stand-alone mode have already increased FPL's system capacity. A somewhat different schedule is planned for the two Sanford units which will be repowered. Both of these units will be repowered without the combustion turbine components coming in-service during the process. Sanford Unit # 5 came out-of-service in the Fall, 2001, and will return fully repowered by Summer, 2002. Sanford Unit # 4 was projected to come out-of-service in the Spring, 2002, and was assumed to return fully repowered at the end of 2002. As a result of this commitment, FPL assumed that these capacity additions resulting from the Fort Myers and Sanford repowerings were a "given" in its 2001 resource planning work.

Another part of FPL's construction capacity addition assumption was its previously announced (in last year's Site Plan) decision to add two new CT's 2003 at FPL's existing Fort Myers site. FPL's 2001 resource planning work assumed that these new CT construction capacity additions would also be a "given".

The second of these assumptions involved a decision which was made during FPL's 2000 resource planning work to secure an amount of capacity for the next few years through firm capacity, short-term purchases. These firm capacity purchases are from a combination of utility and independent power producers. These capacity purchases were not finalized at the time FPL filed last year's (2001) Site Plan, but were finalized later in 2001. The total capacity and duration of these purchase totals are both greater than projected in last year's Site Plan. The annual total capacity values for these purchases are presented in Table I.D.1. These purchase amounts are also assumed as a "given" in FPL's 2001 resource planning work.

The third of these assumptions involved DSM. Since 1994, FPL's resource planning work has used the DSM MW called for in FPL's approved DSM goals as a "given" in its analyses. This was again the case in FPL's 2001 planning work as its recently approved new DSM goals through the year 2009 were taken as a given.

The first place in which these assumptions and much of the other updated information and assumptions are used is the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 15% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 days/year criteria. Both of these criteria are commonly used throughout the utility industry. The reserve margin criterion increases from 15% to 20% starting in mid - 2004 due to a voluntary agreement reached among FPL, FPC, and TECO, and accepted by the FPSC in the FPSC's Docket No. 981890-EU.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analyses. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple calculation can be performed on a spreadsheet. It provides an indication of how well a generating system can meet its native load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as: unit reliability; unit numbers and sizes (i.e., two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time); and the value of being part of an interconnected system.

Therefore, probabilistic methodologies have been used to provide additional information on the reliability of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss-of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does reserve margin analysis. Reserve margin analyses are typically carried out on a spreadsheet. The more complicated LOLP analyses are carried out using the Tie Line Assistance and Generation Reliability (TIGER) model.

The end result of the first fundamental step of resource planning is a projection of how many MW are needed to maintain system reliability and of when the MW are needed. This information is used in the second fundamental step: identifying resource options and resource plans which can meet the determined magnitude and timing of FPL's resource needs

Step 2: Identify Resource Options and Plans Which Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analyses of new capacity options are carried out to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction / permitting schedules, and operating parameters and costs.

The individual new capacity options are then "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using dynamic programming techniques.

In recent years, FPL's analysis of new capacity options in its annual resource planning work has included only FPL construction options. The earliest date new capacity options were projected to be needed was in 2005. Prior to the 2001 planning cycle, the 2005 date was distant enough so that no actual construction/purchase decision was needed. However, in 2001, that was no longer the case. Furthermore, the type of new units FPL had been projecting for construction (combined cycle units) are among those addressed in the Florida Public Service Commission's "Bidding Rule" and thus require the issuance of a Request for Proposals (RFP) for meeting this capacity need.

FPL issued a Capacity RFP in mid – August of 2001. The RFP sought 1,150 MW of additional capacity by mid – 2005 and another 600 MW of additional capacity by mid – 2006. Fifteen (15) developers submitted one or more proposals in response to the RFP. In all, 81 proposals from these developers were evaluated along with 13 FPL construction options. Consequently, a much larger than usual number of generation options were evaluated in FPL's 2001 planning work.

At the conclusion of the second fundamental resource planning step in 2001, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs were identified. These resource plans were then compared on an economic basis.

Step 3: Determining the Total System Economics:

At the completion of fundamental Steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for comparing the system economics of these resource plans. FPL combines the resource options into resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI) and Stone & Webster Management Consultants, Inc. The EGEAS model is also used to perform the basic economic analyses of the resource plans.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of the competing resource plans is the competing resource plans' impact on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases such as existed for FPL's 2001 planning work in which the DSM contribution was taken as a "given" and the only competing options were new generating units or purchases, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, for FPL's 2001 resource planning work, the competing options and plans were evaluated on a present value system revenue requirement basis.

The basic economics analyses carried out with the EGEAS model focus on the capital and operating costs of new capacity options plus the impact these new capacity options have on FPL's system fuel costs. In FPL's 2001 analyses, three other costs were also evaluated. These three additional costs were: generator startup costs, transmission integration costs, and equity penalty costs. Once these three costs were calculated for the competing resource plans, they were added to the EGEAs costs to derive total costs.

In addition to FPL's own work that was carried out with the EGEAS model, an independent evaluator, Sedway Consulting, performed its own analyses of the outside proposals and FPL construction options. Sedway Consulting utilized its won Response Surface Model (RSM) to perform its basic economic analyses, then added in the generator startup costs, transmission integration costs, and equity penalty costs utilized by FPL. Finally Sedway Consulting used its RSM-derived estimate of residual benefits for FPL's construction options to derive its own total cost projections for the competing resource plans. Sedway Consulting's analyses came to the same conclusion as FPL analyses: FPL's Martin Conversion project and Manatee CC unit were the most cost-effective alternatives.

At the conclusion of the analyses carried out in Step 3, a determination of FPL's preferred resource plan was made.

Step 4: Finalizing FPL's 2001 Resource Plan

The results of the previous three fundamental steps' activities were evaluated by FPL management and a decision was made as to what FPL's 2001 resource plan would be. This plan is presented in the following section.

This evaluation focused both on the economics of the competing resource plans and on various non – price factors that essentially address risks associated with these plans. Both the economics and risk considerations favored the construction of the Manatee and Martin units.

III.B Incremental Resource Additions

FPL's projected incremental generation capacity additions/changes for 2002 through 2011 are depicted in Table III.B.1. (The planned DSM additions are shown separately in Table III.C.1.) These capacity additions/changes will result from a variety of actions including: changes to existing units (which are typically achieved as a result of plant component replacements during major overhauls), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, repowering of existing units, projected construction of new units, and conversion of CT's into CC's.

As shown in Table III.B.1, the bulk of the capacity additions are made up of the following items: the repowering of both existing steam units at FPL's Fort Myers site by Summer, 2002; a similar repowering of FPL's Sanford Unit # 5 and # 4 projected by the Summer, 2002, and the end of 2002, respectively; the construction of two new CT's by mid – 2003, the conversion of two CT's into a larger CC unit in 2005 at FPL's Martin site; the addition of a new CC unit also in 2005 at FPL's Manatee site, new firm capacity, shorter-term purchases through early 2007; and the construction of four additional unsited CC units in the 2007 through 2011 time frame.[1] (Note that during FPL's 2001 resource planning work the projected schedule for repowering Sanford Unit # 4 was for the unit to come off-line in March, 2002 and return to service in December, 2002. These dates have recently been changed to August, 2002 and June, 2003, respectively. This schedule change has no effect on the 2002 Summer reserve margin shown in this document, but will lower FPL's Winter 2003 reserve margin from approximately 28% to 26%.)

The number of CC units which are projected to be built in FPL's 2002 Site Plan has decreased compared to the number of CC units shown in the 2001 Site Plan. This is due to the fact that the projected capacity of the new CC units has approximately doubled (i.e., approximately 1,100 MW from 550 MW) from last year's projections due to a preferred new design approach that utilizes 4 CT's instead of 2 CT's for each CC unit.

As first presented in last year's site plan, this site plan also shows capacity additions needed in 2010 to replace approximately 930 MW of firm capacity purchases from the Southern Company that are scheduled to end in 2010. The end of these purchases requires FPL to replace this capacity, as well as to meet projected load growth for 2010, in a way which meets a minimum 20% reserve margin requirement. While FPL has not yet determined whether it would extend or replace these purchases, or build new capacity to meet its needs, for purposes of this Site Plan it was assumed that the 2010 needs would be met through the addition of unsited CC units.

[1] FPL's current planning studies have identified new combined cycle units as the generally preferred option to meet future load growth However, repowering of existing FPL sites remains an alternative to new construction, and FPL will continue to examine this option.

Projected Capacity Changes for FPL [1]			
		Net Capacity Changes (MW)	
		Winter [2]	***Summer*** [3]
2002	Fort Myers Repowering:Second Phase [4]	(1)	35
	Sanford Repowering # 5: Initial Phase [5]	(390)	---
	Sanford Repowering # 5: Second Phase [5]	---	567

Table III.B.1

Projected Capacity Changes for FPL

Note:

(1) Additional information about these capacity changes and resulting reserve margins is found in Chapter III of this document.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) The initial phase of the Fort Myers repowering project consists of the introduction of operational combustion turbines followed by taking existing steam units out-of-service. The second phase of repowering consists of completing the integration of the combustion turbines, heat recovery steam generators, and steam turbines.

(5) The initial phase of the Sanford repowering project consists solely of taking existing steam units # 4 and # 5 out-of-service; combustion turbine operation is not introduced at this time. The second phase of the repowering consists of integrating the combustion turbines, heat recovery steam generators, and steam turbines.

(6) These are firm capacity, short - term purchases. See Section I.D and III.A. for more details.

(7) The values shown reflect the schedule for the repowering of Sanford Unit # 4 that was used in FPL's 2001 resource planning work. That schedule has recently changed. Please refer to Section III.A, "Step 1" for more information. The only reserve margin effect will be to lower FPL's Winter 2003 reserve margin from 31% to 29%.

(8) The two CT's at Fort Myers are scheduled to be in-service in the Spring of 2003. Therefore, the CT's are included in the 2003 Summer reserve margin calculation and are included in the 2004 - on reserve margin included in the calculations for Summer and Winter.

(9) All new combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

(10) FPL will be determining at a later date whether to extend or replace the UPS purchases (928 MW) from Southern Company. However, for purposes of this Site Plan, FPL has assumed that the 2010 needs would be met through the addition of unsited combined cycles.

III.C Demand Side Management (DSM)

1. FPL's Current DSM Programs

FPL's currently approved DSM programs are summarized as follows:

Residential Conservation Service: This is an energy audit program which is designed to assist residential customers in understanding how to make their homes more energy-efficient through the installation of conservation measures/practices.

Residential Building Envelope: This program encourages the installation of energy-efficient ceiling insulation in residential dwellings that utilize whole-house electric air-conditioning.

Duct System Testing and Repair: This program encourages demand and energy conservation through the identification of air leaks in whole-house air conditioning duct systems and by the repair of those leaks by qualified contractors.

Residential Air Conditioning: This is a program to encourage customers to purchase higher efficiency central cooling and heating equipment.

Residential Load Management (On Call): This program offers load control of major appliances/household equipment to residential customers in exchange for monthly electric bill credits.

New Construction (BuildSmart): This program encourages the design and construction of energy-efficient homes that cost-effectively reduce coincident peak demand and energy consumption.

Business Energy Evaluation: This program encourages energy efficiency in both new and existing commercial and industrial facilities by identifying DSM opportunities and providing recommendations to the customer.

Commercial/Industrial Heating, Ventilating, and Air Conditioning: This program encourages the use of high-efficiency heating, ventilating, and air conditioning (HVAC) systems in commercial/industrial facilities.

Commercial/Industrial Efficient Lighting: This program encourages the installation of energy-efficient lighting measures in commercial/industrial facilities.

Business Custom Incentive: This program encourages commercial/industrial customers to implement unique energy conservation measures or projects not covered by other FPL programs.

Commercial/Industrial Load Control: This program reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

Commercial/Industrial Demand Reduction: This program (which started in 2001) is similar to the Commercial/Industrial Load Control mentioned above by continuing the objective to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits.

Commercial/Industrial Building Envelope: This program encourages the installation of energy-efficient building envelope measures such as window treatments and roof/ceiling insulation for commercial/industrial facilities.

Business On Call: This program offers load control of central air conditioning units to both small, non-demand-billed and medium, demand - billed commercial/industrial customers in exchange for monthly electric bill credits.

2. Research and Development

FPL's DSM Plan continues to support research and development activities. Historically, FPL has performed extensive DSM research and development. FPL will continue such activities not only through its Conservation Research and Development program, but also through individual research projects. These efforts will examine a wide variety of technologies which build on prior FPL research where applicable and will expand the research to new and promising technologies as they emerge.

Conservation Research and Development Program

FPL's Conservation Research and Development Program is designed to evaluate emerging conservation technologies to determine which are worthy of pursuing for program development and approval. FPL has researched a wide variety of technologies and from that research has been able to develop new programs such as Residential New Construction, Commercial/Industrial Building Envelope, and Business On Call.

Low Income Weatherization Retrofit Project

This R&D project is investigating cost-effective methods of increasing the energy efficiency of FPL's low - income customers. The research project addresses the needs of low - income housing retrofits by providing monetary incentives to various housing authorities including weatherization agency providers (WAPS), and non-weatherization agency providers (non-WAPS). These incentives are used by the housing authorities to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting. FPL either conducts a home energy survey, trains housing authority employees to perform FPL home energy surveys, accepts the National Energy Audit (NEAT) (as supplemented to capture water heating recommendations not included in the NEAT audit), or approves similar FPL - approved audits conducted by weatherization providers to determine the need for energy efficient retrofit measures for each home. FPL has designed the project so as to minimize extra work for the retrofit housing authorities.

Photovoltaic Research, Development and Education Project

Photovoltaic (PV) roof-tile systems are a relatively new technology which directly replaces existing roofing materials such as shingles and standing-rib roofing with PV materials. These PV materials have the same water - proofing characteristics as conventional roofing materials. This project is consistent with the Federal Government's Million Solar Roofs initiative. However, based on FPL's research to - date, a primary hurdle to the physical installation of PV systems, whether roofing materials or flat plate modules, is the lack of awareness, understanding, and acceptance by local building officials. For the most part, these officials are unclear about how these systems work and how to address these systems as part of the building, permitting, and inspection process. This creates barriers toward the use of this technology.

Green Energy Project

FPL finished an R&D project addressing customer acceptance of green energy where donations were used as the funding mechanism for the purchase and installation of utility - grid connected PV systems. This project raised in excess of $89,500 and a 10.1 kW (dc) PV system has been constructed at FPL's Martin power plant site.

FPL is now investigating potential customer acceptance of green pricing rates in its Green Energy Project. Under this project, FPL is examining the feasibility of purchasing electric energy generated from new renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable resources. Participating customers would then be charged higher "green" electric rates for utilizing electric energy derived from these sources.

FPL's Request for Proposals (RFP) solicitation previously mentioned in Section III.A. also included a separate request for proposals that would supply energy only (MWH) from new, renewable energy sources. Several proposals were received in response to the RFP and the proposals are now being evaluated. This evaluation will determine whether the proposals are suitable for providing renewable energy that could be offered in a Green Energy program. A decision on this is expected by mid – 2002.

Real-Time Pricing

Although not part of FPL's approved DSM Plan, FPL continues to research new conservation/efficiency options such as Real-Time Pricing. This option is an experimental service offering for large C/I customers designed to evaluate customer load response to hourly, marginal cost-based energy prices provided on a day-ahead basis.

3. FPL's DSM MW Goals

FPL's DSM implementation plan is designed to meet currently approved DSM Goals for 2000 – 2009. The combined total residential and commercial/industrial Summer MW reduction values from FPL's DSM Goals for 2000 – 2009 are presented in Table III.C.1. FPL has already implemented approximately 2,790 MW at the meter of DSM through 2001.

FPL's Summer MW Reduction Goals for DSM
(At the Meter)

Year	Cumulative Summer MW
2000	122
2001	200
2002	269
2003	339
2004	410
2005	484
2006	554
2007	625
2008	697
2009	765

Table III.C.1

III.D Independent Power Producers Generation Additions

As previously mentioned in Section III.A, FPL has entered into a number of new firm capacity, shorter - term purchases that extend through early 2007. The capacity supplied by these purchases are summarized in Table I.D.1. All but 50 MW of these purchases are from independent power producers.

Tables I.B.1 and I.B.2 present the previously contracted cogeneration/small power production facilities which are addressed in FPL's resource planning.

III.E Transmission Plan

The 2002 - 2011 transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV and 500 kV bulk transmission lines.

List of Proposed Power Lines
2002 – 2011

OWNER	LINE TERMINAL (FROM)	LINE TERMINAL (TO)	NET NEW CIRCUIT MILES	COMMERCIAL IN-SERVICE DATE (Mo/YR)	NOMINAL OPERATING VOLTAGE (KV)
FPL	Fort Myers GT's	Orange River	2.56	Mar-02	230
FPL	Greynolds (Aventura)	Laudania	6.70	Mar-02	230
FPL	Brevard	Malabar #2	25.79	Jun-02	230
FPL	Brevard	Malabar #3	25.79	Jun-02	230
FPL	Broward-Corbett	Marymount-Yamato	0.25	Jun-03	230
FPL	Broward-Corbett	Rainberry-Yamato	10.50	Jun-03	230
FPL	Broward-Goolsby	Yamato	2.50	Jun-03	230
FPL	Cortez	Johnson	11.00	Jun-03	230
FPL	Delmar	Yamato	2.00	Jun-03	230
FPL	Duval-Kingsland	Yulee-Oneil	6.50	Jun-03	230
FPL	Midway	Turnpike	2.00	Jun-03	230
FPL	Charlotte-Laurelwood	Coast-Peachland	6.70	Dec-03	230
FPL	Andytown	Pennsuco	2.00	Jun-04	230
FPL	Dade	Overtown	11.00	Jun-04	230
FPL	Indiantown	Martin #2	11.80	Jun-05	230
FPL	Conservation	OaklandPark	13.00	Jun-07	230
FPL	Conservation	Levee	36.00	Jun-08	500

Table III.E.1

In addition, there will be transmission facilities needed to connect FPL's projected capacity additions to the system transmission grid. These transmission facilities for the projected capacity additions at FPL's existing Fort Myers, Sanford, Martin, and Manatee sites are described below. Since the projected capacity additions for 2007 through 2011 are as-yet unsited, no transmission facilities information is provided. This information will be provided in future Site Plan documents once a site is selected.

III.E.1 Transmission Facilities at Fort Myers

The transmission work required for the repowering capacity addition at Fort Myers is as follows:

I. Substation:

1. Substation work is complete.

II. Transmission:

1. Transmission work is complete.

III.E.2 Transmission Facilities at Sanford

The transmission work required for the repowering capacity additions at Sanford is as follows:

I. Substation:

1. Substation work is complete.

II. Transmission:

1. Upgrade the Volusia #2 transmission line to 1475 Amps.

III.E.3 Transmission Facilities at Fort Myers

The transmission work required for the two new CT units at Fort Myers is projected to be as follows:

I. Substation:

1. Build one collector bus with 2 breakers each to connect 2 CT's on each one. Add another breaker to the collector bus to connect the start-up transformer.
2. Add the two main step-up transformers (200MVA/each), one for each CT.
3. Add the start-up transformer.
4. Disconnect the existing Fort Myers GT collector bus from the Fort Myers 230kV switchyard.
5. Add two breakers at Orange River 230 kV substation to connect the new line from the Fort Myers GT collector bus.
6. Connect the new Fort Myers collector bus to the Fort Myers 230kV switchyard.
7. Connect the Fort Myers collector bus to the Fort Myers 230kV switchyard.
8. Replace 4 breakers at the existing Fort Myers 230 kV switchyard.
9. Add relay and other protective equipment at Fort Myers and Orange River substations.

II. Transmission:

1. Build a new 230 kV line from the Fort Myers GT collector bus to Orange River (approximately 2.57 miles) similar to the existing circuits which are bundle 2-1431 ACSR 2580 Amps (1028 MVA) each.
2. Add protection and control equipment for the new line.

III.E.4 Transmission Facilities at Manatee

The transmission work required for the new combined cycle unit at Manatee is projected to be as follows:

II. Substation:

1. Build new collector yard containing two collector busses with 7 breakers to connect the four CT's, one ST, and the two start-up transformers.
2. Construct two string busses to connect the collectors and main switchyard.
3. Add five main step-up transformers (4-200MVA, 450MVA) one for each CT, and one for the ST.
4. Add the start-up transformers.
5. Add two breakers in bay # 6 to connect the collector bus at the Manatee switchyard.
6. Add three breakers in bay # 5 at the Manatee switchyard to connect the other collector bus and a new transmission line to Johnson # 2.
7. Add relays and other protective equipment.
8. Upgrade 230kV circuit breakers to 2 cycle Independent Pole breakers at Manatee switchyard.
9. Add a new line terminal at Johnson.

II. Transmission:

1. Construct 230kV Manatee-Johnson # 2 transmission line.
2. Add protection and control equipment for the new lines.
3. Upgrade the Johnson- JohnsonTap 138kV transmission line to 656 Amps.
4. Upgrade the Charlotte- Fort Myers 230kV transmission line to 1081 Amps.

III.E.5 Transmission Facilities at Martin

The transmission work required for the Martin Conversion project (convert the existing two CT's to a new four -on- one combined cycle unit) is projected to be as follows:

I. Substation:

1. Build new collector yard containing one collector buss with 4 breakers each to connect the two CT's, one ST, and the start-up transformer.
2. Add three main step-up transformers (2-200 MVA, 450MVA) one for each CT, and one for the ST.
3. Add the start-up transformer.
4. Add two breakers in bay #3 to connect the collector bus in the main switchyard.
5. Add relays and other protective equipment.
6. Install phase reactors and string buss in main switchyard to limit fault current.
7. Add breaker in bay #7 (7WE) for new Indiantown #2 transmission line. Tap existing 69kV auto-transformer off east 230kV operating buss.
8. Add breaker in Bay #3 (3WS) at Indiantown Substation for Martin line.
9. Create new bay 1a. Add breakers 1aWM, 1aWS for Indiantown-Bridge#2 line at Indiantown Substation.
10. Create new bay#1 at Bridge Substation with breakers 1WW and 1WM. Add breakers 2WW and 2WE to convert station configuration from ring buss.
11. Construct one string bus to connect the collector and main switchyard.

II. Transmission:

1. Construct 230kV Martin-Indiantown #2 transmission line.
2. Construct 230kV Indiantown – Bridge #2 transmission line.
3. Various OHGW replacements due to increased fault current.
4. Upgrade the Ranch - Marlin(2005) 230kV transmission line to 2052 Amps.
5. Upgrade the Cedar - Marlin (2005) 230kV transmission line to 1965 Amps. (Note that this line is necessary only if both Manatee & Martin are constructed and it is presented here for ease of presentation.)

III.F. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various technologies.

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970's in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities on both a daily and annual basis in Florida. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10 kilowatt (KW) system was placed into operation in 1984. The testing of this PV installation was completed, and the system was removed in 1990 to make room for substation expansion.

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed on the following page).

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first and only utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was not cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980's, FPL introduced another renewable energy program. FPL's Passive Home Program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. Complete designs and construction blueprints for 6 passive homes were created by 3 Florida architectural firms with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building code. This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test may be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, as well as customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

More recently, FPL has analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach does not require all of its customers to bear PV's high cost, but allows customers who are interested in facilitating the use of renewable energy the means to do so. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund, which FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid. Thus, when sunlight is available at this site(s), the PV-generated electricity displaces an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach, which has been termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's initial efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL initiated the effort in 1998 and received approximately $89,000 in contributions which significantly exceeded the goal of $70,000. FPL has purchased the PV modules and installed them at FPL's Martin plant site.

As previously discussed, FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was the Green Energy Project which is a second, different attempt to implement the basic Green Pricing approach. Under this project FPL would purchase electric energy generated from new renewable resources. The project would offer to supply to FPL's electrical grid the equivalent of all, or part of, a customer's monthly Kwh usage with electricity generated from new renewable resources, with the remaining portion of that load being served by the Company's conventional generating facilities. Participants would be residential (and possibly commercial) customers who would pay higher ("green" rates) for electricity provided from these renewable sources. As discussed in Section III.1, FPL issued a Request for Proposals (RFP) in 2001 to solicit proposals to supply energy only (MWH) from new renewable sources. Proposals have been received and are now being evaluated. Program feasibility is also being assessed.

The second effort initiated in 2000 is FPL's Photovoltaic Research, Development and Education Project. This demonstration project's objectives are to increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks as well as the energy capabilities of roof tile PV systems, and assess the homeowner's financial benefits and costs of PV roof tile systems for our customers.

Finally, FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy, and as-available energy, have been purchased by FPL from these developers. (Please refer to Tables I.B.1 and I.B.2).

III.G FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980's, FPL relied primarily on a combination of oil, natural gas, and nuclear energy to generate electricity. In 1986, coal was first added to the fuel mix, allowing FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources have been added with the partial acquisition (76%) of Scherer Unit # 4. In 1997, petroleum coke was added to the fuel mix as a blend stock with coal at the St. Johns River Power Park.

2. Fuel Price Forecasts

FPL's long-term oil price forecast assumes that worldwide demand for petroleum products will grow moderately throughout the planning horizon. Non-OPEC crude oil supply is projected to increase as new and improved drilling technology and seismic information will reduce the cost of producing crude oil and increase both recovery from existing fields and new discoveries. However, the rate of increase in non-OPEC supply is projected to be slower than that of petroleum demand, resulting in an increase in OPEC's market share throughout the planning horizon. As OPEC gains market share, prices for petroleum products are projected to increase.

FPL's natural gas price forecast assumes that domestic demand for natural gas will grow throughout the planning horizon, primarily due to increased requirements for electric generation. Domestic natural gas production will increase as new and improved drilling technology and seismic information will reduce the cost of finding, developing, and producing natural gas fields. The rate of increase in domestic natural gas production is assumed to be slower than that of demand, with the balance being supplied by increased Canadian and liquefied natural gas (LNG) imports. As demand for natural gas in Florida grows, it is anticipated that based on natural gas users' commitments, the Florida Gas Transmission (FGT) pipeline system will be augmented/expanded. This anticipated expansion of FGT's pipeline, combined with the new Gulfstream pipeline, should result in sufficient gas for FPL's continued needs.

1)The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by July All other MW will be picked up in the following year This is done for reserve margin calculation

2) All MW differences are calculated based on using IRP 2001 Submittal (for the year 2001) as the base for all other years

3) The values shown reflect the schedule for the repowering of Sanford Unit # 4 that was used in FPL's 2001 resource planning work. That schedule has recently changed Please refer to Section III A, "Step 1" for more information.

4) Negative values for Sanford and Ft Myers reflect the existing steam units being temporarily out of service during that seasonal period for repowering efforts

Schedule 8
Planned And Prospective Generating Facility Additions And Changes (Cont.)

Status Report and Specifications of Proposed Transmission Lines

Fort Myers Repowering

The transmission line work for this project has been completed.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Sanford Repowering

The transmission line work for this project has been completed.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Ft. Myers: 2 CT's

(1)	Point of Origin and Termination:	From Ft. Myers GT Collector bus – To Orange River
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	2.5 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: January 1, 2003 End date: May 1, 2003
(7)	Anticipated Capital Investment:	$1,050,000
(8)	Substations:	Orange River and Ft. Myers GT collector bus
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Manatee CC Unit

(1)	Point of Origin and Termination:	Manatee – Johnson
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	18 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: June 1, 2004 End date: June 1, 2005
(7)	Anticipated Capital Investment:	$12,700,000
(8)	Substations:	Manatee and Johnson
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Martin CT – to - CC Conversion

(1)	Point of Origin and Termination:	Martin – Indiantown #2
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned & New acquisitions
(4)	Line Length:	12.9 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBA End date: TBA
(7)	Anticipated Capital Investment:	$9,400,000
(8)	Substations:	Martin 230kV and Indiantown
(9)	Participation with Other Utilities:	None

(1)	Point of Origin and Termination:	Indiantown – Bridge
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	10.0 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBA End date: TBA
(7)	Anticipated Capital Investment:	$10,300,000
(8)	Substations:	Indiantown and Bridge
(9)	Participation with Other Utilities:	None

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in our service area is continuing, which heightens competition for air, land, and water resources which are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among electric utilities for our commitment to the environment. Our environmental leadership has been heralded by many outside organizations. For example, FPL was recently ranked first out of 30 major electric utilities surveyed in an environmental assessment conducted by Innovest, an independent advisory group. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. We also received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" for our emission-reducing "repowering" projects at our Fort Myers and Sanford plants. In addition, FPL has been recognized by numerous federal and state agencies for our innovative endangered species programs which include such species as manatees, crocodiles and sea turtles.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define the Company's position. This statement reflects how FPL incorporates environmental values into all aspects of the Company's activities and serves as a framework for new environmental initiatives throughout the Company. The FPL environmental statement further establishes a long-term direction of environmental responsibility for the Company. FPL's Environmental Statement is:

> It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:

- Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
- Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
- Encourage the wise use of energy to minimize the impact on the environment.
- Communicate effectively on environmental issues.
- Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program which is discussed below. Other components include: written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident/emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to: evaluate environmental performance, verify compliance with Company policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to: 1) facilitate management control of environmental practices; and, 2) assess compliance with existing environmental regulatory requirements and Company policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and public education. Some of FPL's 2001 environmental outreach activities are noted in Table IV.E.1.

2001 FPL Environmental Outreach Activities *

Site	Activity	# of Participants (approx.)
St. Lucie Plant	Turtle Beach Nature Trail Visitation	2,000
Riviera Plant & Fort Myers Plant	Manatee Awareness Activities	155,000
St. Lucie Plant	Turtle Walk Participation	802
St. Lucie Plant	FPL Energy Encounter	28,000
Not applicable	Inquiries - 800 enviromental information line and e-mails	3,800
Martin Plant	Barley Barber Swamp Visitation	2,200

Table IV.E.1

* A reduction in attendance at some of these facilities was observed due to changes in operation as a result of the events of September 11, 2001.

IV.F Preferred And Potential Sites

Based upon its projection of future resource needs, FPL has identified preferred and potential sites for future generation additions. These preferred and potential sites are discussed in separate sections below.

IV.F.1 Preferred Sites

FPL has identified four preferred sites: the existing Fort Myers plant site, the existing Sanford plant site, the existing Martin plant site, and the existing Manatee plant site. These four sites are currently the expected known locations for capacity additions that FPL projects to make during the 2002 – 2005 period. (Other capacity additions, in the form of new combined cycle units, are projected to be made in the 2007 through 2011 time period. Selection of sites for these later capacity additions is not yet needed and has not been made. Please see Table III.B.1).

The four preferred sites are discussed below. FPL has committed to repower existing units at both its Fort Myers and Sanford sites, to add new combustion turbine (CT) capacity at the Fort Myers site, to convert existing CT capacity into combined cycle (CC) capacity at the Martin site, and to add new CC capacity at the Manatee site.

Preferred Site # 1: Fort Myers Plant, Lee County

The site is located on the 460-acre Fort Myers property. Current facilities on the site include two steam electric generating units, nominally 150 MW and 400 MW respectively (which have recently been decommissioned as part of the repowering work), six CT's (that along with heat recovery steam generating (HRSG) units and the existing steam turbines will comprise the repowered facility); and a bank of 12 simple-cycle combustion turbine peaking units. The site has direct access to a four-lane highway, State Road (SR) 80, and barge access is available. The nearest town is Tice, which is approximately 4 miles west of the site. The City of Fort Myers is approximately 8 miles west of the site. The Fort Myers site has been listed as a potential or preferred site in previous FPL Site Plans.

Beyond the current repowering effort, FPL is planning to add two CT's at the site. The CT's are expected to be in service in the Spring of 2003 and will add 318 MW (Summer) and 362 MW (Winter) to FPL's system.

The repowering project currently underway at the site will add approximately 929 MW during Summer conditions and approximately 1,073 MW during Winter conditions. This project is expected to be completed in mid-2002.

The output capability of the existing bank of 12 CT's at the site will be unaffected by the repowering project and the addition of the two new CT's.

a. and b. U.S. geological Survey (USGS) Map and Proposed Facilities Layout Map

A USGS map of the Fort Myers plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter. It is pertinent to note that several designations on the current South Florida Water Management District Florida Land Use, Cover, and Forms Classification System (FLUCCS) appear to be in error, or to require some clarification. For example, the freshwater marsh identified toward the western boundary of the site is actually FPL's 50-acre evaporation/percolation pond. Similarly, while there are scattered mangroves along the shore, the "Central Mangrove" area shown is not mangrove but is the FPL switchyard for that site. The "Improved Pasture" shown towards the east of the site is currently the location of a tree nursery.

d. Existing Land Uses of Site and Adjacent Areas

The land on the site is primarily dedicated to industrial use with surrounding grassy and landscaped areas. There is the previously mentioned 50-acre evaporation/percolation pond on the site. Much of the site is currently being used for either direct construction activities or in support of the repowering project.

FPL has recently donated an 18-acre island, located north of the plant in the Caloosahatchee River, to the United States Fish & Wildlife Service (USFWS) for the purpose of wildlife conservation. This island has been owned by FPL since the 1950's, but has never been developed. The USFWS plans to incorporate the island into the Caloosahatchee National Wildlife Refuge.

Lee County operates Manatee Park (approximately 5 acres) with a manatee viewing area on FPL property to the east side of the discharge canal where it adjoins the Orange River south of SR 80. This manatee viewing area provides public viewing and education about the species. FPL leases the property to the county for a nominal amount.

The adjacent land uses are light commercial and retail to the south of the property and some residential areas located toward the west. Mixed scrub with some hardwoods and wetlands, plus agriculture land, can be found to the east and further to the south. The Caloosahatchee National Wildlife Refuge is located across the Caloosahatchee River, northwest of the power plant.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

The site is adjacent to the south bank of the Caloosahatchee River near the confluence of the Orange River and the Caloosahatchee. Much of the site is no longer in its original natural condition. However, a scattering of mangroves can be found along the river shoreline. Some mixed scrub with some hardwoods and wetlands can be found to the east and further to the south. Other than the occasional congregation of manatees noted below, FPL is not aware of any significant environmental features on the site or in the vicinity.

2. Listed Species

Construction and operation of the repowered facility, plus the new CT's at the site, are not expected to affect any rare, endangered, or threatened species. The only known listed species associated with the site are the West Indian Manatees (Trichechus manatus: Federal - and - State listed as Endangered) which are attracted to the warmed waters in the vicinity of the site discharge and can be found congregating in the area during cool weather.

The Florida Natural Areas Inventory (FNAI) reports the presence of the Eastern Indigo Snake (Drymarchons corais couperi: Federal - and - State listed as Threatened) and Tricolored Heron (Egretta tricolor: State - listed as a Species of Special Concern) within a two-mile radius of the site.

3. Natural Resources of Regional Significance Status

No Natural Resource of Regional Significance is identified on the plant site in the Southwest Florida Regional Strategic Policy Plan.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design options currently being pursued for the Fort Myers site are the repowering of the two existing oil-fired boilers with natural gas-fired CT's and HRSG's, plus the installation of two stand-alone CT's. All of this new generation equipment will be installed on the existing facility property and will make effective use of existing transmission facilities and infrastructure although some transmission line upgrades will be required. Steam developed in the new HRSG's will be directed to the existing steam turbines. FPL has contracted with Florida Gas Transmission (FGT) for a firm natural gas supply to the plant.

Mitigation options being planned for the capacity additions at Fort Myers include: the capture and reuse of plant process water, the use of combustion technology that is inherently low in air pollutant emissions, the reduction of oil barge traffic on the Caloosahatchee River, plumbing the sanitation system to Lee County's system and closing the on-site septic tanks, and closing the on-site ash basins.

g. Local Government Future Land Use Designations

The Local Government Future Land Use Plan designates the major portion of the site as Public Facilities and a small area as Resource Protection. Since there are no significant environmental resources on the site, and the "Resource Protection" designated area appears to be the location of a current tree nursery, FPL believes that this designation is in error.

h. Site Selection Criteria and Process

For the past several years, many of FPL's existing power plant sites have been considered potentially suitable sites for new, expanded, or repowered generation. The Fort Myers plant has been selected as a preferred site due to consideration of various factors including electrical transmission, system load, and economics. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered permittable.

i. Water Resources

The available surface water source is the Caloosahatchee River and the available groundwater source is the shallow aquifer.

j. Geological Features of Site and Adjacent Areas

The geology underlying the Fort Myers Plant consists of Quaternary Holocene and Pleistocene undifferentiated materials. The upper part of these undifferentiated materials consists of fine-to-medium-grained quartz sand with varying percentages of shell and clay. Hardpan frequently occurs at the base of the quartz sands. The lower section consists of shell beds with interbedded limestones. Underlying the undifferentiated materials are the Pliocene Tamiami formations, the Miocene Hawthorn formation, Oligocene Suwanee Limestone, the Eocene Crystal River and Williston formations, the Avon Park Limestone, and the Lake City Limestone.

Several stratigraphic units can be differentiated based upon shallow borings drilled on the plant property. Sand with some heterogeneous fill material related to past site construction activity covers most of the surface. It is underlain by layers of clayey sand and clay to a depth of approximately 23 feet. These units mantle a thicker clay unit with numerous shell fragments that occurs from 15 feet to about 55 feet below the surface. A silty sand with a trace of clay was encountered at 55 feet near the termination depth of one deep boring on the site.

The water table at the site occurs at levels from just under the surface to about 5 feet below grade. Locally, the surficial aquifer and surface water will generally flow toward the Caloosahatchee River. However, at the site, the intake and discharge canal will affect groundwater near the power block area. A drainage canal that borders the plant property on the west will affect groundwater flow along the western portion of the waste treatment area.

k. Projected Water Quantities For Various Uses

It is estimated that 150 gallons per minute (gpm) will be needed for industrial processing water for uses such as boiler makeup and service water. For industrial cooling (once-through cooling water), no significant increase is projected in the current 451,000 gpm usage rate. Other facility water uses may include irrigation, potable use, etc. The total volume of these uses is estimated to be about 5 gpm.

l. Water Supply Sources By Type

For industrial processing, FPL anticipates that groundwater will be available. For cooling water, for the repowered unit, FPL plans to continue to use its existing allocation from the Caloosahatchee River in a once-through cooling mode. The new CT's will be air-cooled.

m. Water Conservation Strategies Under Consideration

A plan to treat and recycle equipment wash water, boiler blowdown, and equipment area runoff for use as service water would reduce ground water consumption. FPL would anticipate this site being designed and classified as a wastewater zero-discharge site following the completion of the repowering work.

n. Water Discharges and Pollution Control

Heated water discharge will be dissipated using both the existing once-through cooling water system and a multi-cell cooling tower. Treating and recycling equipment wash water, boiler blowdown, and equipment area runoff will minimize industrial discharges. Storm water runoff will be collected and used to recharge the surficial aquifer via a stormwater management system. Design elements will be included to capture suspended sediments. Various facility permits mandate various sampling and testing activities, which will provide indication of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

A combustion turbine-based repowering project, plus the addition of the new CT's, requires a natural gas pipeline to be installed. Florida Gas Transmission has initiated permitting to install and operate such a facility. Virtually no waste is associated with natural gas firing.

p. Air Emissions and Control Systems

A natural gas-fired facility would generally have air pollutant emissions, that are substantially lower than emissions from the current oil-fired boilers. While several technologies are available for nitrogen oxide (NO_x) emissions control, FPL is using a dry-low-NO_x combustion turbine design. In these devices, combustion is staged in order to reduce the formation of combustion-derived oxides of nitrogen. FPL has proposed NO_x emission limits for this facility that will be among the lowest in the state once the facility is constructed. Sulfur dioxide and particulate emissions are intrinsically low due to the lack of sulfur and solids in natural gas fuel. Carbon monoxide and volatile organic compound emissions can each be controlled via the use of efficient combustion rather than through the use of add-on control devices. Carbon dioxide emission rates associated with burning natural gas are well below those of other liquid or solid fuels. While the Fort Myers plant site is located within 100 kilometers of a Class I area (Everglades National Park), the reduction in emissions associated with repowering is expected to improve the air quality in the area as compared to current levels. CC and CT facilities have been permitted at several locations throughout the state of Florida including near Class I areas. Dry-low-NO_x combustor systems have been repeatedly demonstrated to be the Best Available Control Technology (BACT) for the control of NO_x emissions for this technology pursuant to the requirements of the Clean Air Act.

q. Noise Emissions and Control systems

Lee County has a noise ordinance which limits noise at the receiving property line to 75 decibels. Noise emissions from the Fort Myers project are not anticipated to approach this level based upon demonstrated noise control at similar natural gas-fired facilities (the Lauderdale plant in Broward County and the Martin plant in Martin County) and computer modeling of the anticipated noise emissions from the Fort Myers repowered plant. FPL will undertake studies to assure that noise level associated with the new CT's comply with Lee County noise standard.

r. Status of Applications

FPL has received all the permits necessary to construct and start up the repowered plant and the two new CT units.

Preferred Site # 2: Sanford Plant, Volusia County

The site is located on the 1,718–acre FPL Sanford property just west of Lake Monroe on the north bank of St. Johns River in Volusia County. Current facilities on the site include three steam electric generating units (one with a nominal rating of 150 MW and two with nominal ratings of 400 MW). The site is within the city limits of Debary and the community of Debary is located approximately 2 miles to the northwest. The town of Deland is approximately 4 miles west of the site. The site has direct access to a four-lane highway, State Road (SR) 17-92, and barge access is available. The Sanford site has been listed as a potential or preferred site in previous FPL Site Plans.

FPL is currently in the process of adding new capacity at the Sanford site by replacing two existing oil-and gas-fired units (i.e., existing units # 4 and # 5) with advanced natural gas-fired combustion turbines (CT's) and heat recovery steam generators (HRSG's). This type of steam generation replacement is commonly called "repowering".

This repowering will enable FPL to produce significantly more electrical output with nearly the same environmental impact. The repowering of units # 4 and # 5 will each produce approximately 567 additional MW during Summer conditions, and approximately 671 additional MW of generation during Winter conditions, beyond the current capabilities of these units. The two repowered units # 5 and # 4 were projected to be in-service by mid-2002 and late-2002, respectively. The existing 150 MW unit # 3 at Sanford will be unaffected by the repowering of units # 5 and # 4.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout Map

A USGS map of the Sanford plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A large part of the property is covered by the 1,100-acre closed-cycle-cooling pond which occupies almost all of the northern portion of the site. The remainder of the site is primarily rangeland and the power plant facilities.

The surrounding land use is largely crop land and pasture. To the east of the plant there is a small residential area and some commercial/industrial land use. There are some residential areas mixed in with the agricultural areas located between the site and the St. John's River to the west. To the south is the St. Johns River and residential homes and commercial/industrial businesses are located along the south side of the river.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

Small, scattered wooded areas can be found on the site. There are two small areas of wetland marsh on the site and a few acres of wetland forest along the riverbank. There are some wooded areas on the site, primarily upland coniferous forest. Forested and non-forested wetlands can be found to the west, adjacent to the river. Rover and wetland areas towards the northwest are designated as part of the Wekiwa River Aquatic Preserve and Wekiwa River State Preserve.

2. Listed Species

One inactive bald eagle (Haliaeetus leucocephalus: Federal - and - State listed as Threatened) nest has been found on the site. Bald eagles have also nested in the Lake Monroe area. There are a number of other eagle nests in the vicinity of the site, primarily along the St. Johns river. The Florida Natural Areas Inventory (FNAI) reports several Scrub Jay populations (Aphelocoma coerulescens: Federal - and - State listed as Threatened) located in scrub vegetation to the northwest of the site. West Indian Manatees (Trichechus manatus: Federal - and - State listed as Endangered) have also been found in this area.

3. Natural Resources of Regional Significance Status

The Wekiwa River Aquatic Preserve extends along the St. John's River in the vicinity of the plant.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option for the Sanford site is the repowering of two existing oil-and gas-fired boilers with natural gas-fired combustion turbines (CT's) and heat recovery steam generators (HRSG's). Advanced CT's can be installed on the existing facility property to make effective use of existing transmission facilities and infrastructure although some transmission line upgrades will be required. Steam produced in the new HRSG's will be directed to two of the existing steam turbines. Natural gas-fired facilities represent one of the cleanest, most efficient technologies currently available for capacity additions to FPL's system.

Mitigation options being considered in the repowering project at Sanford include the reduction in the use of ground water, the use of combustion technology that is inherently low in air pollutant emissions, reduction in the amount of solid waste generated, plumbing the sanitary waste system into the Volusia county system, and the significant reduction of oil barge traffic on the St. Johns River.

g. Local Governmental Future Land Use Designations

The site is designated as "Industrial Utilities" in the Local Government land use plan. The city is currently updating its Land Use Plan. It is expected that the name, but not the expected use designation, may change. Land use designation of the surrounding area is primarily Agricultural. There is an area of "Public Institution" around Lake Monroe to the southeast and a small area of "Mixed Use" to the west along Barwick Road.

h. Site Selection Criteria and Process

The Sanford plant has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All are considered permittable.

i. Water Resources

For surface water supply, the available water resource is the St. John's River and / or the on-site cooling pond, which is periodically refilled from the St. John's River. For groundwater supply, the available resources are the shallow aquifer or the Floridan Aquifer.

j. Geological Features of Site and Adjacent Areas

The near-surface geology of Volusia County, like that of most of north central Florida, is represented by late Tertiary and Quaternary geologic units. Soils in the vicinity of the plant include unconsolidated Pleistocene to Recent sands, with intervening beds of shells and clay. These deposits form the reservoir for the surficial aquifer in the county. Deposits of Pliocene or Miocene clay with some sand underlie the aquifer. These low-permeability units serve to confine groundwater under pressure in the underlying porous limestone formations of Eocene age. These formations are part of the principal hydrologic unit referred to as the Floridian Aquifer. This aquifer, the top of which generally occurs through the region at or below 100 feet, is the major source of potable groundwater in Volusia County. Two faults, one trending north-to-south, the other trending east-to west, intersect a number of miles north of the site. Downward displacement of the fault is hypothesized as being approximately 60 to 100 feet.

k. Projected Water Quantities for Various Uses

FPL has estimated that 150 gallons per minute (gpm) would be required for industrial processing purposes (boiler makeup, service water, etc.). Note that Units # 5 and # 4 both currently take their cooling water directly from an on-site FPL cooling pond and are expected to continue to do so once the units are repowered. The cooling water needs for the repowered facilities are expected to increase over what is currently used, due primarily to the increased heat loading to the cooling pond that will result from operating the larger repowered units more than they have been operated in the past, and corresponding evaporative losses. Therefore, greater quantities of water may be used. Existing Unit # 3 will use water from the St. John's River in a once-through cooling mode.

FPL also evaluated alternative sources of water to meet the expected needs of the site. It is anticipated that the existing off-site wells and the existing once-through cooling water system and cooling pond would continue to be used after the repowering project is completed, albeit the use of groundwater is expected to decrease significantly from past usage.

l. Water Supply Sources by Type

The available surface water supply source is the St. Johns River. The Floridan Aquifer is an available groundwater source for service water and boiler water.

m. Water Conservation Strategies Under Consideration

In 2000 FPL obtained a revised Consumptive Use permit from the St. Johns Water Management District. This permit reduced the quantity of water that FPL has historically been permitted to withdraw from the ground, in favor of additional use of surface water (preferred).

n. Water Discharges and Pollution Control

Heated water discharge will be dissipated using the existing once-through cooling water system. Non-point source discharges are not anticipated to be an issue because surface water runoff is planned to be collected and reused. Treating and recycling equipment wash water, boiler blowdown, and equipment area runoff will minimize industrial discharges. Storm water runoff will be collected and used to recharge the surficial aquifer via a stormwater management system. Design elements will be included to capture suspended sediments. Various facility permits mandate various sampling and testing activities, which will provide indication of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The repowered facilities at the Sanford site would require a larger natural gas pipeline to be installed. FPL has contracted with Florida Gas Transmission Company (FGT) to permit, install, and operate such a facility. Virtually no waste is associated with natural gas firing.

p. Air Emissions and Control Systems

A natural gas-fired facility would generally have air pollutant emissions which are substantially lower than emissions from the current oil-fired boilers. While several technologies are available for nitrogen oxide (NO_x) emissions control, the most appropriate candidate for the Sanford site is a dry-low-NO_x combustion turbine design type. In these types of devices, combustion is staged in order to reduce the formation of combustion-derived oxides of nitrogen. Sulfur dioxide and particulate emissions are intrinsically low, due to the lack of sulfur and solids in natural gas fuel. Carbon monoxide and volatile organic compound emissions can each be controlled via the use of efficient combustion, rather than through the use of add-on control devices. CC and CT facilities have been permitted at several locations throughout the state of Florida. Dry-low-NO_x combustor systems have been repeatedly demonstrated to be the Best Available Control Technology (BACT) for the control of NO_x emissions for this technology pursuant to the requirements of the Clean Air Act.

q. Noise Emissions and Control Systems

Noise emissions from the project are not anticipated to be significantly different from current levels at the existing plant. FPL will install appropriate sound attenuation devices such as insulation on high-energy piping systems in order to ensure that sound levels do not exceed allowable levels. Similar natural gas-fired facilities (the Lauderdale plant in Broward County and the Martin plant in Martin County) have been constructed and operated without exceeding allowable noise levels.

r. Status of Applications

FPL has now acquired all permits needed to commence construction. Modifications to operating permits will continue to be pursued as necessary through 2002.

Preferred Site # 3: Manatee Plant, Manatee County

The site is located in unincorporated north-central Manatee County approximately 2.5 miles south of The Hillsborough-Manatee County line. It is 5 miles east of Parrish, Florida and is approximately 5 miles east of U.S. Hwy. 301 and 9.5 miles east of Interstate 75 (I-75). State Road 62 (S.R.62) is about 0.5 miles south of the site. Safford Road marks the eastern boundary of the site.

FPL's Manatee Plant occupies a portion of the approximately 9,500 acre Manatee Site, which is owned wholly by FPL. The site includes a 4,000 acre cooling pond including the dike area. The existing approx.1,625 MW (net summer) of generating capacity is made up of two steam units (Units # 1 and # 2) which have been in service since 1976 (Unit # 1) and 1977 (Unit # 2). These units currently burn fuel oil (residual) with a maximum sulfur content of 1 percent. A recent agreement between FPL and Gulfstream Natural Gas Systems will provide an alternative fuel source (natural gas) for these units.

Additional generating capacity will be added to the site to meet projected energy needs for 2005 and 2006. Four new combustion turbines (CT's), four new heat recovery steam generators (HRSG's), and a new steam turbine generator are scheduled for in-service operation beginning in June, 2005. The four new CT's, HRSGs and steam turbine will ultimately be operating in combined cycle (CC) configuration. This new CC unit will add 1,107 MW (Net Summer) and 1,197 MW (Net Winter) capability to the site. This new CC Unit will be designated as "Manatee Unit # 3".

Unit # 3 will be located west of the existing generating Units # 1 and # 2. The location of the new combined cycle Unit # 3 at the Manatee Plant site and the selection of the highly efficient combined cycle technology (firing clean natural gas) will maximize the beneficial use of the site while minimizing environmental, and land use impacts otherwise associated with the development of a new generating plant of this capacity.

a.and b. Map of the Manatee Plant Site and Land use

A map indicating the Manatee plant site showing the general layout of the facilities and a map indicating the land use of the site are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 4,000 acre cooling pond. Manatee Units # 1 and # 2 will not be affected by the addition of Unit # 3. The area for Unit # 3 is expected to comprise approximately 73 acres. The site and surrounding land uses are almost exclusively agricultural with the exception of the Willow Shores residential area located northwest of the Manatee Plant site. Individual homes are located in the larger of two outparcels within the Manatee Plant site, along SR 62 at the northeast corner of the site. The vast majority of the Manatee Plant site is located in the Agricultural/Rural land use category. Other portions of the site are designated as Major Public/Semi Public (1) (P/SP). Electric generating plants are specifically allowed in the Agricultural/R and P/SP category in accordance with the Manatee County Local

Government Comprehensive Plan and Land Development Regulation Act, Chapter 163, Part II, Florida Statues (FS).

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

There are no incorporated areas within 5 miles of the Manatee Plant site. Unincorporated communities in the area include Willow, located about 2 miles north of the Manatee Plant; Parrish, located about 5 miles southwest of the plant; and in Hillsborough County, Sundance, located 3 miles northwest of the plant, Sun City Center, located 7 miles north of the plant; and Wimauma, located 8 miles northeast of the plant.

The Manatee Plant site includes areas of improved pasture with forested land southeast of the Project area. This forested area is comprised of flatwoods and oak habitat. The western side of the Manatee Plant site is currently used for row crops (tomato farm). There are also wetlands to the southeast of the Project area containing wet pine flatwoods mixed with dry pine flatwoods. There will not be any disturbance of existing wetlands associated with this project.

2. Listed Species

Construction and operation of the new Unit # 3 at the site is not expected to affect any rare, endangered, or threatened species. The majority of the site is cleared, grassed and periodically mowed. The project area has been significantly altered by the construction and operation of the existing plant facilities, as a result wildlife utilization of this area is expected to be minimal. Common wading birds utilizing the plant site outside of the project area, include the great blue heron, little blue heron, great egret, snowy egret and the white ibis. Typical mammals found in the habitats surrounding the project area are common bobcat, raccoon, deer, feral hog, opossum, armadillo, skunk and gray squirrel. Avian species observed in the vicinity of the project include a variety of songbirds, red-shouldered hawk and marsh hawk.

3. Natural Resources of Regional Significance Status

There are no County, State or Federally designated areas located within 1 mile of the plant site. The construction and operation of Manatee Unit # 3 is not expected to have any adverse impacts on parks, recreation areas or environmentally sensitive lands that are associated with the Little Manatee River within a 5 mile radius of the project site. These lands include: Little Manatee River State Recreation Area, Little Manatee River State Canoe Trail, Florida Gulf Coast Railroad Museum, Cockroach Bay Aquatic Preserve, Critical Manatee Habitat, South Hillsborough Wildlife Corridor, Hillsborough County ELAPP Parcels and SOR-Little Manatee River.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design for Manatee Unit # 3 is the addition of four new CT's, with four new HRSGs and one new steam turbine generator in combined cycle configuration (creating a 4X1 configuration). Manatee Unit # 3 will begin operation in mid – 2005. Natural gas, delivered via pipeline, will be the sole fuel for this unit. Natural gas fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation options being planned for Manatee Unit # 3 include the capture and reuse of plant process water and rainwater. In addition, other mitigating options include the use of combustion technology that is very efficient and low in air pollutant emissions, combined with pollution control technology (dry-low NO_x burners and selected catalytic reduction equipment).

g. Local government Future Land Use Designations

As mentioned above the Local Government Future Land Use Plan is consistent with the existing Designated uses of the Manatee Plant Site as major portions of the site are Agriculture/R and the remainder is designated as Major Public/Semi Public (1) – P/PS. Electric generating plants are specifically allowed in these land use categories .

h. Site Selection Criteria and Process

For the past several years, many of FPL's existing power plant sites have been considered potentially suitable sites for new, expanded, or repowered generation. The Manatee site has been selected as a preferred site due to consideration of various factors including system load and economics. The projected availability of a natural gas pipeline that will be available to Unit # 3 as well as Units # 1 and # 2 in the near future was also a major factor in the selection of the Manatee site for the new 4x1 CC unit. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All of these site are considered permittable.

i. Water Resources

The available surface water source is the Little Manatee River. Make up water for the 4,000 acre cooling pond will continue to be provided from the Little Manatee River. Plant process and service water requirements are currently supplied by the cooling pond, there are three wells in the Floridan aquifer that are reserved for standby purposes.

j. Geological Features of Site and Adjacent Areas

The Geology underlying the Manatee Plant consist of unconsolidated sediments comprised of sand, clay silt, marl shell, limestone and phosphorite (terrace deposits) from the Pleistocene age to Recent. Undifferentiated Deposits comprised of sand and clay with Pliocene age and includes the Bone Valley Formation which is generally described to be less than 25 feet thick. Underlying the undifferentiated materials are the Miocene Hawthorn Formation, the Tampa Member, the Suwannee Limestone of the Oligocene age, the Ocala Limestone of the Eocene Age, the Avon Park Formation, the Oldsmar Formation of the Eocene age and the Cedar Key Formation of the Paleocene age.

k. Projected Water Quantities For Various Uses

The estimated additional quantity of water for industrial processing is estimated to be 150 gpm (gallons per minute) plant process and service water. FPL operates on-site water treatment systems for each of these uses. Water quantities for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l. Water Supply Sources by Type

Manatee Unit # 3 will utilize the existing on-site cooling pond as its source of cooling water. The cooling pond operates as a "closed cycle" system, any makeup water is provided from the Little Manatee River to replace net evaporation and seepage loses from the pond. These makeup needs are within the existing agreement between FPL and the Southwest Florida Water Management District (SWFWMD). There are three wells, currently on Reserve (standby) that are in the Floridan Aquifer.

FPL is currently evaluating alternative water sources for use at the Manatee Plant site.

m. Water Conservation Strategies Under Consideration

Available water including non-contact storm water, treated industrial wastewater, treated sanitary wastewater, and recovered service water are captured and returned to the cooling pond. Storm water from the equipment areas is also treated and returned to the cooling pond.

n. Water Discharges and Pollution Control

The Manatee Plant employs a Best Management Practices (BMP) plan, a Spill Prevention, Control and Countermeasure (SPCC) plan to assist in the control of inadvertent release of pollutants. Stormwater runoff will be collected and routed to detention ponds. Construction activities will be managed so that equipment maintenance and fueling are designated areas to conduct these activities so that in the event of a spill or release of any contaminant, impacts to any surface water or the cooling pond are minimized.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by fuel delivery services and facilities for residual, low sulfur (1 percent) fuel oil. FPL has an agreement with Gulfstream Natural Gas Systems to install a natural gas lateral to the Manatee Plant that will provide the availability of natural gas for existing Units # 1 and # 2. The addition of Unit # 3, that will be solely fueled by natural gas, will require further negotiations or agreements with Gulfstream or some other supplier.

p. Air Emissions and Control Systems

The use of clean fuels and combustion controls will minimize air emissions from Unit # 3 and ensure compliance with applicable emission limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of Manatee Unit # 3 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise emissions from the project are not anticipated to be significantly different from the current levels at the existing plant. Similar natural gas-fired facilities in Broward and Martin Counties have been constructed and operated without exceeding allowable noise levels.

r. Status of Applications

FPL filed the Site Certification Application (SCA) for the Manatee Plant Unit # 3 with the Florida Department of Environmental Protection (FDEP) on February 20, 2002.

Preferred Site # 4: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District (SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad.

The Martin site was identified in 1987 as a preferred location for development of coal gasification/combined cycle electric generation facilities and subsequent FPL Site Plans have continued to identify this site as a preferred site.

The existing 2,906 MW (net Summer) of generating capacity at FPL's Martin site occupies a portion of the approximately 11,300 acres that are wholly owned by FPL. The generating capacity is made up of two steam units (Units # 1 and # 2), plus two combined cycle units (Units # 3 and # 4), and two combustion turbine units (Units # 8a and # 8b). The site includes a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

Additional generating capacity will be added to the site. The existing two CT's at the site will be converted into a four on one (4X1) combined cycle (CC) unit with the addition of two new CTs and four new HRSGs and a new steam turbine generator in mid - 2005. The two existing CT's total capabilities are 318 MW (Summer) and 362 MW (Winter). The later conversion of these two CT's to a (4X1) CC will add approximately 789 MW (Summer) and 835 MW (Winter) of capacity. The new CC unit will be designated as Unit # 8.

a) and b) U.S. Geological Survey (USGS) Map and Proposed Facilities Layout Map

A USGS map of the Martin plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c) Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d) Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres. To the east of the power plant there is an area of mixed pine flatwood with a scattering of small wetlands. To the north of the reservoir there is a 1,200-acre area which has been set aside as a mitigation area. There is peninsula of wetland forest on the west side of the reservoir which is named the Barley Barber Swamp. The Barley Barber Swamp encompasses

400 acres and is preserved as a natural area. There is also a 10 kilowatt (KW) photovoltaic energy facility at the south end of this site.

e) General Environment Features On and In The Site Vicinity

1) Natural Environment

As noted above, the Barley Barber Swamp is located on the site. There is also a 1,200-acre mitigation area in the northern area of the site where wetlands and uplands have been restored. Along the south and west sides of the cooling pond is an area where the vegetation has been allowed to return to its natural state in order to serve as a wildlife corridor. FPL has preserved a Florida Panther corridor along the west side of the cooling pond. There are pine flatwoods and small scattered wetlands to the east of the plant.

2) Listed Species

Construction and operation of new units at the site are not expected to affect any rare, endangered, or threatened species. There are two active Bald Eagle (Haliaeetus leucocephalus: Federal - and - State listed as Threatened) nests that have been on the site for many years. The Florida Natural Areas Inventory (FNAI) database notes a record of Eastern Indigo Snakes (Drymachon coralis coupert which are Federal - and - State listed as Threatened) in the Barley Barber Swamp. A number of other Bald Eagle nests and sightings of Eastern Indigo Snakes are reported by the FNAI database within a two-mile radius of the site. Infrequent sightings of Florida Panther have been made in the site area.

3) Natural Resources of Regional Significance Status

The Treasure Coast Regional Planning Council lists the "FPL Preserve", including the Barley Barber Swamp, as a Significant Regional Facility. Natural communities such as uplands and wetlands are also generically listed as Resources of Regional Significance.

4) Other significant features

FPL is not aware of any other significant features of the site.

f) Design Features and Mitigation Options

The design options are to add two new CT's and four new HRSG's and a new steam turbine that, together with the two existing CT's, will comprise Martin Unit # 8. This unit is scheduled to be in service in mid-2005. Natural gas delivered via pipeline is envisioned as the fuel type for this unit (with light oil serving as a backup fuel). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation options being considered include the capture and reuse of plant process water and rainwater. The facility already encompasses several preserved areas where wildlife is abundant.

g) Local Government Future Land Use Designations

Local government future land use designation for the site is "Public Utilities". Designations for the surrounding area are primarily "Agricultural". There are also limited areas of "Agricultural Ranchette", "Industrial", and a small "Commercial" area designation. To the southeast of the property, fronting on the St. Lucie Canal, there is an area designated for "Public Conservation".

h) Site Selection Criteria and Process

For the past several years, a number of FPL's existing power plant sites have been considered as potentially suitable sites for new or repowered generation. The Martin plant has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor in FPL's site evaluation since none of the existing preferred and potential site exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered permittable.

i) Water Resources

Surface water resources currently used at the Martin facility include the cooling pond, which takes its water from the St. Lucie canal. The available groundwater resource is the shallow aquifer which is used as a source of potable water and for service water for Units # 1 and # 2. Both of these sources are available for use with the site expansion.

j) Geological Features of Site and Adjacent Areas

FPL's Martin site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine in origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The deepest formation in Martin County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Lake City formation. The published information on the sediments comprising the formations below the Avon Park Limestone in western Martin County is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach counties.

k) Projected Water Quantities for Various Uses

The estimated additional quantity of water required for industrial processing is 130 gallons per minute (gpm) for uses such as boiler water and service water. FPL operates on-site water treatment systems for each of these uses. Cooling water for new Unit # 8, will be supplied from the on-site 6,800-acre cooling pond. Makeup water for the pond is taken from the St. Lucie canal. The current makeup water quantity to the cooling pond (approximately 4,800 gpm) is expected to be adequate for the proposed expansion. Water quantities needed for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l) Water Supply Sources by Type

All additional capacity at the site will utilize the existing on-site cooling pond as the source of cooling water and as a heat sink for the dissipation of cooling water heat. The cooling pond operates as a "closed cycle" system in which heated water from the generating units loses its heat as it is circulated within the pond and back around to the plant intake. A cooling tower may also be utilized. Makeup water to the pond is withdrawn from the St. Lucie Canal as needed to replace net evaporation and seepage losses from the pond. Such needs will comply with the existing agreement between FPL and the South Florida Water Management District (SFWMD) regarding allocation of cooling water to the pond and with SFWMD's regulations for consumptive water use.

The existing water treatment system at the plant, which provides treated water for use in the Unit # 1 and # 2 boilers, as well as the HRSG's associated with Units # 3 and # 4, will be expanded to provide treated water for new Unit # 8. FPL will discuss Unit # 8 requirements with SFWMD as the project moves forward in the licensing process.

m) Water Conservation Strategies Under Consideration

Impacts on the surficial aquifer will be reduced by changing the source of plant process water to the Floridan aquifer, upon completion of Unit # 8. In addition, the facility captures and reuses process water whenever feasible, and manages stormwater in such a manner so as to recharge the surficial aquifer.

n) Water Discharges and Pollution Control

Heated water discharges will be dissipated in the cooling pond. Non-point source discharges are not an issue since there are none at this facility. Industrial discharges will be minimized by treating and recycling equipment wash water, boiler blowdown water, and equipment area runoff. Storm water runoff is collected and used to recharge the surficial aquifer via a stormwater management system. Design elements have been included to capture suspended sediments. Facility permits mandate various sampling and testing activities, which provide indication of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o) Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by multiple fuel delivery facilities. There are currently two pipelines with the capability of supplying of natural gas into the facility. The additional capacity due to the conversion of the CT's into a CC unit will require an enlargement of an existing pipeline(s), the installation of a new pipeline, or the addition of another natural gas pipeline compressor station.

p) Air Emissions and Control Systems

The use of clean fuels and combustion controls will minimize air emissions from Unit # 8 and ensure compliance with applicable emission limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO2), particulate matter and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during CC operation when firing light oil. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of Martin Unit # 8 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q) Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise will be below current noise levels for the residents nearest the site. Noise from the operation of the new units will also be within allowable levels.

r) Status of Applications

A Site Certification application was filed in December, 1989, for the construction and operation of the Martin Coal Gasification/Combined Cycle project under the Florida Electrical Power Plant Siting Act.

On June 15, 1990, the Public Service Commission issued a Determination of Need Order for proposed Martin Units # 3 and # 4. This determination of need applies only to the first phase of the Project, or 832 MW of combined cycle generation. The Siting Board issued a Land Use Order on June 27, 1990. The Certification Hearing was held on November 5-7, 1990. As mentioned earlier, on February 12, 1991, the Governor and Cabinet, serving as the Siting Board, approved the construction and operation of natural gas-fired combined cycle Units # 3 and # 4 and determined that the Martin Site has capacity to accommodate additional combined cycle units fueled by natural gas, fuel oil, or coal-derived gas produced at the site.

Since the initial certification in 1991, the Site Certification has been modified five times to provide authorization for items such as CT testing, increasing the cooling pond elevation, incorporating changes from other permits, and incorporating a custom fuel monitoring program. For the addition of the two CT's, FPL obtained a sixth modification to the existing Site Certification in August 2000.

In order to convert these two CT's from simple cycle to CC configuration, a seventh modification to the Site Certification will be required. FPL filed the Site Certification Application on February 1, 2002 with the FDEP.

IV.F.2. Potential Sites

Four FPL-owned sites are identified as the next most likely potential sites for future generation after the four preferred sites just discussed. These four sites are considered the next most likely potential sites due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are located in Brevard, Palm Beach, Broward, and St. Lucie Counties. These sites are suitable for different capacity levels and technologies, and they will remain as potential sites pending future decisions on how best to meet the timing and magnitude of FPL's future capacity needs.[2]

Each of these potential sites offers advantages and disadvantages relative to engineering considerations and/or costs associated with the construction and operation of feasible technologies. In addition, each potential site has different characteristics, which could require further definition and attention. For purposes of estimating water usage amounts, it

[2] As has been described in previous FPL Plant Site Plans, FPL also considers a number of other sites as possible sites for future generation additions These include the remainder of FPL's existing generation sites.

is assumed that a natural gas-fired CC unit would be the technology of choice for any capacity additions at the sites.

Permits are presently considered to be obtainable for all four sites, assuming measures can be taken to mitigate any particular site-specific environmental concerns. None of the sites exhibit any significant environmental constraints. The potential sites are briefly discussed below. (Note: The order in which the sites are discussed below does not reflect a relative ranking of these sites in regard to how likely it is for FPL to add capacity at the site.)

Potential Site # 1: Cape Canaveral Plant, Brevard County

The site is located on the FPL Cape Canaveral property in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The existing facility consists of two 400 MW (nominal) steam boiler type generating units.

a) U.S. Geological Survey (USGS) Map

A USGS map of the Cape Canaveral plant site is found at the end of this chapter.

b) and c) Land Uses and Environmental Features

This site is located on the Indian River. The land is primarily dedicated to industrial use with surrounding grassy areas and a few acres of remnant pine forest. The land adjacent to the site is dedicated to light commercial and residential use. There are no significant environmental features on the site.

d) and e) Water Quantities and Supply Sources

FPL projects that an increase of up to 260 gallons per minute (gpm) would be required for industrial processing use (boiler makeup, service water, etc.) It is expected that industrial cooling water needs could be met using the current 550,000 gpm once-through cooling water quantity. For industrial processing, FPL would use existing on-site wells. For industrial cooling, the Indian River would continue to be utilized.

Potential Site # 2: Riviera Plant, Palm Beach County

This site is located on the FPL Riviera Plant property in Riviera Beach, Palm Beach County. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (nominal) steam boiler generating units and one retired 50 MW generating unit.

a) U.S. Geological Survey (USGS) Map

A USGS map of the Riviera plant site is found at the end of this chapter.

b) and c) Land Uses and Environmental Features

The land on the site is primarily covered by the existing generation facilities with some open maintained grass areas. There is a small manatee viewing area on the site which is operated seasonally by FPL. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development. The site is located on the Intracoastal Waterway near the Lake Worth Inlet.

d) and e) Water Quantities and Supply Sources

Additional industrial processing water needs are estimated to be up to 40 gallons per minute (gpm). Industrial cooling water needs are estimated to be up to 54,000 gpm using the existing once-through cooling water system. The existing municipal water supply would be used for industrial processing water if additional generating capacity is placed at Riviera. For once-through cooling water, FPL would continue to use Lake Worth as a source of water.

Potential Site # 3: Port Everglades Plant, Broward County

This site is located on the 94-acre FPL Port Everglades plant site in Port Everglades, Broward County. The site has convenient access to State Road (SR) 84 and Interstate 595. A rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (nominal) and two 400 MW (nominal) sized units.

a) U.S. Geological Survey (USGS) Map

A USGS map of the Port Everglades plant site is found at the end of this chapter.

b) and c) Land Uses and Environmental Features

The land on the site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

d) and e) Water Quantities and Supply Sources

FPL estimates that up to 130 gallons per minute (gpm) of industrial processing water would be required for uses such as boiler makeup, fogger usage, and service water. FPL would expect to use the existing municipal water supply for industrial process water. For cooling water, FPL would anticipate that the existing 320,000 gpm once-through cooling seawater source would continue to be used.

Potential Site # 4: Midway Substation Property, St. Lucie County

The site is located on the 122-acre Midway Substation property. Current facilities on the site include an electric substation. The site has direct access to a two-lane highway, State Road 712 (SR 712). The nearest town is White City, which is approximately 5 miles east of the site. The City of Fort Pierce is approximately 9 miles northeast of the site. The Midway site was previously listed as a preferred site in the FPL 2001-2010 Ten Year Power Plant Site Plan.

a) U.S. Geological Survey (USGS) Map

A map is provided of the Midway Site area and a land use map is provided at the end of this chapter.

b) and c) Land Uses and Environmental Features

The land on the site is currently dedicated to industrial and agricultural use. Much of the site is currently not being used. Developed portions of the adjacent properties are primarily agricultural (orange groves and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and wetlands.

d) and e) Water Quantities and Supply Sources

No surface water source is available at this site. The groundwater source would either be the shallow aquifer or a local source of gray water. It is estimated that 150 gallons per minute (gpm) will be needed for industrial processing water for uses such as inlet air-cooling, NO_x control during light oil firing and for service water. Other facility water uses may include irrigation, potable use, etc. The total volume of these uses is estimated to be about 5 gpm.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission constraints. External constraints deal with FPL's ties to its neighboring systems. Internal constraints deal with the flow of electricity within the FPL system. The projected effects of these constraints are modeled in FPL's resource planning work.

The external constraints are important since they affect the development of assumptions for the amount of external assistance which is available and the amount and price of economy energy purchases. Therefore, these external constraints are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission constraints or limitations are addressed in developing the costs for siting new units at different locations. Site-specific transmission costs are developed for each different unit/unit location option or groups of options.

FPL's annual transmission planning work determines transmission additions needed to address constraints and to maintain/enhance system reliability. FPL's transmission plans are presented in Section III.E.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

As discussed in Chapter III of this document, FPL typically performs economic analyses of competing resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI) and Stone and Webster Management Consultants, Inc. The resource plan reflected in this document emerged as the resource plan with the least impact on FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach) and on the present value of revenue requirements for the FPL system.[3]

As part of its 2001 resource planning work, FPL issued a Request for Proposals (RFP) for firm capacity offerings designed to address FPL 2005 and 2006 capacity needs. FPL received 81 proposals in response to the RFP. These outside proposals, and 13 FPL construction options, were subsequently evaluated by FPL using the EGEAS model. Following the EGEAS calculations, three other calculations designed to determine generator startup costs, transmission integration costs, and equity penalty costs were made. These other costs were then added to the EGEAS costs to develop total costs (in terms of the cumulative present value of revenue requirements) for the competing options. A similar analysis of the outside proposals and FPL construction options was performed independently by an outside consultant.

No sensitivity case analyses based on different load forecasts were carried out during 2001. This is due to the fact that the vast majority of the options studied, including the two most economical options (the Martin Conversion project and the new Manatee unit), are combined cycle (CC) units. If higher – than – projected loads begin to appear, the combustion turbine components of any of the CC options could be placed in service early in simple cycle mode. FPL believed that this fact qualitatively enabled it to be able to address higher – than – projected loads. A quantitative analysis of this occurrence was not possible since the proposals did not include costs for such a scenario.

[3] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases (as in FPL's 2001 resource planning work), FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its base case or "Most Likely" fuel price forecast are discussed in Chapter III of this document.

In its 2001 planning work, FPL did not test the sensitivity of its resource plan to a "Low Price" fuel forecast in conjunction with a "High Load" forecast. The reason given in response to Discussion Item # 2 explains why FPL felt that a high load forecast scenario was not needed. Similarly, since the vast majority of the options considered in the RFP analysis were gas-fired units, any change in the fuel costs projections would have affected these proposals in essentially the same way. Consequently, FPL did not believe that a fuel price sensitivity case was needed.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

For the same reason given in response to Discussion Item #3, FPL did not conduct a "constant fuel differential" sensitivity analysis in its 2001 planning work.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, and capacity output ratings and heat rate information. Schedule 1 and Schedule 8 present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add over the planing horizon is presented on Schedule 9.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

The key financial assumptions used in FPL's 2001 resource planning work were 45% debt and 55% equity FPL capital structure, projected debt cost of 7.4%, and an equity return of 11.7%. These assumptions resulted in a weighted average cost of capital of 9.8% and an after-tax discount rate of 8.5%. In its 2001 planning work, FPL did not test the sensitivity of its resource plan to varying financial assumptions. The reason for this is that in recent years FPL's planning work has focused on FPL construction options only. Results between higher capital cost options and lower capital cost options could have changed as financial (primarily capital cost) assumptions changed.

However, in its 2001 planning work, outside proposals were analyzed versus the FPL construction options. While FPL could have examined the effect of different financial assumptions on its options, there simply is no practical way to request, receive and reanalyze new cost information for the outside proposals based on a common set of new financial assumptions (such as higher debt rates). The complexity and length of time inherent in an RFP-based process precludes this analysis.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). However, in its 2001 planning work FPL utilized a net present value of system revenue requirements as the basis for comparing options and plans. (As discussed in response to Discussion Item # 2, both the electricity rate basis and the system revenue requirement basis are identical when DSM levels are unchanged between competing plans. Such was the case in FPL's 2001 planning work.)

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two generation reliability criteria in its resource planning work. One of these is a minimum 15% Summer and Winter reserve margin for years up to mid – 2004 that changes to a minimum 20% Summer and Winter reserve margin for the mid – 2004 – on time period. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the planning criteria established by the North American Electric Reliability Council (NERC) in its *Planning Standards.* FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Planning Standards* are available on the internet (http://www.nerc.com/~filez/pss-psg.html).

In addition, FPL has developed a Facility Connection Requirements (FCR) document as well as a Facility Rating Methodology document that are also available on the internet (http://www.enx.com/FPL/fpl_home.html).

Thermal ratings for specific transmission lines or transformers are found in the load flow cases that are available on the internet (http://www.enx.com/FPL/fpl_home.html). The normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138, 500	0.95	1.05
230	0.95	1.06

There may have been isolated cases for which FPL may have determined it prudent to deviate from the general criteria stated above. The overall potential impact on customers, the probability of an outage actually occurring, as well as other factors may have influenced the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption are revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all the FPL programs in order to adjust impacts each year for changes in the mix of efficiency measure being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. Finally, FPL is careful to only claim program savings for the average life of the installed efficiency measure. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

The strategic or non-price factors FPL considers when choosing between resource options include: (1) fuel diversity; (2) technology risk; and (3) environmental risk.

Fuel diversity relates to two concepts, the diversity of sources of fuel (e.g., coal vs. oil vs. natural gas), and the diversity of supply for a single fuel source (for example alternative pipeline suppliers for natural gas). All other factors being equal, supply options that increase fuel supply diversity would be favored over those that do not.

Technology risk is an assessment of the relative maturity competing technologies, For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use, and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of competing technologies. Technologies which might be regarded as more acceptable from an environmental perspective (e.g., natural gas) might be considered more favorably.

When choosing between an FPL self-build option and buying power, the strategic or non-price factors FPL considers also include: (1) the financial strength of the supplier; (2) the feasibility of licensing and construction requirements; (3) the delivery risk related to firmness of fuel supply and the experience of the seller; and (4) the degree of control offered, including dispatchability and rights to sell power.

The financial strength of the supplier is an assessment of the ability of a project developer to marshal the financial resources required to bring a capital-intensive project to completion. While it has always been a concern, this issue has become even more prominent in light of the collapse of Enron and the generally declining strength of independent power developers following that collapse. It is FPL's customers that ultimately bear the risk of nonperformance of a project resulting from the financial instability of a developer.

Feasibility of licensing and construction plans is an assessment of the reasonableness of the timing of a proposal, given lead times required to site, license, and construct a power plant, and considering the possibility of delay or cancellation resulting from opposition or any other factor. For example, the possibility of delay in licensing and construction is greater for a nuclear plant than a gas turbine. As another example, a combined cycle not "fully committed" to serving retail load might fact greater difficulty in securing a determination of need than a fully committed plant. Again, FPL's customers bear the risk associated with any potential delay.

Delivery risk related to firmness of fuel supply, the construction schedule, and the experience of the seller relate to an assessment of whether a proposed project will deliver power on schedule and reliably. Firmness of fuel supply relates to reliability of the electricity from a facility. A proposed unit that offers power without firm fuel suppliers, for example a gas-fired unit without firm gas transportation, is a higher risk than that same facility with firm transportation. The experience of the seller must also be assessed to assure that the proposed. A proposal offered by a developer that has not shown a history of bringing projects in on time would obviously be less favored than one from a developer with a strong project management record.

The degree of control offered to FPL, including dispatchability and rights to sell power from a project, involves a comparison of a proposed contractual structure to the characteristics FPL would have with its self-built units. For example, an FPL-owned unit is fully controllable by FPL' system operator, within technology limits, so that the unit can be turned on or off, up or down, to meet system requirements. When the unit is not needed to meet system native load requirements, it is available to provide power for system sales, providing gains back to FPL's customers.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been discussed, the near - term elements of FPL's capacity additions are the repowering of its Fort Myers and Sanford plants, the addition of new combustion turbines (CT's) at Fort Myers, and a number of firm capacity, short-term purchases. The incremental capacity from the two repowering projects comes from the addition of new CT's and heat recovery steam generators (HRSG's). FPL acquired the repowering-related CT's, plus the other CT's for Fort Myers, and the HRSG's through a bid process which combined cost and performance considerations. The firm capacity short-term purchases were acquired through negotiations.

The 2005 capacity addition decision was arrived at after evaluating 81 bids received in response to a capacity Request for Proposals (RFP) issued by FPL in mid-2001. (Please see Section III for a further discussion of the RFP effort.)

The later (2007 – on) capacity additions projected in FPL's Site Plan document will likely be carried out following the issuance of a similar capacity solicitation to potential suppliers at an appropriate time, if that approach represents the best vehicle to offer the lowest cost new generating capacity.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

FPL's plans do not include any new or upgraded transmission lines during the 2002 – 2011 time period which would need to be certified under the Transmission Line Siting Act (403.52 – 403.536, F.S.)

CHAPTER VI

Summary of Required Schedules

2010	22,687	152	22,535	0	844	410	548	185	20,700
2011	23,106	152	22,954	0	844	410	548	185	21,119

Historical Values (1992 - 2001):

Cols. (2) - (4) are actual values for historical summer peaks As such, they incorporate the effects of conservation (Cols. (7&9)), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand Cols. (5) - (9) represent actual DSM capabilities starting from January 1988.
Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes GS-LC, CDR and GSD-LC.
Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: (10) = (2) -(6) -(8).

Projected Values (2002 - 2011):

Cols. (2) - (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2001 are incorporated into the forecast.
Cols. (5) - (9) represent all incremental conservation and cumulative load control. These values are projected August values and are based on projections with a 1/2001 starting point.
Col (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col (10) is derived by using the formula: (10) = (2) - (5) - (6) - (7) - (8) - (9).

2010	125,448	830	262	124,367	1,081	7,631	124,356	63.1%
2011	127,512	830	262	126,432	1,081	7,149	126,420	63.0%

Historical Values (1992 - 2001):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: (2) =(3) + (4) + (8).
Cols. (3) & (4) are DSM values starting in January, 1988 through 2001 which contributed to the values in Cols (5) - (9).
Cols. (5) & (6) are a breakdown of Net Energy For Load in Col (2) into Retail and Wholesale .
Col (9) is calculated using Col. (8) from this page and Col. (2), "Total", from Schedule 3.1. (9) = ((8)*1000) / ((2) * 8760)

Projected Values (2002 - 2011):

Col. (2) represents Net Energy for Load w/o DSM values. The values are calculated using the formula. (2) =(3) + (4) + (8)
Cols. (3) - (4) are forecasted values of the reduction on sales from incremental conservation.
Cols. (5) & (6) are a breakdown of Net Energy For Load in Col (2) , into Wholesale and Retail .
Col. (9) is calculated using Col. (2) from this page and Col. (2), "Total", from Schedule 3.1. (9) = ((8)*1000) / ((2) * 8760)

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated. All values are Summer net MW

2/ Total Capacity Available=Col.(2) + Col.(3) - Col.(4) + Col.(5).

3/ These forecasted values reflect the Most Likely forecast without DSM.

4/ The MW shown represent cumulative load management capability plus incremental conservation from 1/99 - on. They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based.

5/ Margin (%) Before Maintenance = Col.(10) / Col.(9)

6/ Margin (%) After Maintenance =Col.(13) / Col.(9)

											2005 Total:	**0**	**789**	

1)The Winter Total MW value consists of all generation additions and changes achieved by January The Summer Total MW value consists of all generation additions and changes achieved by July All other MW will be picked up in the following year This is done for reserve margin calculation

2) All MW differences are calculated based on using IRP 2001 Submittal (for the year 2001) as the base for all other years

3) The values shown reflect the schedule for the repowering of Sanford Unit # 4 that was used in FPL's 2001 resource planning work That schedule has recently changed Please refer to Section III A, "Step 1" for more information

4) Negative values for Sanford and Ft Myers reflect the existing steam units being temporarily out of service during that seasonal period for repowering efforts

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1)	**Plant Name and Unit Number:**		Fort Myers Repowering
(2)	**Capacity**		
	a. Summer	929	MW Incremental (1473 MW Total After Repowering)
	b. Winter	1,073	MW Incremental (1617 MW Total After Repowering)
(3)	**Technology Type:**		Combined Cycle
(4)	**Anticipated Construction Timing**		
	a. Field construction start-date:	1999	
	b. Commercial In-service date:	2002	
(5)	**Fuel**		
	a. Primary Fuel		Natural Gas
	b. Alternate Fuel		None
(6)	**Air Pollution and Control Strategy:**		Natural Gas, Dry Low NO_x Combustors
(7)	**Cooling Method:**		Once-through Cooling w/ Helper Cooling Tower
(8)	**Total Site Area:**	460	Acres
(9)	**Construction Status:**	V	(Under Construction > 50% Complete)
(10)	**Certification Status:**	V	(Under Construction > 50% Complete)
(11)	**Status with Federal Agencies:**	V	(Under Construction > 50% Complete)

(12) **Projected Unit Performance Data:**

Planned Outage Factor (POF):	3%	
Forced Outage Factor (FOF):	1%	
Equivalent Availability Factor (EAF):	96%	
Resulting Capacity Factor (%):	Approx. 90%	(First Year)
Average Net Operating Heat Rate (ANOHR):	6,830	Btu/kWh

(13) **Projected Unit Financial Data, *,**,*****

Book Life (Years):	25	years
Total Installed Cost (In-Service Year $/kW):	559	
Direct Construction Cost ($/kW):		
AFUDC Amount ($/kW):		
Escalation ($/kW):		
Fixed O&M ($/kW -Yr.): (2001$/kW-Yr)	13.45	
Variable O&M ($/MWH): (2001 $/MWH)	0.37	
K Factor:	1.5395	

* $/kW values are based on incremental Summer capacity.
** Note that cost values shown do not reflect the FPL system benefits which result from efficiency improvements to the existing steam capacity at the site.
*** Fixed O&M includes capital replacement.

NOTE: Total installed cost already includes escalation and AFUDC.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1)	**Plant Name and Unit Number:**		Sanford Unit 4 Repowering
(2)	**Capacity**		
	a. Summer	567	MW Incremental (957 MW Total After Repowering)
	b. Winter	671	MW Incremental (1065 MW Total After Repowering)
(3)	**Technology Type:**		Combined Cycle
(4)	**Anticipated Construction Timing**		
	a. Field construction start-date:	2000	
	b. Commercial In-service date:	2002	
(5)	**Fuel**		
	a. Primary Fuel		Natural Gas
	b. Alternate Fuel		None
(6)	**Air Pollution and Control Strategy:**		Natural Gas, Dry Low NO_x Combustors
(7)	**Cooling Method:**		Cooling Pond
(8)	**Total Site Area:**	1,718	Acres
(9)	**Construction Status:**	U	(Under Construction $\leq$ 50% Complete)

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Fort Myers Repowering

The transmission line work for this project has been completed.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Sanford Repowering

The transmission line work for this project has been completed.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Ft. Myers: 2 CT's

(1)	Point of Origin and Termination:	From Ft. Myers GT Collector bus – To Orange River
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	2.5 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: January 1, 2003 End date: May 1, 2003
(7)	Anticipated Capital Investment:	$1,050,000
(8)	Substations:	Orange River and Ft. Myers GT collector bus
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Manatee CC Unit

(1)	Point of Origin and Termination:	Manatee – Johnson
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	18 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: June 1, 2004 End date: June 1, 2005
(7)	Anticipated Capital Investment:	$12,700,000
(8)	Substations:	Manatee and Johnson
(9)	Participation with Other Utilities:	None

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

Martin CT – to - CC Conversion

(1)	Point of Origin and Termination:	Martin – Indiantown #2
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned & New acquisitions
(4)	Line Length:	12.9 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBA End date: TBA
(7)	Anticipated Capital Investment:	$9,400,000
(8)	Substations:	Martin 230kV and Indiantown
(9)	Participation with Other Utilities:	None

(1)	Point of Origin and Termination:	Indiantown – Bridge
(2)	Number of Lines:	1
(3)	Right-of-way	FPL Owned
(4)	Line Length:	10.0 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: TBA End date: TBA
(7)	Anticipated Capital Investment:	$10,300,000
(8)	Substations:	Indiantown and Bridge
(9)	Participation with Other Utilities:	None

Re: 2003 – 2012 Ten-Year Site Plan

Dear Ms. Bayó,

In accordance with Chapter 186 (Section 186.801 - Ten Year Plans) of the Florida Statutes, enclosed for filing are twenty-five (25) copies of Florida Power & Light Company's 2003- 2012 Ten-Year Power Plant Site Plan.

If you have any questions, please do not hesitate to contact me at (305) 552-4332 or Millie Gonzalez at (305) 552-2279.

Sincerely,

Anne M. Grealy

Overview of The Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten - Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and a disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (FAC).

This Ten - Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) planning analyses that were carried out in 2002 and that were on-going in the first quarter of 2003. The forecasted information presented in this plan addresses the 2003 – 2012 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten - year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as part of the Florida site certification process, or through other proceedings and filings.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, especially new power plants, as determined in FPL's IRP work in 2002 and early 2003.

Chapter IV – Environmental and Land Use Information

This chapter discusses various environmental information as well as preferred and potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional specific information which is to be included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2003 Ten - Year Power Plant Site Plan (Site Plan) addresses FPL's plans to increase its electric generation capability as part of its efforts to meet its projected incremental resource needs for the 2003 – 2012 time period.

FPL's total generation capability is projected to significantly increase during the 2003 – 2012 time period as shown in Table ES.1. This table also shows the resulting projected Summer and Winter reserve margins for FPL over this ten-year time horizon.

Table ES.1 reflects FPL's on-going project to repower FPL's existing Sanford Unit # 4 (two existing units at Fort Myers and another existing unit at Sanford have recently been repowered), planned changes to existing generation units (due to unit overhauls, etc.), and scheduled changes in the delivered amounts of purchased power. The table also reflects the planned additions of new generating units. Although not specifically shown in this table, FPL's approved DSM goals are assumed to be implemented on schedule.

The amount of new generating capacity that will be added is driven in part by the outcome of the Florida Public Service Commission docket No. 981890-EU. This docket ended with a stipulated agreement that resulted in FPL, along with Tampa Electric Company and Florida Power Corporation, switching from a minimum reserve margin planning criterion of 15% to one of 20% beginning with the Summer of 2004. As a consequence, FPL is now planning to add significantly more new generation capacity than was shown in its Site Plans filed prior to this agreement.

As shown in Table ES.1, FPL is adding two new combustion turbines (CT's) at FPL's existing Fort Myers plant site in 2003. Also during 2003, FPL will be completing its work to repower its existing Sanford Unit # 4.

FPL has also secured capacity through early 2007 through a number of short-term, firm capacity purchases from utilities and other entities. An additional short-term, firm purchase for 2004 will replace a previous purchase agreement for this time frame that was recently terminated.

In 2005, FPL will be adding a large (1,107 Summer MW) new combined cycle (CC) unit at its existing Manatee plant site. Also in 2005, the two combustion turbines (CT's) that were added at FPL's existing Martin plant site in mid - 2001 will be converted into a 1,107

Summer MW CC unit by the addition of two additional CT's, heat recovery steam generators, and associated equipment. This conversion will add another 783 Summer MW of capability above the present capability of the existing two CT's. The additions for 2005 were selected as the best options among other FPL construction alternatives and numerous outside proposals received in response to two Request for Proposals (RFP's) FPL issued in August 2001 and April 2002, respectively. These two capacity additions were approved by the Florida Public Service Commission on November 19, 2002 and their applications for certification under the Florid Electric Power Plan Siting Act are pending.

In 2007, FPL projects a capacity need of approximately 1,050 MW of additional capacity. The results of FPL's on-going planning analyses through the first quarter of 2003 indicate that the best FPL construction option to meet this need is a new 1,107 MW (Summer) CC unit. A number of potential sites for such a unit are currently under study and these are presented in Chapter IV as a "Potential Site". FPL will continue to analyze these sites for a new CC unit, as well as other capacity options, for meeting its 2007 capacity need. FPL will inform the Florida Public Service Commission when a decision is made regarding how to best meet this need.

In regard to meeting FPL's projected capacity needs for 2008 through 2012, FPL currently projects the addition of three additional CC units: one each year in 2008, 2010, and 2012. Sites for these three additional CC units have not yet been selected. [1] These planned increases in electric generation capability will allow FPL to continue to maintain system reliability and integrity at a reasonable cost.

FPL's recent planning efforts have also identified two issues that are now receiving attention in FPL's ongoing resource planning work. Those two issues are: 1) the growing imbalance in Southeast Florida between regional load and generating capacity located within this region; and 2) maintaining/enhancing fuel diversity in the FPL system. FPL's approach to these two issues will be developed through on-going resource planning work.

[1] FPL's current planning studies have identified new combined cycle units as the generally preferred option to meet future load growth. However, this is subject to change. Repowering of existing FPL sites remains an alternative to new construction and FPL will continue to examine this, and other, options including solid fuel options.

Projected Capacity Changes and Reserve Margins for FPL [1]					
		Net Capacity Changes (MW)		FPL Reserve Margin (%)	
		Winter [2]	Summer [3]	Winter	Summer
2003	Sanford Repowering # 4: Second Phase [4]	---	957	18%	20%
	Combustion Turbines (2) Fort Myers [5]	---	298		
	Purchases [6]	1,097	(140)		
	Changes to existing Units	31	(32)		
2004	Combustion Turbines (2) Fort Myers [5]	366	---	27%	20%
	Purchases [6]	(156)	44		
	New Short-Term Purchase [7]	---	213		
	Changes to existing Units	72	283		
	Sanford Repowering # 4: Second Phase [4]	1,036	---		
2005	Changes to existing QF's	(10)	(10)	22%	23%
	Purchases [6]	(6)	(523)		
	Manatee Unit #3 Combined Cycle [8]	---	1,107		
	New Short-Term Purchase [7]	---	(213)		
	Conversion of MR #8 CT's to CC [8]	(363)	783		
2006	Manatee Unit #3 Combined Cycle [8]	1,201	---	28%	20%
	Conversion of MR #8 CT's to CC [8]	1,198	---		
	Changes to existing QF's	(133)	(133)		
	Purchases [6]	(520)	---		
2007	Purchases [6]	---	(474)	25%	20%
	Unsited Combined Cycle # 1 [8]	---	1,107		
2008	Purchases [6]	(474)	---	26%	24%
	Unsited Combined Cycle # 1 [8]	1,209	---		
	Unsited Combined Cycle # 2 [8]	---	1,107		
2009	Unsited Combined Cycle # 2 [8]	1,209	---	29%	21%
	Changes to existing QF's	---	(51)		
2010	Unsited Combined Cycle # 3 [8]	---	1,107	26%	23%
	Changes to existing QF's	(51)	(44)		
2011	Unsited Combined Cycle # 3 [8]	1,209	---	29%	20%
	Changes to existing QF's	(89)	(45)		
2012	Unsited Combined Cycle # 4 [8]	---	1,107	26%	22%
	TOTALS =	6,827	6,449		

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedule 7 & 8 respectively.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) The second phase of the repowering consists of integrating the combustion turbines, heat recovery steam generators, and steam turbines.

(5) The two CT's at Fort Myers are scheduled to be in-service in the Spring of 2003. Therefore, the CT's are included in the 2003 Summer reserve margin calculation and are included in the 2004 - on reserve margin for Summer and Winter.

(6) These are firm capacity purchases. See Section I.D and III.A. for more details.

(7) Negotiations are currently underway between FPL and several parties to secure this short - term capacity.

(8) All new combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

Table ES.1

CHAPTER 1

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 7.8 million people. FPL served an average of 4,019,805 customer accounts in thirty-five counties during 2002. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management, and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville. The current generating facilities consist of four nuclear steam units, three coal units, eight combined cycle units, eighteen fossil steam units, fifty combustion gas turbines, and five diesel units. The location of these units is shown on Figure I.A.1.

The bulk transmission system is composed of 1,105 circuit miles of 500 Kilovolt (KV) lines (including 75 miles of 500 KV lines [two 37-1/2 mile lines] between Duval Substation and the Florida-Georgia state line, which are jointly owned with Jacksonville Electric Authority) and 2,702 circuit miles of 230 KV lines. The underlying network is composed of 1,630 circuit miles of 138 KV lines, 718 circuit miles of 115 KV lines, and 178 circuit miles of 69 KV transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 515 substations.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

Capacity Resources
(as of December 31, 2002)

☐ Non-FPL Territory

FPL Interconnection Diagram

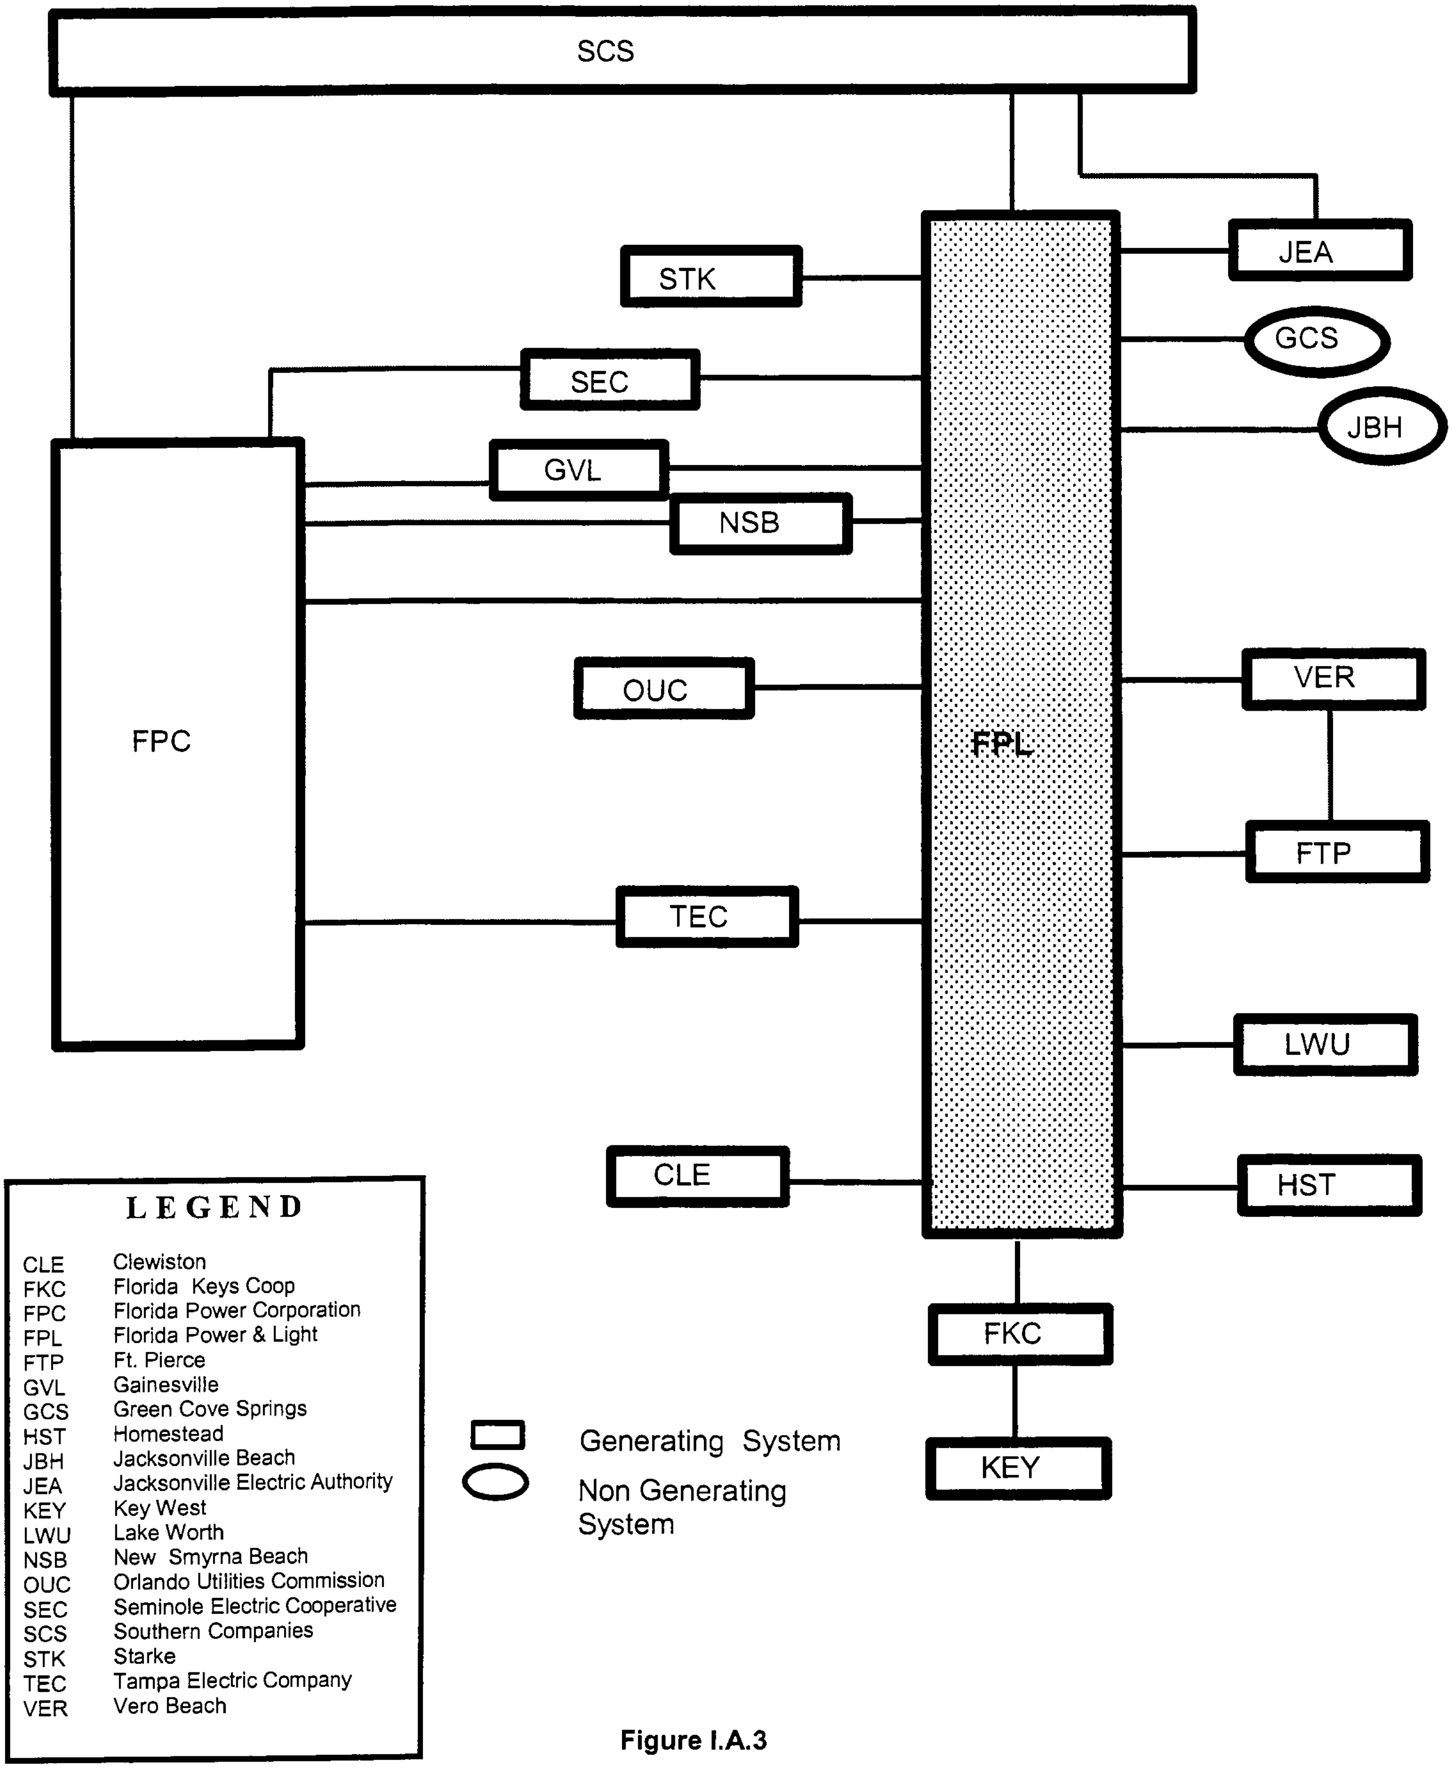

Figure I.A.3

I.B Non-Utility Generation

Non-utility generation is an important part of FPL's resource mix. FPL currently has contracts with seven cogeneration/small power production facilities to purchase firm capacity and energy. A listing of these facilities appears in Table I.B.1. In addition, FPL purchases as-available (non-firm) energy from several cogeneration facilities and small power production facilities as shown in Table I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Florida Power & Light Company Firm Capacity and Energy Contracts with Cogeneration/Small Power Production Facilities

Table I.B.2

I.C. Demand Side Management (DSM)

FPL's DSM activities continue what has been FPL's practice since 1978 of encouraging cost-effective conservation and load management. FPL's DSM efforts through 2002 have resulted in a cumulative Summer peak reduction of approximately 2,923 MW at the meter and an estimated cumulative energy saving of 5,270 GWH at the meter.

FPL's current DSM Plan was approved by the Florida Public Service Commission in late 1999 and reflects FPL's new DSM Goals for the 2000-2009 time frame. FPL's 2003 resource plan, and the schedule for new generation additions presented in this document, are based on these approved DSM levels.

I.D. Purchased Power

Purchased power remains an important part of FPL's resource mix. FPL has a unit power sales (UPS) contract to purchase 929 MW, with a minimum of 380 MW, of coal-fired generation from the Southern Company. In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 381 MW (Summer) and 390 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Unit Nos 1 and 2 (FPL also has ownership interest in these units; that ownership amount is reflected in FPL's installed capacity shown on Schedule 1).

Finally, FPL has firm capacity purchase contracts through early 2007. These firm capacity purchase contracts are with a variety of suppliers. Table I.D.1 presents the Summer and Winter MW resulting from all firm purchased power contracts through the year 2012.

	FPL's Purchased Power MW (1)							
	UPS		SJRPP		Other Firm Capacity Purchases		Total	
Year	Winter	Summer	Winter	Summer	Winter	Summer	Winter	Summer
2002 (2)	929	929	390	381	50	1093	1369	2403
2003	929	929	390	381	1156	953	2475	2263
2004	929	929	390	381	1000	1210	2319	2520
2005	929	929	390	381	994	474	2313	1784
2006	929	929	390	381	474	474	1793	1784
2007	929	929	390	381	474	0	1793	1310
2008	929	929	390	381	0	0	1319	1310
2009	929	929	390	381	0	0	1319	1310
2010	929	929	390	381	0	0	1319	1310
2011	929	929	390	381	0	0	1319	1310
2012	929	929	390	381	0	0	1319	1310

Note:

(1) Total reflects total resource entitlements resulting from existing agreements between FPL, Southern Companies, JEA, and from new firm purchase agreements. In addition, the UPS values reflect a projected extension or renegotiation of the UPS contracts beyond their current expiration date.

(2) Values for 2002 are actual.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are developed on an annual basis for resource planning work at FPL. These forecasts are a key input to the models used to develop the Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

The primary drivers to develop these forecasts are demographic trends, weather, economic conditions, and prices of electricity. In addition, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from NOAA, and inputs from FPL's own customer service planning areas. In the area of demographics, population trends by county, plus housing characteristics such as housing starts, housing size, and vintage of homes are assessed.

Forecasts for electric usage in the residential and commercial classes include end-use information such as appliance saturation studies, efficiencies, and intensity of energy use. In addition to these inputs, residential forecasts also make use of household characteristics such as ages of members in households, number of members in households, and income distributions.

The projections for the National and Florida economy are obtained from Global Insight, formerly know as DRI - WEFA. Population projections for the counties served by FPL are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. In addition, FPL actively participates with local development councils and universities to obtain their assessments of the local economy, specifically in the area of expansion of new businesses and retention of the current business base. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is a key factor that affects the company's sales and peak demand. Weather variables are used in the forecasting models for energy sales and peak demand. There are two sets of weather variables developed and used in forecasting models:

1. Cooling and Heating Degree-Days are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric heaters. A composite temperature is derived using hourly temperatures across FPL's service territory (Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained) weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Days which are based on starting point temperatures of 72°F and 66°F, respectively. Similarly, the maximum and minimum of the composite temperature is used for the Summer and Winter peak models.

II.A. Long-Term Sales Forecasts

Long-term forecasts of electricity sales are developed for each revenue class for the forecasting period of 2003 - 2022 and are adjusted to match the Net Energy for Load (NEL) forecast. The results of these sales forecasts for the years 2003 - 2012 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical tool MetrixND. The methodologies used to develop sales forecasts for each jurisdictional revenue class are outlined below.

The first five years of the forecasts are developed using monthly models for Net Energy for Load and energy sales by class.

1. Residential Sales

Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted. Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, Florida per capita income, and Cooling and Heating Degree-Days as explanatory variables. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. The Cooling Degree-Days variable is multiplied by the level of air conditioning saturation and the Heating Degree-Days variable is multiplied by the level of electric heating saturation. To capture economic conditions the model includes Florida's per capita income. The degree of economic prosperity can, and does, affect residential electricity sales. For the short-term period (first five years), an econometric model is developed using monthly data. The monthly model is a function of the same variables such as Cooling Degree-Days, Heating Degree-Days, price of electricity, Florida's per capita income, and a dummy variable for the months of April, May, and October.

2. Commercial Sales

The commercial sales forecast is also developed using a regression model for the long-and short-term. Commercial sales are a function of the following variables: Florida's commercial employment, commercial real price of electricity, Cooling Degree-Days and an autoregressive term. Florida's commercial employment is used to capture the economic activity in FPL's service territory. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree-Days are used to capture weather-sensitive load in the commercial sector. The first five years of the forecast are developed from a monthly model using the same explanatory variables, and for the following years, growth rates from the annual model are applied.

3. Industrial Sales

Industrial sales are forecasted through a linear multiple regression model using Florida manufacturing employment, the price of electricity, and a dummy variable for the economic recessions. Energy sales in this revenue class are primarily due to manufacturers; therefore, employment in this sector is a key variable in capturing the economic activity. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. For the short-term period (first five years), an econometric model is developed using monthly data. The monthly model is a function of the same variables such as Florida manufacturing employment, Cooling Degree-Days, price of electricity, and an autoregressive term. For the following years, growth rates from the annual model are applied.

4. Other Public Authority Sales

At present, this class consists of sports fields and one government account. The forecast for this class is based on historical knowledge of its characteristics.

5. Street & Highway Sales and Railroad & Railways Sales

The forecast for Street and Highway sales is developed by first assuming a constant use per customer and then multiplying that value by the number of projected customers.

The forecast of sales to Railroad & Railways is based on historical knowledge of its characteristics. This class consists of Miami-Dade County's Metrorail system.

6. Resale Sales

Resale (Wholesale) customers are composed of municipalities and/or electric cooperatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Contract Rate

Currently, there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of Key West, Florida (City of Key West), Miami-Dade County, and FMPA. Sales to the Florida Keys are forecasted using a regression model. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor. Miami-Dade County sells 60 MW to Florida Power Corporation. Line losses are billed to Miami-Dade under a wholesale contract. The forecast is calculated based on assumptions about the magnitude of line losses, the sales monthly capacity factor, and the number of hours in a particular month. FMPA has contracted for delivery of 75 MW through October 2007.

Total Sales

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual Net Energy for Load (NEL).

II.B. Net Energy for Load

An annual econometric model is developed to produce a Net Energy for Load (NEL) forecast. The key inputs to the model are: the price of electricity, Heating and Cooling Degree-Days, Florida Non-Agricultural Employment, and an autoregressive term. The monthly model is similar, except the economic variable utilized is Florida's per capita income since the model is estimated on a per customer basis. Like the sales forecasts, the first five years are obtained from the short-term model, and forecasts for subsequent years are generated using the growth rates from the annual model.

Once an annual NEL forecast is obtained using the above-mentioned methodology, the results are then compared for reasonableness to the NEL forecast generated using the total sales forecast. The sales by class are then adjusted to match the NEL from the annual NEL model.

The forecasted NEL values for 2003 – 2012 are presented in Schedule 3.3, that appears at the end of this chapter.

II.C. System Peak Forecasts

The rate of absolute growth in FPL system load has been a function of a larger customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the Peak Forecast models to capture these behavioral relationships.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2003 – 2012 are presented in Schedules 3.1 and 3.2 as well as in Schedules 7.1 and 7.2.

System Summer Peak

The Summer peak forecast is developed using an econometric model. The model is a per customer model that includes: the total number of FPL's customers, the price of electricity, Real Florida income as an economic driver, and the maximum temperature as a weather variable. Also included in the model is an autoregressive term.

System Winter Peak

Like the system Summer peak model, the Winter peak model is also an econometric model. The Winter peak model is a per customer model which consists of three weather-related variables: (1) the minimum Winter day temperature, (2) a weather term, which is a ratio of heating saturation and minimum Winter day temperature, and (3) Heating Degree-Hours for the prior day until 9:00 a.m. of the peak day. In addition, the model also uses an economic variable, Real Florida Income. A dummy variable, which is used to capture the effects of larger homes, is multiplied by the minimum temperature.

Monthly Peak Forecasts

Monthly peaks for the 2003-2022 period are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peak (Summer = April-October, Winter = November-March.)

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.D. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2003 – 2022 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. These daily load shapes are ranked and used with forecasted monthly peaks, NEL, and calendars in developing an hourly forecast. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

Historical Values (1993 - 2002):

Cols. (2) - (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Cols. (7&9)), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.
Cols. (5) - (9) represent actual DSM capabilities starting from January 1988.
Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes GS-LC, CDR and GSD-LC.
Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula:Col. (10) =Col.(2) - Col.(6) - Col.(8).

Projected Values (2003 - 2012):

Cols. (2) - (4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2002 are incorporated into the forecast.
Cols. (5) - (9) represent all incremental conservation and cumulative load control. These values are projected August values and are based on projections with a 1/2002 starting point.
Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990's and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of potential new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2002 and early 2003 planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans;

Step 3: Determine the economics for the total utility system with each of the competing options and resource plans; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

Overview of FPL's IRP Process

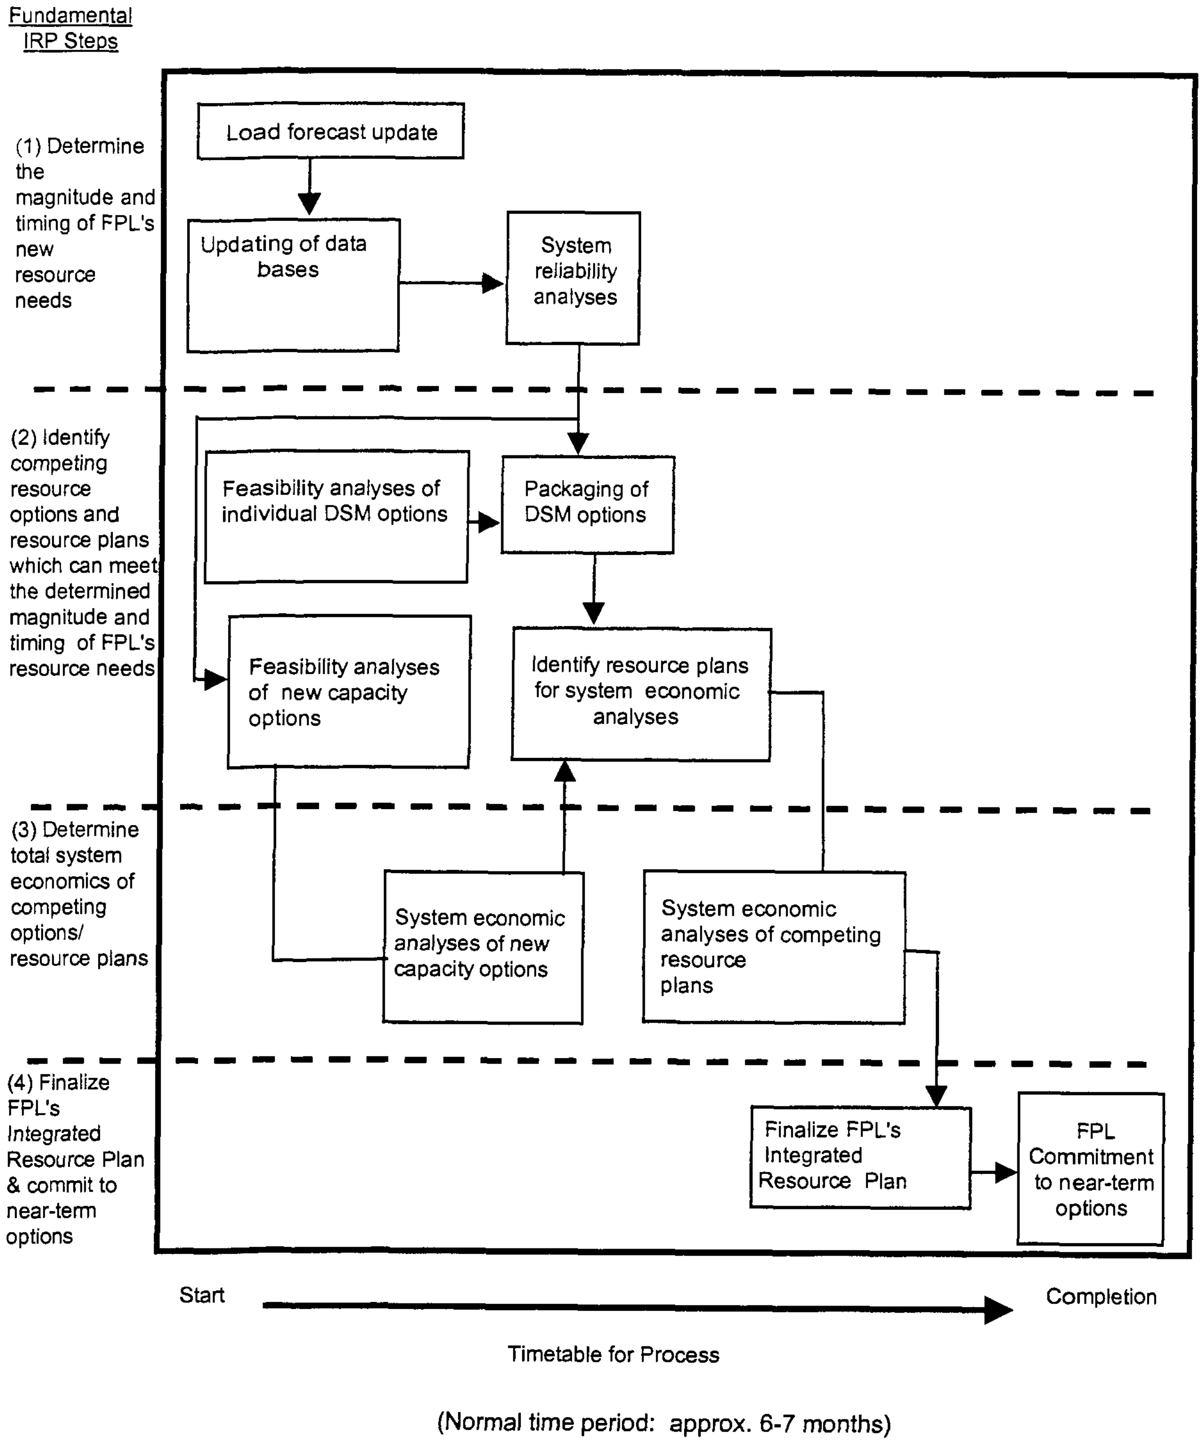

Figure III.A.1

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps – determining the magnitude and timing of FPL's resource needs – is essentially a determination of how many megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions are needed. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a reliability assessment for the utility system.

Step 1 starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information which is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. During its recent IRP work, FPL utilized four assumptions regarding near-term construction capacity additions, short-term, firm capacity purchase additions, long-term DSM implementation, and the projected extension or renegotiation of the UPS contracts.

The first of these assumptions is based on FPL's announced plans to add near-term capacity through various construction projects. These construction projects include the repowering of an existing unit and the addition of several new units. FPL committed in 1998 to repower both existing steam units at its Fort Myers plant site and two of the three existing steam units at its Sanford plant site. The Fort Myers repowering work is completed, as is the repowering work of one of the Sanford units. The repowering of the other Sanford unit (Unit # 4) will be completed by mid-2003. This Sanford repowering was a "given" in FPL's resource planning work.

Another part of FPL's construction capacity addition assumption was its previously announced decision to add two new CT's during 2003 at FPL's existing Fort Myers site. FPL's resource planning work assumed that this capacity addition would also be a "given".

The final part of FPL's construction capacity addition assumption was the addition of a new combined cycle (CC) unit at Manatee and the conversion of two existing CT's at Martin into a new combined cycle unit. Both additions are scheduled for mid-2005. Both capacity additions were approved by the Florida Public Service Commission in November 2002 after comparing them to 134 competing bids that were received in response to two Requests for Proposals (RFP's) that solicited bids for meeting FPL's 2005/2006 capacity needs.

The second of these assumptions involves short-term, firm capacity purchase additions. FPL decided through its 2000 resource planning work to secure an amount of purchase capacity for the next few years through short-term, firm capacity purchases. These firm capacity purchases are from a combination of utility and independent power producers. The total capacity and duration of these purchases have changed somewhat from what was presented in last year's Site Plan. These changes are due to two factors: new information regarding transmission limitations for several of the new capacity purchases, and a decision to secure additional short-term purchase capacity for 2004 due to the termination of one of the previously signed short-term purchases. The annual total capacity values for these purchases are presented in Table I.D.1. These purchase amounts were also assumed as a "given" in FPL's resource planning work.

The third of these assumptions involves DSM. Since 1994, FPL's resource planning work has used the DSM MW called for in FPL's approved DSM goals as a "given" in its analyses. This was again the case in FPL's most recent planning work, as its approved DSM goals through the year 2009 were taken as a "given".

The fourth of these assumptions is a projected extension or renegotiation of the UPS purchases that are currently scheduled to end in 2010. No final decision has been reached on this matter, but FPL has initiated discussions with Southern Company regarding a possible extension or renegotiation of these purchases. The inclusion, for planning purposes, of the assumption that these coal-by-wire purchases will continue beyond the current expiration date reflects an interest in maintaining/enhancing fuel diversity in FPL's system.

The first place in which these assumptions and much of the other updated information and assumptions are used is the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 15% (FPL applies this to both Summer and Winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry. The reserve margin criterion increases from 15% to 20% starting in mid-2004 due to a voluntary agreement reached among FPL, FPC, and TECO, and accepted by the FPSC in the FPSC's Docket No. 981890-EU.

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of how well a generating system can meet its native load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as: unit numbers and sizes (i.e., two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time); and the value of being part of an interconnected system.

Therefore, probabilistic methodologies have been used to provide additional information on the reliability of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss-of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using the Tie Line Assistance and Generation Reliability (TIGER) model.

The end result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. This information is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans Which can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analysis of new capacity options are carried out to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs.

The individual new capacity options are then "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using dynamic programming techniques. For planning purposes, only FPL construction options were included in FPL's most recent planning analyses.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs were identified. These resource plans were then compared on an economic basis.

Step 3: Determining the Total System Economics:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for comparing the system economics of these resource plans. FPL combines the resource options into resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI) and Stone & Webster Management Consultants, Inc. The EGEAS model is also used to perform the basic economic analyses of the resource plans.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases such as existed for FPL's most recent planning work in which the DSM contribution was taken as a "given" and the only competing options were new generating units, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans were evaluated on a present value system revenue requirement basis.

The basic economic analyses carried out with the EGEAS model focus on the capital and operating costs of new capacity options plus the impact these new capacity options have on FPL's system fuel costs.

At the conclusion of the analyses carried out in Step 3, a determination of FPL's preferred resource plan was made.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps activities were evaluated by FPL management and a decision was made as to what FPL's current resource plan would be. This plan is presented in the following section.

III.B Incremental Resource Additions

FPL's projected incremental generation capacity additions/changes for 2003 through 2012 are depicted in Table III.B.1 (The planned DSM additions are shown separately in Table III.C.1). These capacity additions/changes will result from a variety of actions including: changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, repowering of an existing steam unit, projected construction of new units, and conversion of CT's into a CC unit.

As shown in Table III.B.1, the bulk of the capacity additions are made up of the following items: a completion of the repowering of FPL's Sanford Unit # 4 that is projected to be completed by the Summer, 2003; the construction of two new CT's by mid – 2003 at FPL's existing Fort Myers site; the addition of one or more new short-term purchases for 2004 that replaces a previous purchase agreement; the conversion of two CT's into a larger CC unit in 2005 at FPL's Martin site; the addition of a new CC unit, also in 2005, at FPL's Manatee site; and the construction of four additional CC units in the 2007 through 2012 time frame. Sites for these four CC units that are currently projected to be added in the 2007 through 2012 timeframe have not yet been selected.

Projected Capacity Changes and Reserve Margins for FPL [1]			
		Net Capacity Changes (MW)	
		Winter [2]	***Summer*** [3]
2003	Sanford Repowering # 4: Second Phase [4]	---	957
	Combustion Turbines (2) Fort Myers [5]	---	298
	Purchases [6]	1,097	(140)
	Changes to existing Units	31	(32)
2004	Combustion Turbines (2) Fort Myers [5]	366	---
	Purchases [6]	(156)	44
	New Short-Term Purchase [7]	---	213
	Changes to existing Units	72	283
	Sanford Repowering # 4: Second Phase [4]	1,036	---
2005	Changes to existing QF's	(10)	(10)
	Purchases [6]	(6)	(523)
	Manatee Unit #3 Combined Cycle [8]	---	1,107
	New Short-Term Purchase [7]	---	(213)
	Conversion of MR #8 CT's to CC [8]	(363)	783
2006	Manatee Unit #3 Combined Cycle [8]	1,201	---
	Conversion of MR #8 CT's to CC [8]	1,198	---
	Changes to existing QF's	(133)	(133)
	Purchases [6]	(520)	---
2007	Purchases [6]	---	(474)
	Unsited Combined Cycle # 1 [8]	---	1,107
2008	Purchases [6]	(474)	---
	Unsited Combined Cycle # 1 [8]	1,209	---
	Unsited Combined Cycle # 2 [8]	---	1,107
2009	Unsited Combined Cycle # 2 [8]	1,209	---
	Changes to existing QF's	---	(51)
2010	Unsited Combined Cycle # 3 [8]	---	1,107
	Changes to existing QF's	(51)	(44)
2011	Unsited Combined Cycle # 3 [8]	1,209	---
	Changes to existing QF's	(89)	(45)
2012	Unsited Combined Cycle # 4 [8]	---	1,107
	TOTALS =	6,827	6,449

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) The second phase of the repowering consists of integrating the combustion turbines, heat recovery steam generators, and steam turbines.

(5) The two CT's at Fort Myers are scheduled to be in-service in the Spring of 2003. Therefore, the CT's are included in the 2003 Summer reserve margin calculation and are included in the 2004 - on reserve margin for Summer and Winter.

(6) These are firm capacity purchases. See Section I.D and III.A. for more details.

(7) Negotiations are currently underway between FPL and several parties to secure this short - term capacity.

(8) All new combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

Table III.B.1

III.C Other Results of FPL's Recent Planning Work

In the course of FPL's 2002 and early 2003 planning efforts, two issues were identified that are now receiving attention in FPL's on-going resource planing work. Those two issues are: 1) the need to address the growing imbalance in Southeast Florida between regional load and generating capacity located within this region; and 2) the desire to maintain/enhance fuel diversity in the FPL system.

In regard to the first issue, currently there exists a significant imbalance between the very high peak load in the Southeast Florida region of FPL's service territory and the installed generating capacity in that region. Because of the continuing load growth in this region, the imbalance between generation and load will increase significantly during the next few years unless additional generation is sited in the Southeast Florida region.

If a majority of the generation capacity additions required to meet FPL system needs for 2007 and 2008 are not sited in Southeast Florida, FPL expects that in 2009 and 2010 it will have to either add generating capacity within this region, or add substantial amounts of transmission facilities that are likely to be costly to bring power generated outside the region into Southeast Florida in order to continue to reliably serve this load. At present, FPL believes that adding generation capacity within the region is the preferred approach.

The second issue, the desire to maintain/enhance fuel diversity in the FPL system, is not explicitly reflected in the resource plan presented in this Site Plan. The plan to meet capacity needs beyond 2007, reflected in the Tables and Schedules of this document, consists of the construction of three additional CC units in the 2008 through 2012 time frame at sites yet to be selected. However, these resources additions are subject to change.

FPL intends to identify and evaluate alternatives that would enhance fuel diversity in its capacity resource mix. These alternatives include: extending and/or expanding existing solid fuel-based power purchases such as the UPS contract, building new solid fuel-based generation capacity in FPL's system, obtaining access to non-traditional sources of natural gas, such as through suppliers who deliver natural gas to Florida from international sources of production, and maintaining the ability to utilize fuel oil at FPL's existing units. Therefore, the new gas-fired CC units currently shown as capacity additions for 2008, 2010, and 2012 are subject to change in the future as FPL evaluates the feasibility and cost-effectiveness of various alternatives to enhance fuel diversity.

FPL believes that the earliest that one of these alternatives to enhance fuel diversity, adding new solid fuel-based generating capacity, could be permitted and built in Florida is 2009. In addition, FPL believes it is more likely that such a unit would be sited at some site north of the Southeast Florida region due to permitting and fuel transportation considerations.

As a result, FPL believes that the time and location aspects of these two issues will likely result in an approach in which FPL attempts to address the Southeast Florida imbalance first when it finalizes plans for meeting its 2007 and/or 2008 need. Such an approach would accomplish two things. First, it would address the immediate concern regarding this growing regional imbalance. Second, to the extent the 2007 and/or 2008 capacity additions effectively address the Southeast Florida imbalance concern, solid fuel-based capacity additions north of the Southeast Florida region would be more feasible and cost-effective.

FPL's approach to these two issues will be developed through on-going resource planning work.

III.D Demand Side Management (DSM)

1. FPL's Current DSM Programs

FPL's currently approved DSM programs are summarized as follows:

Residential Conservation Service: This is an energy audit program designed to assist residential customers in understanding how to make their homes more energy-efficient through the installation of conservation measures/practices.

Residential Building Envelope: This program encourages the installation of energy-efficient ceiling insulation in residential dwellings that utilize whole-house electric air conditioning.

Duct System Testing and Repair: This program encourages demand and energy conservation through the identification of air leaks in whole-house air conditioning duct systems and by the repair of these leaks by qualified contractors.

Residential Air Conditioning: This is a program to encourage customers to purchase higher efficiency central cooling and heating equipment.

Residential Load Management (On-Call): This program offers load control of major appliances/household equipment to residential customers in exchange for monthly electric bill credits.

New Construction (BuildSmart): This program encourages the design and construction of energy-efficient homes that cost-effectively reduce coincident peak demand and energy consumption.

Business Energy Evaluation: This program encourages energy efficiency in both new and existing commercial and industrial facilities by identifying DSM opportunities and providing recommendations to the customer.

Commercial/Industrial Heating, Ventilating, and Air Conditioning: This program encourages the use of high-efficiency heating, ventilation, and air conditioning (HVAC) systems in commercial/industrial facilities.

Commercial/Industrial Efficient Lighting: This program encourages the installation of energy-efficient lighting measures in commercial/industrial facilities.

Business Custom Incentive: This program encourages commercial/industrial customers to implement unique energy conservation measures or projects not covered by other FPL programs.

Commercial/Industrial Load Control: This program reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

Commercial/Industrial Demand Reduction: This program (which started in 2002) is similar to the Commercial/Industrial Load Control mentioned above by continuing the objective to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits.

Commercial/Industrial Building Envelope: This program encourages the installation of energy-efficient building envelope measures such as window treatments and roof/ceiling insulation for commercial/industrial facilities.

Business On Call: This program offers load control of central air conditioning units to both small, non-demand-billed and medium, demand-billed commercial/industrial customers in exchange for monthly electric bill credits.

2. Research and Development

FPL's DSM Plan continues to support research and development activities. Historically, FPL has performed extensive DSM research and development. FPL will continue such activities not only through its Conservation Research and Development program, but also through individual research projects. These efforts will examine a wide variety of technologies that build on prior FPL research where applicable and will expand the research to new and promising technologies as they emerge.

Conservative Research and Development Program

FPL's Conservation Research and Development Program is designed to evaluate emerging conservation technologies to determine which are worthy of pursuing for program development and approval. FPL has researched a wide variety of technologies and from that research has been able to develop new programs such as Residential New Construction, Commercial/Industrial Building Envelope, and Business On Call.

Low Income Weatherization Retrofit Project

This R&D project is investigating cost-effective methods of increasing the energy efficiency in the homes of FPL's low-income customers. The research project addresses the needs of low-income housing retrofits by providing monetary incentives to various housing authorities including weatherization agency providers (WAPS), and non-weatherization agency providers (non-WAPS). These incentives are used by the housing authorities to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting. FPL either conducts a home energy survey, trains housing authority employees to perform FPL home energy surveys, accepts the National Energy Audit (NEAT) (as supplemented to capture water heating recommendations not included in the NEAT audit), or approves similar FPL approved audits conducted by weatherization providers to determine the need for energy efficient retrofit measures for each home. FPL has designed the project so as to minimize extra work for the retrofit housing authorities.

Photovoltaic Research, Development and Education Project

Photovotaic (PV) roof-tile systems are a relatively new technology which directly replaces existing roofing materials such as shingles and standing-rib roofing with PV materials. These PV materials have the same waterproofing characteristics as conventional roofing materials. This project is consistent with the Federal Government's Million Solar Roofs Initiative. However, based on FPL's research to-date, a primary hurdle to the physical installation of PV systems, whether roofing materials or flat plate modules, is the lack of awareness, understanding, and acceptance by local building officials. For the most part, these officials are unclear about how these systems work and how to address these systems as part of the building, permitting, and inspection process. This creates barriers toward the use of this technology. As part of this project FPL will be holding workshops to address this issue.

Green Energy Project

Under this project, FPL is examining the feasibility of purchasing electric energy generated from new renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable sources. Customers who participate would then be charged higher premiums for utilizing electric energy derived from these sources.

FPL has determined that there is a level of customer acceptance and desire for a Green Power pricing program. A petition was submitted on May 3, 2002 for a declaratory statement (Docket No.020397 – EQ) asking the FPSC whether FPL may pay higher than avoided costs for energy from renewable sources devoted to a Green Power program. A favorable order was received on August 6, 2002. FPL is continuing its development of this project.

Real-Time Pricing

Although not part of FPL's approved DSM Plan, FPL continues to research new conservation/efficiency options such as real-time pricing. This option is an experimental service offering for large C/I customers that is designed to evaluate customer load response to hourly, marginal cost-based energy prices provided on a day-ahead basis.

On Call Pilot

In March 2003, FPL received FPSC Commission approval to perform a pilot for its On Call program. Under the pilot FPL will offer to new participants a residential load control service similar to the On Call Program at a reduced incentive level. The offering of.this pilot will allow FPL to test its market research data and gauge whether FPL can repackage its current residential load control service, minimize customer attrition, achieve current goals for residential load control, and, ultimately, change On Call incentive levels without damaging system reliability.

FPL will begin implementing the pilot in April 2003 and it will last up to 3 years.

3. FPL's DSM MW Goals

FPL's DSM implementation plan is designed to meet currently approved DSM goals for through 2009. The combined total residential and commercial/industrial Summer MW reduction values from FPL's DSM goals for 2000 – 2009 are presented in Table III. D.1. FPL's DSM efforts through 2002 have resulted in a cumulative Summer peak reduction of approximately 2,923 MW at the meter.

FPL's Summer MW Reduction Goals for DSM
(At the Meter)

Year	Goal Cumulative Summer MW
2000	122
2001	200
2002	269
2003	339
2004	410
2005	484
2006	554
2007	625
2008	697
2009	765

Table III.D.1

III.E Generation Additions From Independent Power Producers

As previously mentioned in Section III.A, FPL recently entered into a number of new short-term, firm capacity purchases that extend through early 2007. The capacity supplied by these purchases are summarized in Table I.D.1. The vast majority of the capacity from these purchases is from independent power producers.

Tables I.B.1 and Table I.B.2 present the previously contracted cogeneration/small power production facilities which are addressed in FPL's resource planning.

III.F Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents FPL's proposed future additions of 230 kV and 500 kV bulk transmission lines irrespective of whether they directly correspond to proposed generating facilities or whether they must be certified under the Transmission Line Siting Act.

List of Proposed Power Lines

(1) LINE OWNERSHIP	(2) TERMINALS (To)	(3) TERMINALS (From)	(4) LINE LENGTH CKT. MILES	(5) COMMERCIAL IN-SERVICE DATE (MO/YR)	(6) NOMINAL VOLTAGE (kV)	(7) CAPACITY (MVA)
FPL	Broward	Delmar	3	Jun-03	230	514
FPL	Charlotte	Whidden #3	29	Jun-03	230	1191
FPL	Cortez	Johnson	11	Jun-03	230	596
FPL/GPC *	Duval-Kingsland	Yulee-Oneil	7	Jun-03	230	478
FPL	Cedar	Lauderdale	1	Oct-03	230	514
FPL	Collier	Orange River	9	Nov-03	230	759
FPL	Coast	Peachland	7	Dec-03	230	596
FPL	Andytown	Pennsuco	2	Jun-04	230	508

FPL	Collier	Orange River	TBD	Dec-05	230	TBD

* GPC = Georgia Power Corporation
PGN = Progress Energy

Table III.F.1

In addition, there will be transmission facilities needed to connect several of FPL's committed capacity additions to the system transmission grid. These transmission facilities for the projected capacity additions at FPL's existing Fort Myers, Manatee, and Martin sites are described below. (No additional transmission facilities are needed for the repowering of Sanford Unit # 4).

Since the projected capacity additions for 2007 through 2012 are as-yet unsited, no transmission facilities information is provided. This information will be provided in future Site Plan documents once sites are selected.

III.F.1 Transmission Facilities at Fort Myers

The work required for the Fort Myers capacity expansion for two new CT units with the FPL grid is projected to be as follows:

I. Substation:

1. Build one collector bus with 2 breakers for each CT. Add another breaker to the collector bus for the station service transformer.
2. Add the two main step-up transformers (225MVA/each), one for each CT.
3. Add the station service transformer.
4. Connect the new Fort Myers collector bus to the Fort Myers 230kV switchyard.
5. Replace 4 breakers at the existing Fort Myers 230 kV switchyard.
6. Add relay and other protective equipment at Fort Myers switchyard.

II. Transmission:

1. All transmission work at Fort Myers is complete.

III.F.2 Transmission Facilities at Manatee

The work required for the new capacity addition at Manatee with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 6 breakers to connect the four CT's, and one ST.
2. Construct two string busses to connect the collectors and main switchyard.
3. Add five main step-up transformers (4-225MVA, 1- 450MVA) one for each CT, and one for the ST.
4. Add two breakers in bay # 6 to connect the collector bus at the Manatee switchyard.
5. Add two breakers in bay # 5 at the Manatee switchyard to connect the other collector bus.
6. Add relays and other protective equipment.
7. Upgrade 13-230kV circuit breakers to 2 cycle Independent Pole breakers at Manatee switchyard.
8. Upgrade the existing line terminal at Johnson to 3000 Amps.
9. Expand site and relay vault for two new line terminals at Manatee switchyard.

II. Transmission:

1. Upgrade the Calusa-Charlotte 230kV transmission line to 1875 Amps.
2. Upgrade the Johnson- Manatee 230kV transmission line to 2710 Amps.
3. Upgrade the Manatee-Ringling # 3 230kV transmission line to 2710 Amps.
4. Upgrade the Charlotte-Fort Myers # 2 230kV transmission line to 1565 Amps.

III.F.3 Transmission Facilities at Martin

The work required for the incremental capacity planned to be added at Martin (convert the existing two CT's to a new four-on-one combined cycle unit) with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing one collector buss with 4 breakers each to connect the two CT's and one ST.
2. Add one station service transformer in the existing CT yard.
3. Add three main step-up transformers (2-225 MVA, 450MVA) one for each CT, and one for the ST.
4. Add two breakers in bay # 3 to connect the collector bus in the main switchyard.
5. Add relays and other protective equipment.
6. Install phase reactors and string buss in main switchyard to limit fault current.
7. Add breaker in bay # 7 (7WE) for new Indiantown # 2 transmission line. Tap existing 69kV auto-transformer off east 230kV operating bus.
8. Add breaker in Bay # 3 (3WS) at Indiantown Substation for Bridge line.
9. Create new bay 4. Add breakers 4WM, 4WS for Indiantown-Martin #2 line at Indiantown Substation.
10. Create new bay # 1 at Bridge Substation with breakers 1WW and 1WM. Add breakers 2WW and 2WE to convert station configuration from ring buss.
11. Construct one string bus to connect the collector and main switchyard.

II. Transmission:

1. Construct 230kV Martin-Indiantown # 2 transmission line.
2. Construct 230kV Indiantown – Bridge # 2 transmission line.
3. Various OHGW replacements due to increased fault current.
4. Upgrade the Ranch-Homeland 230kV transmission line to 1330 Amps.

III.G. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various technologies.

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970's in demonstrating the first residential solar photovoltiac (PV) system east of the Mississippi. This PV installation at FESC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities on both a daily and annual basis in Florida. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-Kilowatt (KW) system was placed into operation in 1984. (After the testing of this PV installation was completed, the system was removed in 1990 to make room for substation expansion.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed on the following page).

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first and only utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was not cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980's, FPL introduced another renewable energy program. FPL's Passive Home Program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for 6 passive homes with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test may be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

More recently, FPL has analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach does not require all of its customers to bear PV's high cost, but allows customers who are interested in facilitating the use of renewable energy the means to do so. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund that FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid. Thus, when sunlight is available, the PV-generated electricity displaces an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach, which has been termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's initial efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL initiated the effort in 1998 and received approximately $89,000 in contributions (that significantly exceeded the goal of $70,000). FPL has purchased the PV modules and installed them at FPL's Martin Plant site.

As previously discussed, FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was the Green Energy Project which is a second, different attempt to implement the basic Green Pricing approach. Under this project FPL would purchase electric energy generated from new renewable sources. The project would offer to supply to FPL's electrical grid the equivalent of all, or part of, a customer's monthly kWh usage with electricity generated from these new renewable resources. Participants would be residential (and possibly commercial) customers who would pay higher ("green" rates) for electricity provided from these renewable sources. FPL issued a Request for Proposals (RFP) in 2001 to solicit proposals to potentially supply energy only (MWH) from new renewable sources.

The second effort initiated in 2000 is FPL's Photovoltaic Research, Development, and Education Project. This demonstration project's objectives are to increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks (as well as the total annual energy capabilities of roof tile PV systems), and assess the homeowner's financial benefits and costs of PV roof tile systems.

Finally, FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy and as-available energy have been purchased by FPL from these developers. (Please refer to Tables I.B.1 and I.B.2).

III.H FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980's, FPL relied primarily on a combination of oil, natural gas, and nuclear energy to generate electricity. In the early 1980's FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix, through FPL's partial ownership and additional purchases from, the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit # 4 in 1989. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at the St. Johns River Power Park.

The trend in recent years has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective combined cycle generating units. Although this planning document reflects a continuation of this trend, FPL's proposed capacity additions for the years 2008 through 2012 present a plan that is subject to change. FPL's future resource planning work will increasingly focus on identifying and evaluating alternatives that would maintain/enhance FPL's long-term fuel diversity. These fuel diversity-enhancing alternatives may include: extending and/or expanding existing solid/fuel-based power purchases, the construction of, and the purchase of power from, new solid fuel-based (coal and petroleum coke) facilities; obtaining access to diversified sources of natural gas such as from suppliers of natural gas from international production areas; and preserving FPL's ability to utilize fuel oil at is existing units. The feasibility and cost-effectiveness of these, and possibly other, alternatives will be analyzed in future planning cycles.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2012 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2.

2. Fuel Price Forecasts

FPL's long-term oil price forecast assumes that worldwide demand for petroleum products will grow moderately throughout the planning horizon. Non-OPEC crude oil supply is projected to increase as new and improved drilling technology and seismic information will reduce the cost of producing crude oil and increase both recoveries from existing fields and new discoveries. However, the rate of increase in non-OPEC supply is projected to be slower than that of petroleum demand, resulting in an increase in OPEC's market share throughout the planning horizon. As OPEC gains market share, prices for petroleum products are projected to increase.

FPL's natural gas price forecast assumes that domestic demand for natural gas will grow throughout the planning horizon, primarily due to increased requirements for electric generation. Domestic natural gas production will increase as new and improved drilling technology and seismic information will reduce the cost of finding, developing, and producing natural gas fields. The rate of increase in domestic natural gas production is assumed to be slower than that of demand nationally, with the balance being supplied by increased Canadian and liquefied natural gas (LNG) imports. As demand for natural gas in Florida grows, it is anticipated that the Florida Gas Transmission (FGT) pipeline system will be augmented/expanded. This anticipated expansion of FGT's pipeline, combined with the new Gulfstream pipeline and potential sources of non-domestic/international natural gas (such as off-shore suppliers), should result in sufficient gas for FPL's continued needs.

FPL's coal price forecast assumes an ample supply of domestic coal, and the availability of imported coal, to meet a slow, but steady increase in domestic demand in the electric generation sector over the planning horizon. The coal price forecast for FPL's existing coal plant at St. Johns River Power Park (SJRPP) and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts unit expiration, along with the purchase of spot coal, to meet generation requirements. FPL's petroleum coke price forecast assumes that the petroleum industry will continue to cokers in the U.S., as well as in the Caribbean Basin in order to maximize refinery production of light products. This trend will continue to result in sufficient availability of petroleum coke, at delivered prices significantly below delivered coal prices. To support a slow, but steady growth in the use of petroleum coke in the U.S. electric utility industry.

(4)	Line Length:	10.0 miles
(5)	Voltage:	230 kV
(6)	Anticipated Construction Timing:	Start date: 10/1/03 End date: 12/31/04
(7)	Anticipated Capital Investment: (Trans. and Sub.)	$8,900,000
(8)	Substations:	Indiantown and Bridge
(9)	Participation with Other Utilities:	None

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in our service area is continuing, which heightens competition for air, land, and water resources that are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among utilities for our commitment to the environment. Our environmental leadership has been heralded by many outside organizations. For example, FPL was recently ranked first out of 28 major electric utilities surveyed in an environmental assessment conducted by Innovest, an independent advisory group. FPL was also awarded Edison Electric Institute's National Land Management Award for our stewardship of 25,000 acres surrounding our Turkey Point Plant. In addition, FPL won the Council for Sustainable Florida's award for our sea turtle conservation and education programs at our St. Lucie Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. We also received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" for our emission-reducing "repowering" projects at our Fort Myers and Sanford Plants. In addition, FPL has been recognized by numerous federal and state agencies for our innovative endangered species programs which include such species as manatees, crocodiles, and sea turtles.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define the Company's position. This statement reflects how FPL incorporates environmental values into all aspects of the Company's activities and serves as a framework for new environmental initiatives throughout the Company. The FPL environmental statement further establishes a long-term direction of environmental initiatives throughout the Company. FPL's Environmental Statement is:

> It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:
>
> - Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
> - Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
> - Encourage the wise use of energy to minimize the impact on the environment.
> - Communicate effectively on environmental issues.
> - Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident/emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with Company policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to: facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and Company policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2002 environmental outreach activities are noted in Table IV.E.1.

Activity	***# of Participants***
Visitors to Energy Encounter	19,000
Visitors to Manatee Park	150,000
Number of "visits" to FPL's Environmental Website	80,000
Number of pieces of Environmental literature distributed	>100,000

(All numbers are approximations.)

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified preferred and potential sites for future generation additions. These preferred and potential sites are discussed in separate sections below.

IV.F.1 Preferred Sites

FPL identifies four preferred sites in this Site Plan: the existing Fort Myers plant site, the existing Sanford plant site, the existing Martin plant site, and the existing Manatee plant site. These four sites are the locations for capacity additions that FPL is committed to make during the 2003-2005 period.

The four preferred sites are discussed below.

Preferred Site # 1: Fort Myers Plant, Lee County

The site is located on the 460-acre Fort Myers property. A repowering project has recently been completed at this facility. Six combustion turbines (CT's) were added that, along with heat recovery steam generating (HRSG) units and the existing steam turbines, comprise the main portion of the repowered facility. These units were completed and began commercial operation on natural gas in May 2002. Approximately 929 MW of incremental Summer capacity and 1,073 MW of incremental Winter capacity was added through the repowering. An existing bank of 12 simple cycle combustion turbine peaking units is also located at the site.

Two additional peaking simple cycle combustion turbines are under construction and are expected to begin commercial service in mid-2003. These peaking combustion turbines have dual fuel capability and are able to operate on either natural gas or distillate oil. These combustion turbines will add an additional 298 MW of Summer capability and 366 MW of Winter capability to the site.

The output capability of the existing bank of 12 CT's and the repowered unit at the site will be unaffected by the addition of the two new CT's.

The site has direct access to a four-lane highway, State Road (SR) 80, and barge access is available. The nearest town is Tice which is approximately 8 miles west of the site. The Fort Myers site has been listed as a potential or preferred site in previous FPL Site Plans.

a and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout Map

A USGS map of the Fort Myers plant site, plus a map of the general layout of the proposed generating facilities at the site, is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter. It is pertinent to note that several designations on the current South Florida Water Management District Florida Land Use, Cover, and Forms

Classification System (FLUCCS) appear to be in error or to require some clarification. For example, the freshwater marsh identified toward the western boundary of the site is actually FPL's 50-acre evaporation/percolation pond. Similarly, while there are scattered mangroves along the shore, the "Central Mangrove" area shown is not mangrove but is the FPL switchyard for that site. The "Improved Pasture" shown towards the east of the site is currently the location of a tree nursery.

d. <u>Existing Land Uses of Site and Adjacent Areas</u>

The land on the site is primarily dedicated to industrial use with surrounding grassy and landscaped areas. There is the previously mentioned 50-acre evaporation/percolation pond on the site. Much of the site has been recently used for direct construction activities.

FPL has recently donated an 18-acre island, located north of the plant in the Caloosahatchee River, to the United States Fish & Wildlife Service (USFWS) for the purpose of wildlife conservation. This island has been owned by FPL since the 1950's, but has never been developed. The USFWS has incorporated the island into the Caloosahatchee National Wildlife Refuge.

Lee County operates Manatee Park, (approximately 5 acres) with a manatee viewing area on FPL property to the east side of the discharge canal where it adjoins the Orange River south of SR 80. This manatee viewing area provides public viewing and education about the species.

The adjacent land uses are light commercial and retail to the east of the property and some residential areas located toward the west. Mixed scrub with some hardwoods and wetlands, plus agriculture land, can be found to the east and further to the south. The Caloosahatchee National Wildlife Refuge is located across the Caloosahatchee River, northwest of the power plant.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

The site is adjacent to the south bank of the Caloosahatchee River near the confluence of the Orange River and the Caloosahatchee. Much of the site is no longer in its original natural condition. However, a scattering of mangroves can be found along the river shoreline. Some mixed scrub with some hardwoods and wetlands can be found to the east and further to the south. Other than the occasional congregation of manatees noted below, FPL is not aware of any significant environmental features on the site or in the vicinity.

2. Listed Species

The construction and operation of the new CT's at the site is not expected to affect any rare, endangered, or threatened species. The only known listed species associated with the site are the West Indian Manatees (Trichechus manatees: Federal - and State - listed as endangered) which are attracted to the warmed waters in the vicinity of the site discharge and can be found congregating in the area during cool weather.

The Florida Natural Areas Inventory (FNAI) reports the presence of the Eastern Indigo Snake (Drymarchons corais couperi: Federal - and State - listed as Threatened) and Tricolored Heron (Egretta triccolor: State - listed as a Species of Special Concern) within a two-mile radius of the site.

3. Natural Resources of Regional Significance Status

No Natural Resource of Regional Significance is identified on the plant site in the Southwest Florida Regional Strategic Policy Plan.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option currently being pursued for the Fort Myers site is the addition of two stand-alone CT's. This new generation equipment will be installed on the existing facility property and will make effective use of existing transmission facilities and infrastructure although some substation and transmission line upgrades were required.

Mitigation options that have been incorporated include the use of combustion technology that is inherently low in air pollutant emissions.

g. Local Government Future Land Use Designations

The Local Government Future Land Use Plan designates the major portion of the site as Public Facilities and a small area as Resource Protection. Since there are no significant environmental resources on the site, and the "Resource Protection" designated area appears to be the location of a current tree nursery, FPL believes that this designation is in error.

h. Site Selection Criteria and Process

The Fort Myers plant has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered ideally suitable for future expansion.

i. Water Resources

The available surface water source is the Caloosahatchee River and the available groundwater source is the sandstone aquifer.

j. Geological Features of Site and Adjacent Areas

The geology underlying the Fort Myers Plant consists of Quaternary Holocene and Pleistocene undifferentiated materials. The upper part of these undifferentiated materials consists of fine-to-medium grained quartz sand with varying percentages of shell and clay. Hardpan frequently occurs at the base of the quartz sands. The lower section consists of shell beds with interbedded limestone. Underlying the undifferentiated materials are the Pliocene Tamiami formations, the Miocene Hawthorn formation, Oligocene Suwanee Limestone, the Eocene Crystal River and Williston formations, the Avon Park Limestone, and the Lake City Limestone.

Several stratigraphic units can be differentiated based upon shallow borings drilled on the plant property. Sand with some heterogeneous fill material related to past site construction activity covers most of the surface. It is underlain by layers of clayey sand and clay to a depth of approximately 23 feet. These units mantle a thicker clay unit with numerous shell fragments that occurs from 15 feet to about 55 feet below the surface. A silty sand with a trace of clay was encountered at 55 feet near the termination depth of one deep boring on the site.

The water table at the site occurs at levels from just under the surface to about 5 feet below grade. Locally, the surficial aquifer and surface water will generally flow toward the Caloosahatchee River. However, at the site, the intake and discharge canal will affect groundwater near the power block area. A drainage canal that borders the plant property on the west will affect groundwater flow along the western portion of the waste treatment area.

k. Projected Water Quantities For Various Uses

Facility water uses may include irrigation, potable use, etc. The total volume of these uses is estimated to be about 65 gallons per minute (gpm).

l. Water Supply Source By Type

For industrial processing, FPL anticipates that groundwater will be available. The new CT's will be air-cooled.

m. Water Conservation Strategies Under Consideration

A plan to treat and recycle equipment wash water, boiler blowdown, and equipment area runoff for use as service water would reduce ground water consumption.

n. Water Discharges and Pollution Control

Heated water discharge for the plant site as a whole will be dissipated using both the existing once-through cooling water system and a multi-cell-helper-cooling tower which will be used during the warmer months. Storm water runoff will be collected and used to recharge the surficial aquifer via a storm water management system. Design elements will be included to capture suspended sediments. Various facility permits mandate various sampling and testing activities which will provide an indication of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasures (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The combustion turbine-based repowering project, plus the addition of the two new CT's, required a natural gas pipeline to be installed. Florida Gas Transmission completed the permitting process and installed and operates the pipeline that serves the Fort Myers Plant. Virtually no solid waste is associated with natural gas firing.

p. Air Emissions and Control Systems

The natural gas-fired facilities at the plant site generally have air pollutant emissions that are substantially lower than emissions from the former oil-fired boilers. While several technologies are available for nitrogen oxide (NO_x) emissions control, FPL is using a dry-low-NO_x combustion turbine design. In these devices, combustion is staged in order to reduce the formation of combustion-derived oxides of nitrogen. FPL has committed to NO_x emission limits for this facility that will be among the lowest in the state. Sulfur dioxide and particulate emissions are intrinsically low due to the lack of sulfur and solids in natural gas fuel. Carbon monoxide and volatile organic compound emissions can each be controlled via the use of efficient combustion rather than through the use of add-on control devices. CT facilities have been permitted at several locations throughout the state of Florida including near Class I areas. Dry-low-NO_x combustor systems have been repeatedly demonstrated to be the Best Available Control Technology (BACT) for the control of NO_x emissions for this technology pursuant to the requirements of the Clean Air Act.

q. **Noise Emissions and Control Systems**

Lee County has a noise ordinance that limits noise at receiving property lines of residential, public space, agricultural, or institutional to 66 decibels in the daytime and 55 decibels at night. FPL will undertake studies to assure that noise level associated with the new CT's comply with the Lee County noise standard.

r. **Status of Applications**

FPL acquired all permits needed to commence construction. Modifications to operating permits were requested in 2002 and will continue to be pursued as necessary through 2003.

Preferred Site # 2: Sanford Plant, Volusia County

The site is located on the 1,718-acre FPL Sanford property just west of Lake Monroe on the north bank of St. Johns River in Volusia County. Current facilities on the site include one steam electric generating unit with a nominal rating of 138 MW and a recently repowered natural gas-fired unit with a nominal rating of 910 MW. One other existing unit, Unit # 4, has been shut down and is in the process of being repowered using combined cycle technology. The site is within the city limits of Debary, and the community of Debary is located approximately 2 miles to the northwest. The town of Deland is approximately 4 miles west of the site. The site has direct access to a four-lane highway, State Road (SR) 17-92, and barge access is available. The Sanford site has been listed as a potential or preferred site in previous FPL Site Plans.

As mentioned above, FPL is in the process of adding new capacity at the Sanford site by replacing one existing oil-and gas-fired unit (i.e., existing Unit # 4) with advanced natural gas fired combustion turbines (CT's) and heat recovery steam generators (HRSG's). This type of steam generation replacement is commonly called repowering.

This repowering will enable FPL to produce significantly more electrical output with nearly the same environmental impact. The repowering of Unit # 4 will produce approximately 567 additional MW during Summer conditions, and approximately 652 additional MW of generation during Winter conditions, beyond the current capabilities of this unit. The existing 138 MW Unit # 3 and the recently repowered Unit # 5 will be unaffected by the repowering of Unit # 4.

a. and b. <u>U.S. Geological Survey (USGS) Map and Proposed Facilities Layout Map</u>

A USGS map of the Sanford plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. <u>Map of Site and Adjacent Areas</u>

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. <u>Existing Land Uses of Site and Adjacent Areas</u>

A large part of the property is covered by the 1,100-acre closed cycle cooling pond that occupies almost the entire northern portion of the site. The remainder of the site is primarily rangeland and the power plant facilities.

The surrounding land use is largely crop land and pasture. To the east of the plant there is a small residential area and some commercial/industrial land use. There are some residential areas mixed in with the agricultural areas located between the site and the St. Johns River to the west. To the south is the St. Johns River. Residential homes and commercial/industrial businesses are located along the south side of the river.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

Small, scattered wooded areas can be found on the site. There are two small areas of wetland marsh on the site and a few acres of wetland forest along the riverbank. There are some wooded areas on the site, primarily upland coniferous forest. Forested and non-forested wetlands can be found to the west, adjacent to the river. River and wetland areas towards the northwest are designated as part of the Wekiwa River Aquatic Preserve and Wekiwa River State Preserve.

2. Listed Species

One inactive bald eagle (Haliaeetus leucocephalus: Federal - and State - listed as Threatened) nest has been found on the site. Bald eagles have also nested in the Lake Monroe area. There are a number of other eagles nests in the vicinity of the site, primarily the St. Johns River. The Florida Natural Areas Inventory (FNAI) reports several Scrub Jay populations (Aphelocoma coerulescens: Federal - and State - listed as Threatened) located in scrub vegetation to the northwest of the site. West Indian Manatees (Trichechus manatus: Federal - and State - listed as Endangered) have also been found in this area.

3. Natural Resources of Regional Significance Status

The Wekiwa River Aquatic Preserve extends along the St. John's River in the vicinity of the plant.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option for the Sanford Site is the repowering of one existing oil - and gas - fired boiler with natural gas fired combustion turbines (CT's) and heat recovery steam generators (HRSG's). Steam produced in the new HRSG's is directed to the existing steam turbine. Natural gas - fired facilities represent one of the cleanest, most efficient technologies currently available for capacity additions to FPL's system.

g. Local Governmental Future Land Use Designations

The site is designated as "Industrial Utilities" in the Local Government land use plan. The city is currently updating its Land Use Plan. It is expected that the name, but not the expected use designation, may change. Land use designation of the surrounding area is primarily Agricultural. There is an area of "Public Institution" around Lake Monroe to the southeast and a small area of "Mixed Use" to the west along Barwick Road.

h. Site Selection Criteria and Process

The Sanford plant has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All are considered permittable.

i. Water Resources

For surface water supply, the available water resource is the St. John's River and/or the on-site cooling pond, which is periodically refilled from the St. John's River. For ground water supply, the available resources are the shallow aquifer or the Floridan Aquifer.

j. Geological Features of Site and Adjacent Areas

The near-surface geology of Volusia County within the St. John's River Valley, like that of most of north central Florida, is represented by late Tertiary and Quaternary geological units. Soils in the vicinity of the plant include unconsolidated Pleistocene to Recent sands, with intervening beds of shells and clay. These deposits from the reservoir for the surficial aquifer in the county. One of the two major structural features in the area is the Peninsula Arch that forms the backbone of the Florida Platform. The arch trends south-southeast and extends from southeast Georgia through Florida into the Great Bahamas. The geological material can be divided into an upper sequence of unconsolidated or poorly consolidated clastic sediments and a lower sequence of limestone rocks. These lower formations are part of the principle hydrologic unit referred to as the Floridan Aquifer. This aquifer, the top of which generally occurs through the region at or below 100 feet, is the major source of potable groundwater in Volusia County. Two faults, one trending north-to-south, the other trending east-to-west, intersect a number of miles north of the site. Downward displacement of the fault is hypothesized as being approximately 60 to 100 feet. The upper clastic region ranges in age from Miocene to Recent and is mostly sand but also contains discontinuous and interfingering lenses and beds of clay and silt.

k. Projected Water Quantities for Various Uses

FPL has estimated that 150 gallons per minute (gpm) is required for industrial processing purposes (boiler makeup, service water, etc.). Note that Unit # 4 currently takes its cooling water directly from an on-site FPL cooling pond and will continue to do so after repowering is completed. The cooling water needs for both of the repowered facilities (i.e., Unit # 4 and Unit # 5) will represent an increase over previous cooling water needs due primarily to the increased heat loading to the cooling pond that results from operating the larger repowered units more than they have been operated in the past and corresponding evaporative losses. Therefore, greater quantities of water will be used. Existing Unit # 3 will continue to use water from the St. John's River in a once-through cooling mode.

FPL evaluated alternative sources of water to meet the expected needs of the site. The existing off-site wells and the existing once - through cooling water system and cooling pond will continue to be used after the repowering project is completed, albeit the use of groundwater will decrease significantly from past usage.

l. Water Supply Sources by Type

The available surface water supply source is the St. John's River. The Floridan Aquifer is an available groundwater source for service water and boiler water.

m. Water Conservation Strategies Under Consideration

In 2000 FPL obtained a revised Consumptive Use permit from the St. John's Water Management District. This permit reduced the quantity of water that FPL has historically been permitted to withdraw from the ground in favor of additional use of surface water.

n. Water Discharges and Pollution Control

Heated water discharges will be dissipated using the existing once - through cooling water system of the existing cooling pond for repowered Unit # 4. Non-point source discharges are collected and reused. Treating and recycling equipment wash water, boiler blow-down, and equipment area runoff helps to minimize industrial discharges. Storm water runoff is collected and used to recharge the surficial aquifer via a stormwater management system. Design elements have been included to capture suspended sediments. Various facility permits mandate sampling and testing activities which provide indications of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The repowered facilities at the Sanford site required a larger natural gas pipeline to be installed. FPL contracted with Florida Gas Transmission Company (FGT) to permit, install, and operate this facility which is now fully operational. Virtually no waste is associated with natural gas firing.

p. Air Emissions and Control Systems

A natural gas-fired facility generally has air pollutant emissions that are substantially lower than emissions from the prior oil-fired boilers. While several technologies are available for nitrogen oxide (NO_x) emissions control, the chosen technology for the Sanford site is a dry low NO_x combustion turbine design type. In these types of devices, combustion is staged in order to reduce the formation of combustion-derived oxides of nitrogen. Sulfur dioxide and particulate emissions are intrinsically low due to the lack of sulfur and solids in natural gas fuel. Carbon monoxide and volatile organic compound emissions can each be controlled via the use of efficient combustion rather than through the use of add-on control devices. CC and CT facilities have been permitted at several locations throughout the state of Florida. Dry-low-NOx combustor systems have been repeatedly demonstrated to be the Best Available Control Technology (BACT) for the control of NO_x emissions for this technology pursuant to the requirements of the Clean Air Act.

q. Noise Emissions and Control Systems

Noise emissions from the project are not significantly different from current levels at the plant prior to repowering. FPL installed appropriate sound attenuation devices including insulation on high energy piping systems in order to ensure that sound levels do not exceed allowable levels. Similar natural gas-fired facilities (the Lauderdale plant in Broward County, the Fort Myers plant in Lee County, and the Martin plant in Martin County) have been constructed and operated without exceeding allowable noise levels.

r. Status of Applications

FPL acquired all permits needed to commence construction. Modifications to operating permits were requested in 2002 and will continue to be pursued as necessary through 2003.

Preferred Site # 3: Manatee Plant, Manatee County

The site is located in unincorporated north central Manatee County approximately 2.5 miles south of the Hillsborough-Manatee County line. It is 5 miles east of Parrish, Florida and is approximately 5 miles east of U.S. Highway 301 and 9.5 miles east of Interstate 75 (I-75). State Road (SR) 62 is about 0.5 miles south of the site. Saffold Road marks the eastern boundary of the site.

FPL's Manatee Plant occupies a portion of the approximately 9,500 acre Manatee Site which is owned wholly by FPL. The site includes a 4,000-acre cooling pond including the dike area. The existing approximately 1,620 MW (Summer) of generating capacity is made up of two steam units (Units # 1 and # 2) which have been in service since 1976 (Unit # 1) and 1977 (Unit # 2). These units burn both fuel oil (residual) with a maximum sulfur content of 1 percent and natural gas. Natural gas may be fired singly or in combination with fuel oil. A recent agreement between FPL and Gulfstream Natural Gas Systems (Gulfstream) will provide two natural gas sources for these units.

Pending final approval by the Governor and Cabinet, additional generating capacity will be added to the site in 2005 to meet projected FPL system capacity needs. Four new combustion turbines (CT's), four new heat recovery steam generators (HRSG's), and a new steam turbine generator are scheduled for in - service operation beginning in June, 2005. The four new CT's, HRSG's and steam turbine will ultimately be operating in combined cycle (CC) configuration. This new CC unit will add 1,107 MW (Summer) and 1,201 MW (Winter) capability to the site. This new CC Unit will be designated as "Manatee Unit # 3".

Unit # 3 will be located west of the existing generating Units # 1 and # 2. The location of the new combined cycle Unit # 3 at the Manatee Plant site and the selection of the highly efficient combined cycle technology (firing clean natural gas) will maximize the beneficial use of the site while minimizing environmental and land use impacts otherwise associated with the development of a new generating plant of this capacity. The Manatee site has been previously listed as a preferred or potential site in previous FPL Site Plans.

a. and b. Map of the Manatee Plant Site and Land Use

A map indicating the Manatee plant site showing the general layout of the facilities and a map indicating the land use of the site are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 4,000 acre cooling pond. Manatee Units # 1 and # 2 will not be affected by the addition of Unit # 3. The area for Unit # 3 is expected to comprise approximately 73 acres. The site and surrounding land uses are almost exclusively agriculture with the exception of the Willow Shores residential area located northwest of the Manatee Plant site. Individual homes are located in the larger of two out parcels within the Manatee Plant site along SR 62 at the northeast corner of the site. The vast majority of the Manatee Plant site has been redesignated from Agricultural/Rural to Major Public/Semi Public (1) (P/SP) land use category by the Manatee County Commission on November 19, 2002 with the approval of Ordinance 02-13. Electric generating plants are specifically allowed in the P/SP category in accordance with the Manatee County Local Government Comprehensive Plan and Land Development Regulation Act, Chapter 163, Part II, Florida Statutes (FS).

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

There are no incorporated areas within 5 miles of the Manatee Plant site. Unincorporated communities in the area include Willow, located about 2 miles north of the Manatee Plant; Parrish, located about 5 miles southwest of the plant; and, in Hillsborough County, Sundance, located 3 miles northwest of the plant; Sun City Center, located 7 miles north of the plant; and Wimauma, located 8 miles northeast of the plant.

The Manatee Plant site includes areas of improved pasture with forested land southeast of the project area. This forested area is comprised of flat woods and oak habitat. The western side of the Manatee Plant site is currently used for row crops (tomato farm). There are also wetlands to the southeast containing wet pine flat woods mixed with dry pine flat woods. There will not be any disturbance of existing wetlands associated with this project.

2. Listed Species

Construction and operation of the new Unit # 3 at the site is not expected to affect any rare, endangered, or threatened species. The majority of the site is cleared, grassed, and periodically mowed. The project area has been significantly altered by the construction and operation of the existing plant facilities, and, as a result, wildlife utilization of this area is expected to be minimal. Common wading birds utilizing the plant site outside of the project area include the great blue heron, little blue heron, great egret, snowy egret, and the white ibis. Typical mammals found in the habitats surrounding the project area are common bobcat, raccoon, deer, ferel hog, opossum, armadillo, skunk and gray squirrel. Avian species observed in the vicinity of the project include bald eagles, a variety of songbirds, red-shouldered hawks, and marsh hawks.

3. Natural Resources of Regional Significance Status

There are no county, State or Federally designated areas located within one mile of the plant site. The construction and operation of Manatee Unit # 3 is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands that are associated with the Little Manatee River within a 5-mile radius of the project site. These lands include: Little Manatee River State Recreation Area, Little Manatee River State Canoe Trail, Florida Gulf Coast Railroad Museum, Cockroach Bay Aquatic Preserve, Critical

Manatee Habitat, South Hillsborough Wildlife Corridor, Hillsborough County ELAPP Parcels, and SOR-Little Manatee River.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option, Manatee Unit # 3, is the addition of four new combustion turbines and HRSG's and one new steam turbine generator in combined cycle mode in a 4x1 configuration. Manatee Unit # 3 is scheduled to begin operation in mid – 2005. Natural gas, delivered via pipeline, will be the sole fuel for this unit.

Mitigation options being planned for Manatee Unit # 3 include the capture and reuse of plant process water and rainwater. In addition, other mitigating options include the use of combustion technology that is very efficient and low in air pollutant emissions, combined with pollution control technology (dry-low NO_x burners and selected catalytic reduction equipment).

g. Local Government Future Land Use Designations

As mentioned above, the Local Government Future Land Use Plan is consistent with the existing Designated uses of the Manatee Plant Site as major portions of the site are designated as Major Public/Semi Public (1) – P/PS/. Electric generating plants are specifically allowed in this land use category.

h. Site Selection Criteria and Process

The Manatee site has been selected as a preferred site due to consideration of various factors including system load and economics. Also, the at – the – time projected availability of a natural gas pipeline that will be available to Unit # 3 (as well as Units # 1 and # 2) in the near future was also a major factor in the selection of the Manatee site for the new 4x1 CC unit. Environmental issues were not a deciding factor since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered permittable.

i. Water Resources

The available surface water source is the Little Manatee River which supplies makeup water for the 4,000-acre cooling pond. Plant process and service water requirements are currently supplied by the cooling pond. There are three wells in the Floridan Aquifer that are reserved for standby purposes.

j. Geological Features of Site and Adjacent Areas

Manatee County has three physiographic provinces: the Gulf Coast Lowlands, the DeSoto Plains, and the Polk Upland. The Manatee Plant is situated on the boundary of the DeSoto Plains and the Gulf Coast Lowland provinces. The geology underlying the Manatee Plant consists of unconsolidated sediments comprised of sand, clay silt, marl shell, limestone, and phosphorite (terrace deposits) from the Pleistocene age to recent. Undifferentiated deposits comprised of sand and clay are generally described to be less than 25 feet thick. Underlying the differentiated materials are the Miocene Hawthorn Formation, the Tampa Member, the Suwanee Limestone of the Oligocene age, the Ocala Limestone of the Eocene Age, the Avon Park Formation, the Oldsmar Formation of the Eocene age, and the Cedar Key Formation of the Paleocene age.

The major hydrogeologic units that exist in the vicinity of the site include, in descending order: the surficial aquifer system, the intermediate aquifer system, and the Upper Floridian aquifer. The surficial aquifer system is generally unconfined in Manatee County and consists of Quarternary deposits of predominately marine and nonmarine quartz sand, clayey sand, shell, shelly marl, phosphorite, and occasional stringersmarl and limestone. In the vicinity of the site the surficial sediments are approximately 25 feet thick.

k. Projected Water Quantities for Various Uses

The estimated additional quantity of water for industrial processing is estimated to be 150 gpm (gallons per minute) plant process and service water.

FPL operates on-site water treatment systems for each of these uses. Water quantities for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l. Water Supply Sources by Type

Manatee Unit # 3 will utilize the existing on-site cooling pond as its source of cooling water. The cooling pond operates as a “closed cycle” system; any makeup water is provided from the Little Manatee River to replace net evaporation and seepage losses from the pond. These makeup needs are within the existing agreement between FPL and the Southwest Florida Water Management District (SWFWMD). There are three wells currently on reserve (stand-by) that are in the Floridan Aquifer. FPL is currently evaluating alternative water sources for use at the Manatee Plant site.

m. Water Conservation Strategies Under Consideration

Available water including non-contact storm water, treated industrial wastewater, treated sanitary wastewater, and recovered service water are captured and returned to the cooling pond. Storm water from the equipment areas is also treated and returned to the cooling pond.

n. Water Discharges and Pollution Control

The Manatee Plant utilizes a Best Management Practices (BMP) plan, Spill Prevention, Control, and Countermeasure (SPCC) plan to assist in the control of inadvertent release of pollutants. Storm water runoff will be collected and routed to detention ponds. Construction activities will be managed so that equipment maintenance and fueling are performed in designated areas so that, in the event of a spill or release of any contaminant, impacts to any surface water or the cooling pond are minimized.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by fuel delivery services and facilities for residual, low sulfur (1 percent) fuel oil and, most recently, natural gas as an alternate fuel for existing Units # 1 and # 2. The Unit # 3 addition will be solely fueled by natural gas that could be supplied by either Gulfstream or FGT as previously discussed.

p. **Air Emissions and Control Systems**

The addition of natural gas as a permitted fuel for existing Units # 1 and # 2 is expected to lower overall emissions during periods when natural gas, instead of fuel oil, is used. In addition, a NO_x reduction technology, reburn, has been approved for installation on Units # 1 and # 2 within the next several years.

The use of clean fuels and combustion controls will minimize air emissions from Unit # 3 and ensure compliance with applicable emission limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of carbon monoxide and volatile organic compounds. NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Manatee Unit # 3 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. **Noise Emissions and Control Systems**

Noise emissions from the project are not anticipated to be significantly different from the current levels at the existing plant. Similar natural gas-fired facilities in Broward and Martin Counties have been constructed and operated without exceeding allowable noise levels.

r. **Status of Applications**

FPL filed the Site Certification Application (SCA) for the Manatee Plant Unit # 3 with the Florida Department of Environmental Protection (FDEP) on February 20, 2002 and received a positive recommendation from the Administrative Law Judge (ALJ) for the project on February 19, 2003.

Preferred Site # 4: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District (SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad. The Martin site was identified in 1987 as a preferred location for development of coal gasification/combined cycle electric generation facilities and subsequent FPL Site Plans have continued to identify this site as a preferred site.

The existing 2,850 MW (Summer) of generating capacity at FPL's Martin site occupies a portion of the approximately 11,300 acres that are wholly owned by FPL. The generating capacity is made up of two steam units (Units # 1 and # 2), plus two combined cycle units (Units # 3 and # 4), and two combustion turbine units (Units # 8a and # 8b). The site includes a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

Additional generating capacity was added to the site in 2001 in the form of two combustion turbines (CT's) that operate in simple cycle mode using natural gas. Pending final project approval by the Governor and Cabinet, these two CT's will be converted into a four-on-one (4X1) combined cycle (CC) unit with the addition of two new CTs, four new Heat Recovery Steam Generators (HRSGs), and a new steam turbine generator. The resulting CC unit will be known as Martin Unit # 8. It is estimated to be in service in mid-2005 adding approximately 800 MW of capacity.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the Martin plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres. To the east of the power plant there is an area of mixed pine flat wood with a scattering of small wetlands. To the north of the cooling pond there is a 1,200-acre area which has been set aside as a mitigation area. There is a peninsula of wetland forest on the West Side of the reservoir, that is named the Barley Barber Swamp. The Barley Barber Swap encompasses 400 acres and is preserved as a natural area. There is also a 10-kilowatt (kW) photovoltaic energy facility at the south end of this site.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

As noted above, the Barley Barber Swamp is located on the site. There is also a 1,200-acre mitigation area in the northern area of the site where wetlands and uplands have been restored. Along the south and west sides of the cooling pond is an area where the vegetation has been maintained in its natural state in order to serve as a wildlife corridor. There are pine flat woods and small-scattered wetlands to the east of the plant.

2. Listed Species

Construction and operation of a new unit at the site is not expected to affect any rare, endangered, or threatened species. There are two active Bald Eagle (*Haliaeetus leucocephalus*: Federal - and State - listed as Threatened) nests that have been on the site for many years. The Florida Natural Areas Inventory (FNAI) database notes a record of Eastern Indigo Snakes (*Drymachon coralis coupert*, which are Federal - and State - listed as threatened) in the Barley Barber Swamp. A number of other Bald Eagle nests and sightings of Eastern Indigo Snakes are reported by the FNAI database within a two-mile radius of the site. Infrequent sightings of Florida Panther have been made in the vicinity of the site area.

3. **Natural Resources of Regional Significance Status**

The Treasure Coast Regional Planning Council lists the "FPL Preserve", including the Barley Barber Swamp, as a Significant Regional Facility. Natural communities such as uplands and wetlands are also generically listed as Resources of Regional Significance.

4. **Other Significant Features**

FPL is not aware of any other significant features of the site.

f. **Design Features and Mitigation Options**

The design option is to add two new CT's and four new HRSG's and a new steam turbine that, together with the two existing CT's, will comprise Martin Unit # 8. This unit is scheduled to be in-service in mid-2005. Natural gas delivered via pipeline is the primary fuel type for this unit (with light oil serving as a backup fuel). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation options being considered include the capture and reuse of plant process water and rainwater, plus the use of cooling towers. The facility already encompasses several preserved areas where wildlife is abundant.

g. **Local Government Future Land Use Designations**

Local government future land use designation for the site is "Public Utilities". Designations for the surrounding area are primarily "Agricultural". There are also limited areas of "Agricultural Ranchette", "Industrial", and a small "Commercial" area designation. To the southeast of the property, fronting on the St. Lucie Canal, is an area designated for "Public Conservation".

h. Site Selection Criteria Process

The Martin plant has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since none of the existing preferred and potential sites exhibit significant environmental sensitivity or other environmental issues. All of these sites are considered permittable.

i. Water Resources

Surface water resources currently used at the Martin facility include the cooling pond which takes its water from the St. Lucie canal. The available ground water resource is the surficial aquifer system which is used as a source of potable water and for service water for Units # 1 and # 2. Both of these sources are available for use with the site expansion.

j. Geological Features of Site and Adjacent Areas

FPL's Martin site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine bin origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The deepest formation in Martin County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Lake City formation. The published information on the sediments comprising the formations below the Avon Park Limestone in western Martin County is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach Counties.

k. Projected Water Quantities for Various Uses

The estimated additional quantity of water required for industrial processing is 130 gallons per minute (gpm) for uses such as boiler water and service water.

FPL operates on-site water treatment systems for each of these uses. Cooling water for new Unit # 8 will be supplied by the addition of cooling towers. The two existing CT's that will be converted into combined cycle operation are currently air-cooled. Makeup water for the pond is taken from the St. Lucie canal. The current makeup water quantity to the cooling pond (approximately 4,800 gpm) is expected to be adequate for the proposed expansion. Water quantities needed for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l. Water Supply Sources by Type

Martin Unit # 8 will utilize the existing on-site cooling pond as the source of cooling water for the cooling towers and as a heat sink for the dissipation of cooling water heat. The cooling pond operates as a "closed cycle" system in which heated water from the generating unit loses its heat as it is circulated within the pond and back around to the plant intake. Water is also collected in a seepage ditch surrounding the cooling pond and is then pumped back into the cooling pond. Makeup water to the pond is withdrawn from the St. Lucie canal as needed to replace net evaporation and seepage losses from the pond. Such needs will comply with the existing agreement between FPL and the South Florida Water Management District (SFWMD) regarding allocation of cooling water to the pond and with SFWMD's regulations for consumptive water use.

The existing water treatment system at the plant, which provides treated water for use in the Unit # 1 and # 2 boilers, as well as for the HRSG's associated with Units # 3 and # 4, will be used to provide treated water for Unit # 8.

m. Water Conservation Strategies Under Consideration

Impacts on the surficial aquifer will be reduced by changing the source of plant process water to the Floridan Aquifer upon completion of Unit # 8. In addition, the entire plant site captures and reuses process water whenever feasible and manages stormwater in such a manner so as to recharge the surficial aquifer.

n. Water Discharges and Pollution Control

Heated water discharges will be dissipated in the cooling pond. Non-point source discharges are not an issue since there are none at this facility. Industrial discharges will be minimized by treating and recycling equipment wash water, boiler blowdown water, and equipment area runoff. Storm water runoff is collected and used to recharge the surficial aquifer via a storm water management system. Design elements have been included to capture suspended sediments. Facility permits mandate various sampling and testing activities that provide indications of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by multiple fuel delivery facilities. However, the addition of new Unit # 8 will require an enlargement of the existing natural gas pipelines, the installation of a new pipeline, or the addition of another pipeline compressor station. There are currently two natural gas supply lines into the facility, as well as an oil pipeline, which serve the existing steam boilers and combined cycle generating units. Distillate fuel oil is also received by truck and stored in above ground storage tanks. The existing natural gas line also serves CT Units # 8a and # 8b.

p. Air Emissions and Control Systems

FPL's plan for Unit # 8 is subject to "New Source Review" under Federal and State Prevention of Significant Deterioration (PSD) regulations. This review requires these units to meet New Source Performance Standards (NSPS) and that Best Available Control Technology (BACT) be selected to control emissions of those pollutants emitted in excess of applicable PSD significant emission rates. The primary purpose of BACT analysis is to minimize the allowable increases in air pollutants taking into account energy, environmental, and economic impacts. This process provides for the potential for future economic growth without significantly degrading air quality.

q. **Noise Emissions and Control Systems**

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise would be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will also be within allowable levels.

r. **Status of Applications**

A Site Certification Application (SCA) was filed in December, 1989, for the construction and operation of the Martin Coal Gasification/Combined Cycle project under the Florida Electrical Power Plant Siting Act.

On June 15, 1990, the Public Service Commission issued a Determination of Need Order for proposed Martin Units # 3 and # 4. This determination of need applied to the additional 832 MW of combined cycle generation. The Siting Board issued a Land Use Order on June 27, 1990. The Certification Hearing was held on November 5-7, 1990. On February 12, 1991, the Governor and Cabinet, serving as the Siting Board, approved the construction and operation of natural gas-fired combined cycle Units # 3 and # 4 and determined that the Martin Site has capacity to accommodate additional combined cycle units fueled by natural gas or fuel oil.

Since the initial certification in 1991, the certification was modified five times through 1999 to provide authorization for items such as CT testing, increasing the cooling pond elevation, incorporating changes from other permits, and incorporating a custom fuel monitoring program. For the addition of the two simple cycle CT's mentioned above, FPL obtained a sixth modification to the existing site certification in August 2000.

In order to convert these two CT's from simple cycle to (4X1) CC configuration (Unit # 8), a seventh modification to the Site Certification is required. FPL filed the SCA on February 1, 2002 with the Florida Department of Environmental Protection (FDEP). A positive recommendation from the Administrative Law Judge for the project was received in early March of 2003. The certification process is expected to be completed with Governor and Cabinet's final review near the end of May 2003.

IV.F.2 Potential Sites

Five (5) sites are currently identified as potential sites for future generation additions to meet FPL's 2007 – on capacity needs.[2] These sites have been identified as "potential sites" due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these potential sites offers advantages and disadvantages relative to engineering considerations and/or costs associated with the construction and operation of feasible technologies. In addition, each potential site has different characteristics that could require further definition and attention. For purposes of estimating water usage amounts, it is assumed that a natural gas-fired CC unit would be the technology of choice for any capacity additions at the sites.

Permits are presently considered to be obtainable for all of these sites, assuming measures can be taken to mitigate any particular site-specific environmental concerns that may arise. No significant environmental constraints are currently known for any of these five sites. The potential sites briefly discussed below are presented in alphabetical order. At this time FPL considers each site to be equally viable.

Potential Site # 1: Cape Canaveral Plant, Brevard County

This site is located on the FPL Cape Canaveral Plant property in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway (US 1). A rail line is located near the plant. The existing facility consists of two 400 MW (approximate) steam boiler type generating units.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Cape Canaveral property site is found at the end of this chapter.

[2] As has been described in previous FPL Plant Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites.

b. and c. Land Uses and Environmental Features

This site is located on the Indian River. The land is primarily dedicated to industrial use with surrounding grassy areas and a few acres of remnant pine forest. The land adjacent to the site is dedicated to light commercial and residential use. There are no significant environmental features on the site.

d. and e. Water Quantities and Supply Sources

FPL projects that an increase of up to 260 gallons per minute (gpm) would be required for industrial processing use (boiler makeup, service water, etc.) It is expected that industrial cooling water needs could be met using the current 550,000 gpm once-through cooling water quantity. For industrial processing, FPL would use existing on-site wells or local gray water.

Potential Site # 2: Midway Substation Property, St. Lucie County

The site is located on the 122-acre Midway Substation property. Current facilities on the site include an electric substation. The site has direct access to a two-lane highway, State Road (SR) 712 and a nearby entrance to I-95. The City of Port St. Lucie is immediately east and west of the Midway site. The City of Ft. Pierce is approximately 9 miles northeast of the site.

a. U.S. Geological Survey (USGS) Map

A USGS map is provided of the Midway site area is provided at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is currently dedicated to industrial and agricultural use. Much of the site is currently not being used. Developed portions of the adjacent properties are primarily agricultural (orange groves and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and wetlands.

d. and e. Water Quantities and Supply Sources

No surface water source is available at this site. The water source would either be groundwater from the shallow aquifer or a local source of gray water. It is estimated that 150 gallons per minute (gpm) will be needed for industrial processing water for uses such an inlet air cooling, No_x control during light oil firing and for service water. Other facility water uses may include irrigation, potable use, etc. The total volume of these uses is estimated to be about 5 gpm.

Also, as part of the Everglades Restoration Project, a 500-acre retention pond (Ten Mile Creek Project) is scheduled to be completed near the proposed Midway site in mid-2004. It is possible that some water from this storage facility could be utilized for cooling to supplement ground water usage.

Potential Site # 3: Port Everglades Plant, Broward County

This site is located on the 94-acre FPL Port Everglades plant site in Port Everglades, Broward County. The site has convenient access to State Road (SR) 84 and Interstate 595. A rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (approximate) and two 400 MW (approximate) sized units. The four steam boilers are capable of firing residual fuel oil, natural gas, or a combination of both. The site also is home to twelve simple cycle gas turbine (GT) peaking units of 30 MW (approximate) each. The GT's are part of the Gas Turbine Power Park that is made up of 24 GT's at the Lauderdale Plant site and the twelve GTs at the Port Everglades site. The GT's are capable of firing either natural gas or liquid fuel.

a. U.S. Geological Survey (USGS) Map

A map of the Port Everglades plant site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on this site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

d. and e. Water Resources and Supply Sources

FPL estimates that up to 130 gallons per minute (gpm) of industrial processing water would be required for uses such as boiler makeup, fogger usage, and service water. FPL expects to use the existing municipal water supply for industrial process and makeup water. Cooling water would be drawn from the intercoastal waterway and cooling towers would be constructed.

Potential Site # 4: Riviera Plant, Palm Beach County

This site is located on the FPL Riviera Plant property in Riviera Beach, Palm Beach County. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (approximate) steam boiler generating units and one retired 50 MW generating unit.

a. U.S. Geological Survey

A USGS map of the Riviera plant site is found at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is primarily covered by the existing generation facilities with some open maintained grass areas. There is a small manatee viewing area on the site, which is operated seasonally by FPL. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development. The site is located on the Intracoastal Waterway near the Lake Worth Inlet.

d. and e. Water Quantities and Supply Sources

Additional industrial processing water needs are estimated to be up to 40 gallons per minute (gpm). Industrial cooling water needs are estimated to be up to 54,000 gpm using the existing once-through cooling water system. The existing municipal water supply would be used for industrial processing water if additional generating capacity is placed at Riviera. For once-through cooling water, FPL would continue to use Lake Worth as a source of water.

Potential Site # 5: Turkey Point Plant, Dade County

The Turkey Point Plant site is located on the West Side of Biscayne Bay 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of the nuclear and fossil plants, the cooling canals, an FPL-maintained natural wildlife refuge, and wetlands that have been set aside as an Everglades Mitigation Bank.

Units # 1 and # 2 are fossil fuel generating plants with approximate generating capacity of 400 MW each. Unit 1 was completed in 1967 and Unit # 2 in 1968. Turkey Point also has five diesel peaking units that in total produce approximately 12 MW. These units are primarily used to provide emergency power, but occasionally run during the Summer to provide power during peak load demands.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Turkey Point plant site, is found at the end of this chapter.

b. and c. Land Uses of Site and Environmental Features

A major portion of the site consists of a self-contained cooling canal system that supplies water to condense steam used by the existing units' turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide and four feet deep. The remaining developed area of the site is where the two fossil steam generating units and 5 diesel generators are located. Adjacent to the fossil plant are the two nuclear generating units. To the south, wetlands have been set aside as part of the Everglades

Mitigation Bank in an effort to restore these areas to historical plant communities and hydrological function.

d. and e. Water Resources and Supply Sources

The additional quantity of water for industrial processing is estimated to be 150 gpm for plant process and service water. Water for this type of use would be supplied by a county water system. The current plant water treatment system, which provides treated water for use in Units # 1 and # 2 boilers, would likely be expanded.

Water for cooling would likely by supplied by the existing closed loop cooling canal system, although reclaimed water from a nearby publicly owned treatment works could possibly be utilized, if available. Cooling towers may also be used.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten-Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission constraints. External constraints deal with FPL's ties to its neighboring systems. Internal constraints deal with the flow of electricity within the FPL system.

The external constraints are important since they affect the development of assumptions for the amount of external assistance which is available and the amount and price of economy energy purchases. Therefore, these external constraints are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission constraints or limitations are addressed by identifying potential geographic locations for potential new units that may not adversely impact, or that may even alleviate, such constraints and limitations and in developing the costs for siting new units at different locations. Both site-and system-related transmission costs are developed for each different unit/unit location option or groups of options.

FPL's annual transmission planning work determines transmission additions needed to address constraints and to maintain/enhance system reliability. FPL's transmission plans are presented in Section III.E.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

As discussed in Chapter III of this document, FPL typically performs economic analyses of competing resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI) and Stone and Webster Management Consultants, Inc. The resource plan reflected in this document emerged as the resource plan with the least impact on FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach) and on the present value of revenue requirements for the FPL system.[3]

No sensitivity case analyses based on different load forecasts were carried out during FPL 's most recent planning work. This is due to the fact that the most economical options are combined cycle (CC) units. If higher – than – projected loads begin to appear, the combustion turbine components of any of the CC options could be placed in service early in simple cycle mode. FPL believed that this fact qualitatively enabled it to be able to address higher – than – projected loads.

[3] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases (as in FPL's current resource planning work), FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its base case or "Most Likely" fuel price forecast are discussed in Chapter III of this document.

In its most recent planning work, FPL did not test the sensitivity of its resource plan to a "Low Price" fuel forecast in conjunction with a "High Load" forecast. All of the options considered in the IRP analysis were gas-fired units, so any change in the fuel costs projections would have affected these options in essentially the same way. Consequently, FPL did not believe that a fuel price sensitivity case was needed.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

For the same reason given in response to Discussion Item #3, FPL did not conduct a "constant fuel differential" sensitivity analysis in its most recent planning work.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, and capacity output ratings and heat rate information. Schedule 1 and Schedule 8 present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add over the planing horizon is presented on the Schedule 9 forms.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

The key financial assumptions used in FPL's most recent resource planning work were 45% debt and 55% equity FPL capital structure, projected debt cost of 7.4%, and an equity return of 11.7%. These assumptions resulted in a weighted average cost of capital of 9.8% and an after-tax discount rate of 8.5%. In its recent planning work, FPL did not test the sensitivity of its resource plan to varying financial assumptions. The reason for this is that FPL's planning work focused on FPL construction options only that were generally very similar in design and varied only by site. Consequently, varying financial assumptions would have resulted in little/no change in the analysis results.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). However, in its most recent planning work FPL utilized a net present value of system revenue requirements as the basis for comparing options and plans. (As discussed in response to Discussion Item # 2, both the electricity rate basis and the system revenue requirement basis are identical when DSM levels are unchanged between competing plans. Such was the case in FPL's recent planning work.)

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two generation reliability criteria in its resource planning work. One of these is a minimum 15% Summer and Winter reserve margin for years up to mid – 2004 that changes to a minimum 20% Summer and Winter reserve margin for the mid – 2004 – on time period. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the planning criteria established by the North American Electric Reliability Council (NERC) in its *Planning Standards*. FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Planning Standards* are available on the internet (http://www.nerc.com/~filez/pss-psg.html).

In addition, FPL has developed a Facility Connection Requirements (FCR) document as well as a Facility Rating Methodology document that are also available on the internet (http://www.floasis.siemens-asp.com/oasis/fpl/info.htm).

Thermal ratings for specific transmission lines or transformers are found in the load flow cases that are available on the internet (http://www.floasis.siemens- asp.com/oasis/fpl/info.htm).

The normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138, 500	0.95	1.05
230	0.95	1.06

There may have been isolated cases for which FPL may have determined it prudent to deviate from the general criteria stated above. The overall potential impact on customers, the probability of an outage actually occurring, as well as other factors may have influenced the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption are revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. Finally, FPL is careful to claim only program savings for the average life of the installed efficiency measure. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

Among the strategic or non-price factors FPL typically considers when choosing between resource options are the following: (1) fuel diversity; (2) technology risk; and (3) environmental risk.

Fuel diversity relates to two concepts, the diversity of sources of fuel (e.g., coal vs. oil vs. natural gas), and the diversity of supply for a single fuel source (for example alternative pipeline suppliers for natural gas). All other factors being equal, supply options that increase diversity in fuel source and/or supply would be favored over those that do not.

Technology risk is an assessment of the relative maturity of competing technologies, For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of competing technologies. Technologies which might be regarded as more acceptable from an environmental perspective (e.g., natural gas-fired options) might be considered more favorably.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed, the near – term elements of FPL's capacity additions include the repowering of one of its Sanford plants, the addition of new combustion turbines (CT's) at Fort Myers, and a number of firm capacity, short-term purchases. The incremental capacity from the repowering project comes from the addition of new CT's and heat recovery steam generators (HRSG's). FPL acquired the repowering-related CT's, plus the other new CT's for Fort Myers, and the HRSG's through a bid process which combined cost and performance considerations. The firm capacity short-term purchases were acquired through negotiations.

The 2005 capacity addition decision was arrived at after evaluating 134 bids received in response to two capacity Request for Proposals (RFP) issued by FPL in mid-2001 and mid-2002. The decision to construct new combined cycle units at FPL's existing Martin and Manatee sites was subsequently approved by the Florida Public Service Commission in late 2002.

The later (2007 – on) capacity additions are likely to be subject to a capacity solicitation process similar to the Request for Proposal (RFP) process that led to the selection of Martin Unit # 8 and Manatee Unit # 3. Identification of these self – build options in FPL's Site Plan is not an indication that FPL has prejudged any capacity solicitation it may conduct. It is merely a recognition of what currently appears to be FPL's best, most cost-effective self – build options at this time. FPL reserves the right to refine its planning analyses and to identify other self – build options. Such refined analyses have the potential to yield a variety of self – build options, some of which might not require an RFP. If an RFP is issued for supply – side resources, FPL reserve the right to choose the best alternative for its customers, even if that option is not an FPL self – build option.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new or upgraded line.

FPL's latest Transmission/Substation Expansion Plan for years 2002-2012 published in December, 2002 includes a new transmission line that is planned which would need to be certified under the Transmission Line Siting Act (403.52 – 403.536, F.S.). The new line will connect FPL's Orange River Substation to the Collier Substation. The construction of this line is necessary to serve existing and future customers in the Collier and Lee areas in a reliable and effective manner.

Additionally, contained in FPL's latest Transmission/Substation Expansion Plan for years 2002-2012 published in December, 2002 is a section entitled "Transmission System Long-Range Projects: 2008-2012. These projects are at this time only potential long-range transmission projects and are subject to change. The siting of future generation additions could have an impact on the necessity of such transmission projects. These proposed potential projects are not yet budgeted projects, are in the preliminary stages of consideration, and are based upon current assumptions that will be monitored and adjusted in future planning assessments. No determination has been made with regard to these potential long-range projects as to whether they will need to be certified under the Transmission Line Siting Act (403.52 – 403.536, F.S.).

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the State of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten - Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and a disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with Rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (FAC).

This Ten - Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) planning analyses that were carried out in 2003 and that were completed in the first quarter of 2004. The forecasted information presented in this plan addresses the 2004 – 2013 time frame.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as needed as part of the Florida site certification process, or through other proceedings and filings.

This document is organized in the following manner:

Executive Summary

The Executive Summary provides a review of the major findings and conclusions presented in the Site Plan.

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

This chapter presents FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, particularly new capacity resources, as determined in FPL's IRP work in 2003 and early 2004.

Chapter IV – Environmental and Land Use Information

This chapter presents environmental information as well as preferred and potential site locations for additional electric generation facilities.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to specific information included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2004 Ten - Year Power Plant Site Plan (Site Plan) summarizes FPL's analysis of and plan to address a need for increased electric generation capability. This plan is part of FPL's efforts to meet projected incremental resource needs for the 2004 – 2013 time period.

FPL's integrated resource planning process has identified continued load growth in the FPL service territory in the next ten years. As a result, FPL's total generation capability is expected to significantly increase in response to this need during the 2004 – 2013 time period as shown in Table ES.1. This table also shows the resulting projected Summer and Winter reserve margins for FPL over this ten-year time horizon. Table ES.1 includes FPL's planned changes to existing generation units (due to unit overhauls, etc.), currently scheduled changes in the delivered amounts of purchased power, and the planned additions of new generating units. Although not specifically shown in this table, FPL's approved DSM Goals at the time this Site Plan was filed are assumed to be implemented on schedule.

The amount of new generating capacity that will be added is driven in part by the outcome of the Florida Public Service Commission (FPSC) docket No. 981890-EU. This docket ended with a stipulated agreement that resulted in FPL, along with Tampa Electric Company and Florida Power Corporation, changing its minimum reserve margin planning criterion from 15% to one of 20% beginning with the Summer of 2004. The following summarizes the capacity resources that are a part of FPL's 2004 Site Plan.

Based on previous actions, FPL has obtained the capacity needed over the next several years through a number of short-term, firm capacity purchases from utilities and other entities. Additional short-term, firm purchases for 2004 have been made and the balance will be completed by June 1.

In 2005, FPL will be adding a large (1,107 Summer MW) new combined cycle (CC) unit at its existing Manatee plant site. Also in 2005, the two combustion turbines (CT's) that were added at FPL's existing Martin plant site in mid - 2001 will be converted into a 1,107 Summer MW CC unit by the addition of two additional CT's, heat recovery steam generators, and associated equipment. This conversion will add 785 Summer MW of capability above the present capability of the existing two CT's. The additions for 2005 were selected as the best options among other FPL construction alternatives and numerous proposals received in response to two Request for Proposals (RFP's) FPL issued in August 2001 and April 2002, respectively. These two capacity additions were approved by the FPSC on November 19, 2002, and their applications for certification under the Florida Electric Power Plan Siting Act (PPSA) were granted on April 11, 2003.

In 2007, FPL forecasts a capacity need of 1,066 MW of additional capacity. FPL developed a plan for a 1,144 MW CC unit located at FPL's existing Turkey Point plant site as its next planned generating unit. Following a review of proposals received in response to FPL's 2003 RFP (issued in August, 2003), the FPL next planned generating unit (NPGU) was chosen as the best alternative. FPL filed for FPSC approval of a Determination of Need for this unit on March 8, 2004, and an FPSC decision on this matter is expected in mid-Summer of 2004. FPL filed for PPSA certification for this unit on November 14, 2003 and expects a decision on this application in the 1st Quarter of 2005.

FPL forecasts a continued need for new capacity in the years 2008 through 2013. In response to this continued need, and to facilitate system planning efforts, FPL's current plans include the addition of two combustion turbines (CT's) in 2008 at its Midway site, a CC unit in 2009 at its Corbett site, and two additional CC units: one each year in 2011 and 2012. Sites for these two additional CC units have not yet been selected. These planned increases in electric generation capability will allow FPL to maintain system reliability and integrity at a reasonable cost.

FPL's planning efforts in the past few years have also identified two issues that continue to receive attention in FPL's ongoing resource planning work. These two issues are: 1) the growing imbalance in southeast Florida between load and generating capacity located within this region; and 2) maintaining/enhancing fuel diversity in the FPL system. The selection of the Turkey Point CC unit to meet FPL's 2007 need will help mitigate the southeast Florida imbalance. FPL's approach to these two issues is discussed throughout this document and will continue to influence FPL's on-going resource planning work.

Projected Capacity Changes and Reserve Margins for [illegible]L [1]

		Net Capacity Changes (MW)		FPL Reserve Margin (%)	
		Winter [2]	Summer [3]	Winter	Summer
2004	Purchases [4]	(127)	44	27%	21%
	New Short-Term Purchase [5]	—	360		
	Changes to existing Units	21	74		
2005	Purchases [4]	(16)	(60)	22%	26%
	Manatee Unit #3 Combined Cycle [6]	—	1,107		
	New Short-Term Purchase [5]	—	(360)		
	Conversion of MR #8 CT's to CC [6]	(363)	785		
2006	Manatee Unit #3 Combined Cycle [6]	1,201	—	31%	22%
	Conversion of MR #8 CT's to CC [6]	1,198	—		
	Purchases [4]	(136)	(136)		
	Changes to existing Units	(2)	(1)		
2007	Purchases [4]	—	(945)	28%	20%
	Turkey Point Combined Cycle #5 [6]	—	1,144		
	Changes to existing Units	(1)	(2)		
2008	Purchases [4]	(1,018)	—	26%	20%
	Turkey Point Combined Cycle #5 [6]	1,181	—		
	Combustion Turbines at Midway	—	324		
	Changes to existing Units	(1)	—		
2009	Combustion Turbines at Midway	362	—	26%	23%
	Purchases [4]	—	(51)		
	Combined Cycle at Corbett [6]	—	1,144		
2010	Combined Cycle at Corbett [6]	1,181	—	28%	20%
	Purchases [4]	(51)	(975)		
	New Purchase(s)	—	931		
2011	Unsited Combined Cycle # 1 [6]	—	1,144	25%	22%
	Purchases [4]	(1,020)	(45)		
	New Purchase(s)	931	—		
2012	Unsited Combined Cycle # 1 [6]	1,181	—		
	Unsited Combined Cycle # 2 [6]	—	1,144	27%	25%
2013	Unsited Combined Cycle # 2 [6]	1,181	—	30%	22%
	TOTALS =	5,702	5,627		

1) Additional information about these resulting reserve [illegible]rgins and capacity changes are four[illegible] [illegible]n Schedules 7 & 8 respectively.

2) Winter values are values for January of year shown.

3) Summer values are values for August of year shown.

4) These are firm capacity purchases. See Section I.D and III.A. for more details.

5) Negotiations are currently underway between FPL and several parties to secure this short - term capacity

6) All new combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

Table ES.1

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8,070,000 people. FPL served an average of 4,117,221 customer accounts in thirty-five counties during 2003. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management, and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville. The current generating facilities consist of four nuclear steam units, three coal units, nine combined cycle units, seventeen fossil steam units, fifty-one combustion gas turbines, and five diesel units. The location of these units is shown on Figure I.A.1.

The bulk transmission system is composed of 1,105 circuit miles of 500 Kilovolt (KV) lines (including 75 miles of 500 KV lines [two 37-1/2 mile lines] between Duval Substation and the Florida-Georgia state line, which are jointly owned with Jacksonville Electric Authority) and 2,744 circuit miles of 230 KV lines. The underlying network is composed of 1,634 circuit miles of 138 KV lines, 719 circuit miles of 115 KV lines, and 178 circuit miles of 69 KV transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 526 substations.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

Capacity Resources
(as of December 31, 2003)

Non-FPL Territory

	Unit Name	No. of Units	Fuel Type	Summer Megawatts
A	Turkey Point	2	Nuclear	1,386
B.	St. Lucie *	2	Nuclear	1,553
C.	Manatee	2	Oil/Gas	1,628
D.	Ft. Myers	1	Oil/Gas	1,423
E.	Turkey Point	2	Oil/Gas	807
F.	Cutler	2	Gas	206
G.	Lauderdale	2	Gas/ Oil	859
H.	Port Everglades	4	Oil/Gas	1,233
I.	Riviera	2	Oil/Gas	565
J.	Martin	4	Gas/Oil	2,592
K.	Cape Canaveral	2	Oil/Gas	814
L.	Sanford	3	Gas/ Oil	2,018
M.	Putnam	2	Gas/Oil	498
N.	St. Johns River *	2	Coal/Pet Coke	254
Scherer **		1	Coal	658
Peaking Units				2,562
FPL Generation				19,056

**Represents FPL's ownership share: St. Lucie nuclear: 100% unit 1, 85% unit 2; St. Johns River: 20% of two units.*

*** The Scherer unit is located in Georgia and is not shown on this map.*

I.B Non-Utility Generation

Non-utility generation is an important part of FPL's resource mix. FPL currently has contracts with seven cogeneration/small power production facilities to purchase firm capacity and energy. A listing of these facilities appears in Table I.B.1. In addition, FPL purchases as-available (non-firm) energy from several cogeneration facilities and small power production facilities as shown in Table I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Florida Power & Light Company Firm Capacity and Energy Contracts with Cogeneration/Small Power Production Facilities					
Project	**County**	**Fuel**	**Capacity MW**	**In-Service Date**	**End Date**
Bio-Energy	Broward	Landfill Gas	10.0	5/1/1998	01/01/05

Table I.B.2

I.C. Demand Side Management (DSM)

FPL's DSM activities continue what has been FPL's practice since 1978 of encouraging cost-effective conservation and load management. FPL's DSM efforts through 2003 have resulted in a cumulative Summer peak reduction of approximately 3,270 MW at the generator and an estimated cumulative energy saving of 25,429 GWH at the generator.

FPL's current DSM Plan was approved by the Florida Public Service Commission in late 1999 and reflects FPL's DSM Goals for the 2000-2009 time frame. FPL's resource plan, and the schedule for new generation additions, presented in this document are based on these approved DSM levels.

I.D. Purchased Power

Purchased power is also an important part of FPL's resource mix. FPL has a Unit Power Sales (UPS) contract to purchase 931 MW, with a minimum of 381 MW, of coal-fired generation from the Southern Company through May, 2010. In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) for the purchase of 381 MW (Summer) and 390 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Unit Nos. 1 and 2 (FPL also has ownership interest in these units; that ownership amount is reflected in FPL's installed capacity shown on Schedule 1).

Finally, FPL has additional firm capacity purchase contracts through early 2007. These firm capacity purchase contracts are with a variety of suppliers. Table I.D.1 presents a projection of firm purchased power contracts through the year 2013.

	FPL's Purchased Power MW (1)							
	UPS		***SJRPP***		***Other Firm Capacity Purchases***		***Total***

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are developed on an annual basis for resource planning work at FPL. These forecasts are a key input to the models used to develop the Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

The primary drivers to develop these forecasts are demographic trends, weather, economic conditions, and prices of electricity. In addition, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from the National Oceanic and Atmospheric Administration (NOAA), and inputs from FPL's own customer service planning areas. In the area of demographics, population trends by county, plus housing characteristics such as housing starts, housing size, and vintage of homes are assessed.

Forecasts for electric usage in the residential and commercial classes include end-use information such as appliance saturation studies, efficiencies, and intensity of energy use. In addition to these inputs, residential forecasts also make use of household characteristics such as ages of members in households, number of members in households, and income distributions.

The projections for the national and Florida economy are obtained from Global Insight, formerly know as DRI - WEFA. Population projections for the counties served by FPL are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. In addition, FPL actively participates with local development councils and universities to obtain their assessments of the local economy, specifically in the area of expansion of new businesses and retention of the current business base. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is a key factor that affects the company's sales and peak demand. Weather variables are used in the forecasting models for energy sales and peak demand. There are two sets of weather variables developed and used in forecasting models:

1. Cooling and Heating Degree-Days are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric heaters. A composite temperature is derived using hourly temperatures across FPL's service territory (Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained) weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Days which are based on starting point temperatures of 72°F and 66°F, respectively. Similarly, the maximums and minimums of the composite temperature are used for the Summer and Winter peak models.

II.A. Long-Term Sales Forecasts

Long-term forecasts of electricity sales were developed for each revenue class for the forecasting period of 2003-2025 and are adjusted to match the Net Energy for Load (NEL) forecast. The results of these sales forecasts for the years 2004 - 2013 are presented in Schedules 2.1 - 2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical tool MetrixND. The methodologies used to develop sales forecasts for each jurisdictional revenue class are outlined below. The first five years of the forecasts were developed using monthly models for Net Energy for Load and energy sales by class.

1. Residential Sales

Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted. Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, Florida per capita income, and Cooling and Heating Degree-Days as explanatory variables. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. The Cooling Degree-Days variable is multiplied by the level of air conditioning saturation and the Heating Degree-Days variable is multiplied by the level of electric heating saturation. To capture economic conditions, the model includes Florida's per capita income. The degree of economic prosperity can, and does, affect residential electricity sales. For the short-term period (first five years), an econometric model is developed using monthly data. The monthly model is a function of the same variables such as Cooling Degree-Days, Heating Degree-Days, price of electricity, Florida's per capita income, and a dummy variable for the months of April, May, and October.

2. Commercial Sales

The commercial sales forecast is also developed using a regression model for the long-and short-term. Commercial sales are a function of the following variables: Florida's commercial employment, commercial real price of electricity, Cooling Degree-Days, and an autoregressive term. Florida's commercial employment is used to capture the economic activity in FPL's service territory. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree-Days are used to capture weather-sensitive load in the commercial sector. The first five years of the forecast are developed from a monthly model using the same explanatory variables, and for the following years, growth rates from the annual model are applied.

3. Industrial Sales

Industrial sales are forecasted through a linear multiple regression model using Florida manufacturing employment, the price of electricity, and a dummy variable for the economic recessions. Energy sales in this revenue class are primarily due to manufacturers; therefore, employment in this sector is a key variable in capturing the economic activity. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. For the short-term period (first five years), an econometric model is developed using monthly data. The monthly model is a function of the same variables such as Florida manufacturing employment, Cooling Degree-Days, price of electricity, and an autoregressive term. For the following years, growth rates from the annual model are applied.

4. Other Public Authority Sales

At present, this class consists of sports fields and one government account. The forecast for this class is based on historical knowledge of its characteristics.

5. Street & Highway Sales and Railroad & Railways Sales

The forecast for Street and Highway sales is developed by first assuming a constant use per customer and then multiplying that value by the number of projected customers. The forecast of sales to Railroad & Railways is based on historical knowledge of its characteristics. This class consists of Miami-Dade County's Metrorail system.

6. Sales for Resale

Sales for Resale (Wholesale) customers are composed of municipalities and/or electric cooperatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Currently, there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of Key West, Florida (City of Key West), Miami-Dade County, and FMPA. Sales to the Florida Keys are forecasted using a regression model. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor. Miami-Dade County sells 60 MW to Florida Power Corporation. Line losses are billed to Miami-Dade under a wholesale contract. The forecast is calculated based on assumptions about the magnitude of line losses, the sales monthly capacity factor, and the number of hours in a particular month. FMPA has contracted for delivery of 75 MW through October, 2007.

7. Total Sales

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual Net Energy for Load (NEL).

II.B. Net Energy for Load

An annual econometric model is developed to produce a Net Energy for Load (NEL) forecast. The key inputs to the model are: the price of electricity, Heating and Cooling Degree-Days, Florida Non-Agricultural Employment, and an autoregressive term. The monthly model is similar, except the economic variable utilized is Florida's per capita income since the model is estimated on a per customer basis. Like the sales forecasts, the first five years are obtained from the short-term model, and forecasts for subsequent years are generated using the growth rates from the annual model.

Once an annual NEL forecast is obtained using the above-mentioned methodology, the results are then compared for reasonableness to the NEL forecast generated using the total sales forecast. The sales by class forecasts previously discussed are then adjusted to match the NEL from the annual NEL model.

The forecasted NEL values for 2004 – 2013 are presented in Schedule 3.3 that appears at the end of this chapter.

II.C. System Peak Forecasts

The rate of absolute growth in FPL system load has been a function of a larger customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the Peak Forecast models to capture these behavioral relationships.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2004 – 2013 are presented in Schedules 3.1 and 3.2 as well as in Schedules 7.1 and 7.2.

1. System Summer Peak

The Summer peak forecast is developed using an econometric model. The model is a per customer model that includes: the total number of FPL's customers, the price of electricity, Real Florida income as an economic driver, and the maximum temperature as a weather variable. Also included in the model is an autoregressive term.

2. System Winter Peak

Like the system Summer peak model, the Winter peak model is also an econometric model. The Winter peak model is a per customer model which consists of three weather-related variables: (1) the minimum Winter day temperature, (2) a weather term, which is a ratio of heating saturation and minimum Winter day temperature, and (3) Heating Degree-Hours for the prior day until 9:00 a.m. of the peak day. In addition, the model also uses an economic variable, Real Florida Income. A dummy variable, which is used to capture the effects of larger homes, is multiplied by the minimum temperature.

3. Monthly Peak Forecasts

Monthly peaks for the 2003-2025 period are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peak (Summer = April-October, Winter = November-March.)

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.D. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2003-2025 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. These daily load shapes are ranked and used with forecasted monthly peaks, NEL, and calendars in developing an hourly forecast. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load-to-peak ratio is maintained.

2013	24,784	159	24,625	0	830	321	623	148	22,862

Historical Values (1994 - 2003):

Col. (2) - Col.(4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) -Col. (9) represent actual DSM capabilities starting from January 1988.
Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business on Call (BOC) and Commercial Demand Reduction (CDR).

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8).

Projected Values (2004 - 2013):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2003 are incorporated into the forecast.

Col. (5) - Col. (9) represent all incremental conservation and cumulative load control. These values are projected August values and are based on projections with a 1/2003 starting point.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990's and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be considered. The projected timing and type of potential new power plants, the primary subject of this document, is determined as part of the IRP process work. This section discusses how FPL applied this process in its 2003 and early 2004 planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's projected new resource needs;

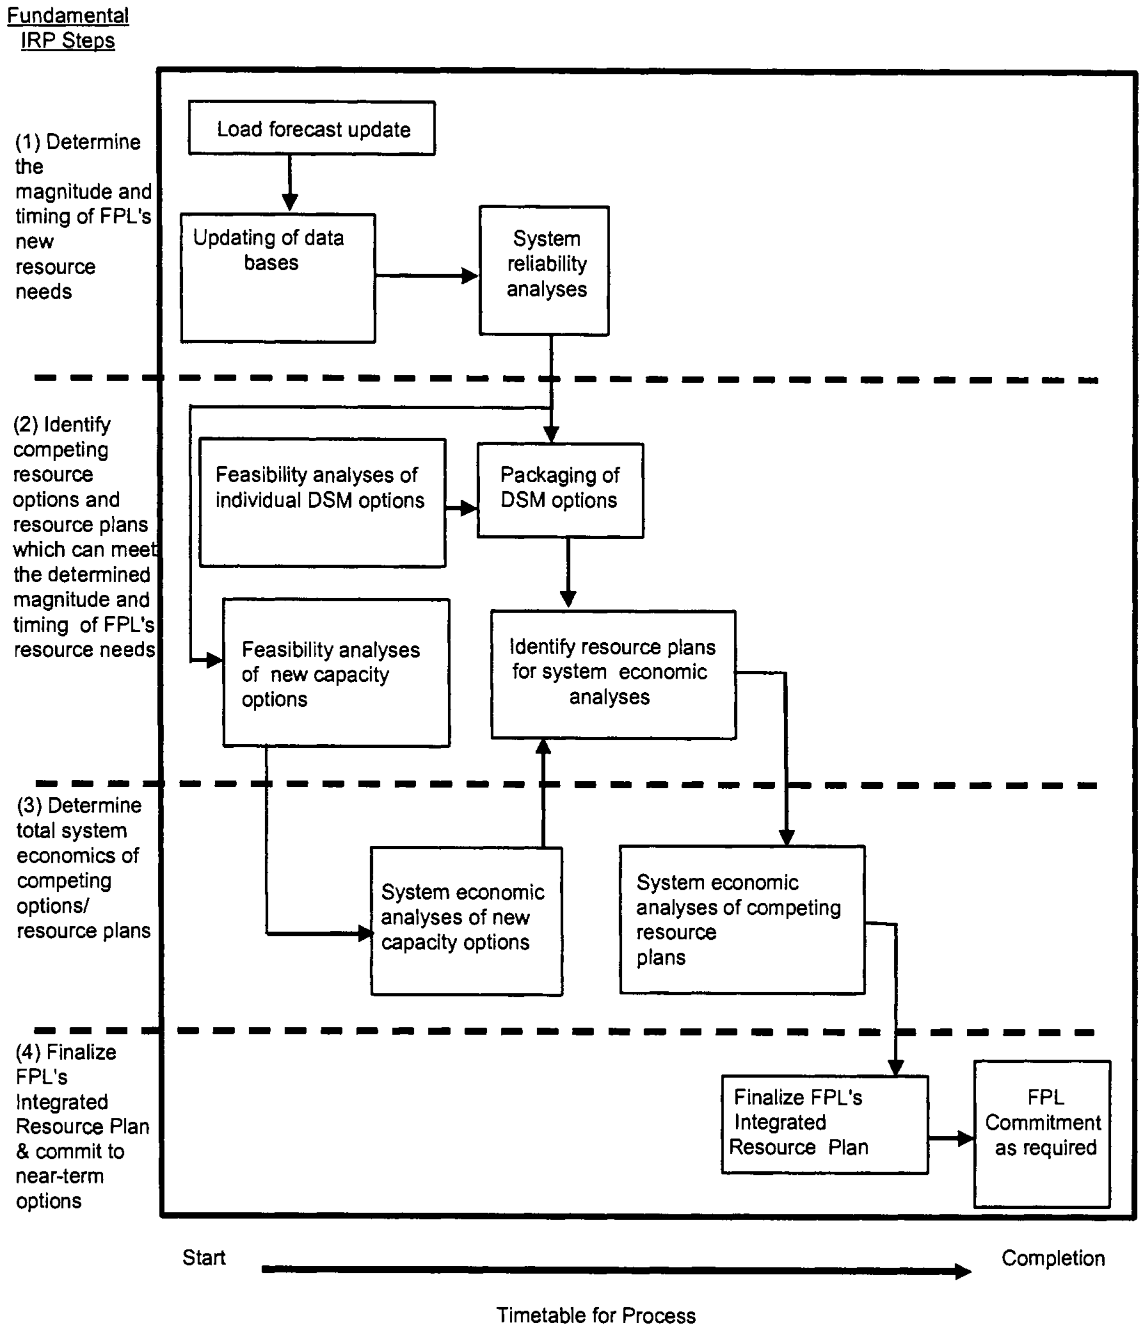
Step 2: Identify which resource options can meet the determined magnitude and timing of the specific resource needs;

Step 3: Determine the economics for the total utility system with each of the competing options and resource plans; and,

Step 4: Select a resource plan and make commitments, as required.

Figure III.A.1 graphically outlines the 4 steps.

Overview of FPL's IRP Process



(Normal time period: approx. 6-7 months)

Figure III.A.1

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps – determining the magnitude and timing of FPL's projected resource needs – is essentially a determination of how many megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions are expected to be needed. Also determined in this step is when the capacity is expected to be needed to meet FPL's planning criteria. This step is often referred to as a reliability assessment for the utility system.

Step 1 generally starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information which is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, as well as power plant capability and reliability assumptions. During its recent IRP work, FPL made four key assumptions. These assumptions include near-term construction capacity additions through the summer of 2007, short-term firm capacity purchase additions through late spring of 2007, long-term DSM implementation through 2009, and the projected replacement of the Southern Company Unit Power Sales (UPS) contracts that end in May, 2010.

The first of these assumptions incorporates FPL's announced plans to add near-term capacity through various construction projects. These construction projects include the addition of a new combined cycle (CC) unit at Manatee, the conversion of two existing CT's at Martin into a new CC unit and a new CC unit at Turkey Point. The Manatee and Martin additions are under construction with a scheduled in-service date of June, 2005. These capacity additions were approved by the FPSC in November 2002 after comparing them to proposals that were received in response to Requests for Proposals (RFP's) that solicited alternatives for meeting FPL's 2005/2006 capacity needs. These capacity additions also received certification under the Florida Electrical Power Plant Siting Act (PPSA) in April, 2003. The new CC unit at FPL's Turkey Point site is scheduled for mid-2007. FPL selected this construction option after evaluating competing proposals provided in response to FPL's 2003 RFP. FPL recently (March 8, 2004) filed for a request for approval of a Determination of Need for this unit with the FPSC and also has pending an application for PPSA certification of this unit with a decision expected in the 1st Quarter of 2005.

The second of these assumptions involves short-term firm capacity purchase additions. These firm capacity purchases are provided by a combination of utility and independent power producers. The total capacity and duration of these purchases have changed somewhat from what was presented in the 2003 Site Plan and the annual total capacity values for these purchases are presented in Table I.D.1 as "Other Firm Capacity Purchases" up to mid-2007. These purchase amounts are included in FPL's resource planning work.

The third of these assumptions involves DSM. Since 1994, FPL's resource planning work has incorporated the DSM MW called for in FPL's approved DSM goals in its analyses. This was again the case in FPL's most recent planning work, as its approved DSM goals at the time this Site Plan was filed were included.

The fourth of these assumptions anticipates a replacement of the UPS purchases that are currently scheduled to end in May, 2010 with other purchases. These purchases are presented in Table I.D.1 as "Other Firm Capacity Purchases" for the years beyond mid-2010.

These assumptions and much of the other updated information are used is the first fundamental step: the determination of the magnitude and the timing of FPL's projected resource needs. This determination is accomplished by system reliability analyses which are typically based on the dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both summer and winter peaks) and a maximum loss-of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry.

Historically, both deterministic and probabilistic methodologies have been employed in system reliability analysis. The calculation of excess firm capacity at the time of annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. The reserve margin calculation provides an indication of how much extra generation a system has above the forecasted peak load. A value of 20% is used as the reserve margin planning criteria to establish FPL's need. However, deterministic methods do not take into account probabilistic-related elements such as unit reliability and the value of being part of an interconnected system. Therefore, probabilistic methodologies have been used to provide additional information on the reliability of a generating system.

There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss-of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year and FPL uses this LOLP standard. LOLP analyses require complex statistical calculations and are carried out using the Tie Line Assistance and Generation Reliability (TIGER) model.

The end result of the first fundamental step of resource planning is a forecast of the amount and timing of capacity resources needed to meet both the reserve margin and LOLP criteria for system reliability. This information is used in the second fundamental step: identifying resource options and resource plans that can meet the projected magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans which can meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analyses of new capacity options are carried out to determine which new capacity options appear to be the most economic. These analyses also consider capacity size (MW), estimated development and construction schedules, and operating parameters and costs.

The individual new capacity options are then "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new projected resource needs are met and the planning criteria are satisfied. The creation of these competing resource plans is typically carried out using dynamic programming techniques with the objective of forming alternative resource plans within the constraints applied to the resource planning process. The constraints include recognition of reserve margin criteria, feasible resource option performance characteristics, and construction or DSM implementation lead time. The development of these resource plans has been conducted using the EGEAS (Electric Generation Expansion Analysis System) computer model. When DSM options are being addressed, other computer models using both linear and non-linear programming techniques are used. For planning purposes, only FPL construction options were included in FPL's most recent planning analyses addressing FPL's 2008-2013 forecasted capacity needs.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs were identified.

Step 3: Determining the Total System Economics:

At the completion of fundamental steps 1 & 2, viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for comparing the system economics of these resource plans. The EGEAS model is employed to conduct the basic economic analyses of the resource plans.

The basic economic analysis of the competing resource plans focuses on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases such as those existing for FPL's most recent planning work (wherein the DSM contribution was incorporated and the only competing options were new generating units) comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. This basic economic analysis captures the capital and operating costs of new resource options as well as the impact these new resource options have on FPL's system fuel costs.

In addition, other system costs of these resource plans must be incorporated as needed into the economic analyses. These include transmission-related costs, such as integration and system losses; increased operating costs of existing generating units, and impacts on FPL's capital structure. These costs are evaluated separately and in addition to the system operating cost values developed in the EGEAS analysis to complete the system cost impact of each resource plan. FPL considered the results of all of the economic analyses carried out in Step 3, before a determination of FPL's resource plan was made.

Step 4: Finalizing FPL's Current Resource Plan

The results of the work performed in the previous three fundamental steps are evaluated by FPL management and a decision is made establishing FPL's resource plan. The current resource plan is presented in the following section.

III.B Resource Additions

FPL's preliminary plan for generation capacity additions and changes for the period 2004 through 2013 are depicted in Table III.B.1 (the planned DSM additions are shown separately in Table III.D.1). These capacity additions and changes will result from a variety of actions including: minor changes to existing units (such as plant component wear between maintenance activities or component replacements as part of maintenance activities), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules, the expiration of contracts, the addition of new purchase contracts, projected construction of new units, and conversion of the CT's at Martin into a CC unit.

As shown in Table III.B.1, the bulk of the capacity additions are made up of the following items:

- the conversion of two CT's into a larger CC unit in 2005 at FPL's Martin site
- the addition of a new CC unit, also in 2005, at FPL's Manatee site
- the projected construction of a new CC unit in 2007 at FPL's Turkey Point site
- the projected construction of 2 new CT units at the Midway site in 2008
- the projected construction of a new CC unit at the Corbett site in 2009
- the projected construction of two additional, unsited CC units, one each in 2011 and 2012.

These projected capacity additions address the forecasted resource needs from FPL's reliability analyses. In 2008, FPL's forecasted resource need is approximately 350 MW. For each year from 2009 through 2013, the projected annual resource need is significantly larger; between 550 MW to 630 MW per year.

In the past several years, FPL has undertaken several plant conversion and new construction activities that will result in the addition of approximately 6,600 MW of high efficiency, low emission combined cycle baseload generating capacity by 2007. Furthermore, as part of these plant conversions, FPL has transformed over 1,600 MW of previously intermediate and peaking generating capacity to high efficiency combined cycle base load capacity. Consequently, FPL currently plans that its relatively small 2008 need will be met by the construction of two CT units. Another factor contributing to this choice is the fact that FPL is in the process of developing proposed DSM Goals for the 2005 – 2014 period. FPL's DSM Goals will be filed with the FPSC in June 2004 and it is expected that the FPSC approval will be obtained no earlier than September 2004. The approved DSM Goals will then be utilized in subsequent analyses to finalize resource plans for 2008 and to evaluate resource plans to meet projected needs in 2009 and beyond. The current choice of new CT's to meet the 2008 need provides the flexibility to adopt the plan consistent with the DSM Goals that will be approved in late 2004 and will allow FPL to also consider meeting this need, in whole or in part, through one or more purchases from existing units.

Projected Capacity Changes and Reserve Margins for FPL (1)					
		Net Capacity Changes (MW)		FPL Reserve Margin (%)	
		Winter (2)	Summer (3)	Winter	Summer
2004	Purchases (4)	(127)	44	27%	21%
	New Short-Term Purchase (5)	---	360		
	Changes to existing Units	21	74		
2005	Purchases (4)	(16)	(60)	22%	26%
	Manatee Unit #3 Combined Cycle (6)	---	1,107		
	New Short-Term Purchase (5)	---	(360)		
	Conversion of MR #8 CT's to CC (6	(363)	785		
2006	Manatee Unit #3 Combined Cycle (6)	1,201	---	31%	22%
	Conversion of MR #8 CT's to CC (6)	1,198	---		
	Purchases (4)	(136)	(136)		
	Changes to existing Units	(2)	(1)		
2007	Purchases (4)	---	(945)	28%	20%
	Turkey Point Combined Cycle #5 (6)	---	1,144		
	Changes to existing Units	(1)	(2)		
2008	Purchases (4)	(1,018)	---	26%	20%
	Turkey Point Combined Cycle #5 (6)	1,181	---		
	Combustion Turbines at Midway	---	324		
	Changes to existing Units	(1)	---		
2009	Combustion Turbines at Midway	362	---	26%	23%
	Purchases (4)	---	(51)		
	Combined Cycle at Corbett (6)	---	1,144		
2010	Combined Cycle at Corbett (6)	1,181	---	28%	20%
	Purchases (4)	(51)	(975)		
	New Purchase(s)	---	931		
2011	Unsited Combined Cycle # 1 (6)	---	1,144	25%	22%
	Purchases (4)	(1,020)	(45)		
	New Purchase(s)	931	---		
2012	Unsited Combined Cycle # 1 (6)	1,181	---		
	Unsited Combined Cycle # 2 (6)	---	1,144	27%	25%
2013	Unsited Combined Cycle # 2 (6)	1,181	---	30%	22%
	TOTALS =	5,702	5,627		

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) These are firm capacity purchases. See Section I.D and III.A. for more details.

(5) Negotiations are currently underway between FPL and several parties to secure this short - term capacity.

(6) All new combined cycle units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

Table III.B.1

III.C Additional Issues Impacting FPL's Recent Planning Work

In the course of FPL's 2003 and early 2004 planning efforts, two issues that were identified in FPL's 2003 Site Plan received additional attention in FPL's on-going resource planning work. Those two issues are: 1) the need to address the growing imbalance in southeast Florida between load and generating capacity located within this region; and 2) the desire to maintain/enhance fuel diversity in the FPL system.

Southeast Imbalance

As was identified in previous FPL filings, there exists a significant imbalance between the large peak load in southeast Florida and the installed generating capacity in that region. The imbalance between generation and load is forecast to grow during the next few years because FPL forecasts continued load growth in this area beyond planned generation additions. If this growing imbalance is not addressed this will give rise to additional system costs that result from three transmission-related components: 1) increased transmission integration costs that will be required to deliver power to the load center from units outside the southeast Florida area, 2) the need to dispatch less efficient resources within the southeast Florida area and 3) the transmission losses associated with increased imports of electricity into the area.

Recognizing this load and generation imbalance in southeast Florida and the forecast of continued load growth in this area, FPL concluded it must either add generating capacity within this region or add the needed capacity outside of the southeast Florida area and the necessary transmission facilities to deliver capacity into southeast Florida. FPL's 2003 Request for Proposal (RFP) incorporated these concerns. The evaluation of FPL's Next Planned Generating Unit (NPGU) and proposals received in response to FPL's RFP addressed all system costs, including the three identified transmission-related cost components that are affected by the imbalance issue discussed above. Current and future resource planning processes also recognize these transmission-related costs associated with the geographic location of resource additions.

Fuel Diversity

Fuel diversity was the other key issue that received additional attention. In 2003, FPL began an evaluation of the economic and environmental characteristics of solid fuel-based technologies. Most economic analyses suggest that the forecasted fuel price differential between natural gas and solid fuel options might support the higher capital cost of solid fuel facilities. However, there remain at least three significant uncertainties inherent in the analyses that must be addressed and refined.

The first, and most influential, of these uncertainties is the forecasted behavior of the price differential between natural gas and solid fuels. Recognition of the high volatility exhibited by natural gas prices in recent years has added to the uncertainty of long - term price forecasts. Although continued growth in gas demand may contribute to higher firm gas prices, potential additional supply alternatives in the coming years (such as Liquefied Natural Gas - LNG) may contribute to lower gas prices. The extent to which these factors offset one another is a key influence that must be considered in this process. The second area of uncertainty is related to the type and cost of emissions management opportunities that will be available and the requirements that must be met during the operating life of a solid fuel facility. FPL's analyses of this area will address opportunities to employ evolving technologies to effectively manage the emissions of solid fuel facilities, the likely outcome of several significant legislative proposals that will impact the control level required, and managing the cost of compliance to FPL's customers in the future. Finally, FPL must address the uncertainty surrounding the capital cost and feasibility of developing and constructing a solid fuel facility in Florida. FPL is actively pursuing the refinement of data that will assist characterizing these uncertainties in a quantitative manner and incorporating this information into the resource planning process. FPL will provide to the FPSC, by December 2004, a report on FPL's evaluation regarding the possible addition of a solid fuel generation capacity in the future.

The current plan to meet FPL's projected capacity needs beyond 2007, reflected in the Tables and Schedules of this document, consists of the construction of natural gas - fired units, primarily CC's. The plan identifies this CC technology, in large part, because of its high efficiency and known benign environmental impact, as well as the high-level of development, construction, operational performance and capital cost forecasting confidence that has been accrued over recent years by FPL and the electric industry. Identifying this technology in FPL's current resource plan establishes a basis for which costs and risks are well understood and will allow the relative risks and benefits of competing alternatives to be more efficiently evaluated as detailed information and forecasts for those alternatives are refined. These projected resource additions beyond 2007 are subject to change pending the results of such evaluations.

FPL is actively engaged in identifying and evaluating opportunities that would enhance fuel and resource diversity in its capacity resource mix. These opportunities include:

- the construction of new solid fuel-based (coal and petroleum coke) facilities
- obtaining access to non-traditional sources of natural gas, such as through suppliers who transport and deliver natural gas to Florida in the form of LNG.
- maintaining the ability to utilize fuel oil at FPL's existing units.

Therefore, the new gas-fired CT and CC units currently shown as capacity additions for 2008 through 2013, and in particular for 2011 through 2013, are subject to change in the future as FPL evaluates the feasibility and cost-effectiveness of various alternatives to enhance fuel diversity. Based on current information, FPL believes that the earliest that fuel diversity could be enhanced by adding new solid fuel-based generating capacity would be mid-2011 based on the siting, development, permitting, construction, and commissioning timeline for this technology. In addition, FPL believes it is more likely that such a unit would be sited at some site north of southeast Florida due to permitting and fuel transportation considerations.

FPL's assessment of the fuel and resource diversity alternatives will continue to be developed through its on-going resource planning work and site development activities in 2004.

III.D Demand Side Management (DSM)

1. FPL's currently approved DSM programs are summarized as follows:

Residential Conservation Service: This is an energy audit program designed to assist residential customers in understanding how to make their homes more energy-efficient through the installation of conservation measures/practices.

Residential Building Envelope: This program encourages the installation of energy-efficient ceiling insulation in residential dwellings that utilize whole-house electric air conditioning.

Duct System Testing and Repair: This program encourages demand and energy conservation through the identification of air leaks in whole-house air conditioning duct systems and by the repair of these leaks by qualified contractors.

Residential Air Conditioning: This is a program to encourage customers to purchase higher efficiency central cooling and heating equipment.

Residential Load Management (On-Call): This program offers load control of major appliances/household equipment to residential customers, in exchange for monthly electric bill credits.

Residential New Construction (BuildSmart): This program encourages the design and construction of energy-efficient homes that cost-effectively reduce coincident peak demand and energy consumption.

Business Energy Evaluation: This program encourages energy efficiency in both new and existing commercial and industrial facilities by identifying DSM opportunities and providing recommendations to the customer.

Commercial/Industrial Heating, Ventilating, and Air Conditioning: This program encourages the use of high-efficiency heating, ventilation, and air conditioning (HVAC) systems in commercial/industrial facilities.

Commercial/Industrial Efficient Lighting: This program encourages the installation of energy-efficient lighting measures in commercial/industrial facilities.

Business Custom Incentive: This program encourages commercial/industrial customers to implement unique energy conservation measures or projects not covered by other FPL programs.

Commercial/Industrial Load Control: This program reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortage, in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

Commercial/Industrial Demand Reduction: This program, which started in 2002, is similar to the Commercial/Industrial Load Control program mentioned above in continuing the objective to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits.

Commercial/Industrial Building Envelope: This program encourages the installation of energy-efficient building envelope measures, such as window treatments and roof/ceiling insulation, for commercial/industrial facilities.

Business On Call: This program offers load control of central air conditioning units to both small, non-demand-billed and medium, demand-billed commercial/industrial customers, in exchange for monthly electric bill credits.

2. Research and Development

FPL's DSM Plan continues to support research and development activities. Historically, FPL has performed extensive DSM research and development. FPL will continue such activities, not only through its Conservation Research and Development program, but also through individual research projects. These efforts will examine a wide variety of technologies that build on prior FPL research where applicable and will expand the research to new and promising technologies as they emerge.

Conservation Research and Development Program

FPL's Conservation Research and Development Program is designed to evaluate emerging conservation technologies to determine which are worthy of pursuing for program development and approval. FPL has researched a wide variety of technologies and, from that research, has been able to develop new programs such as Residential New Construction, Commercial/Industrial Building Envelope and Business On Call.

Low Income Weatherization Retrofit Project

This R&D project investigated cost-effective methods of increasing the energy efficiency in the homes of FPL's low-income customers. The research project addressed the needs of low-income housing retrofits by providing monetary incentives to various housing authorities, including weatherization agency providers (WAPS), and non-weatherization agency providers (non-WAPS). These incentives were used by the housing authorities to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting.

The final report for this project was filed in November 2003. Of the seven different DSM measures evaluated, it was found that two measures, addressing HVAC maintenance and infiltration, were cost-effective. The Commission recently approved a permanent Low-Income Weatherization Program that includes these cost-effective measures. The research project will be discontinued upon the rollout of the permanent program.

Photovoltaic Research, Development and Education Project

Photovotaic (PV) roof-tile systems are a relatively new technology which directly replaces existing roofing materials such as shingles and standing-rib roofing with PV materials. These PV materials have the same waterproofing characteristics as conventional roofing materials. This project is consistent with the Federal Government's Million Solar Roofs Initiative. Based on FPL's research to-date a primary hurdle to the physical installation of PV systems, whether roofing materials or flat plate modules, is the lack of awareness, understanding and acceptance by local building officials. For the most part, these officials are unclear about how these systems work and how to address these systems as part of the building, permitting, and inspection process. This creates barriers toward the use of this technology. As part of this project, FPL has been holding workshops to address this issue. This project is scheduled to be completed in the first quarter of 2004.

Green Energy Project

Under this project, FPL has examined the feasibility of purchasing tradable renewable energy credits generated from new renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy and/or other renewable sources. Customers who participate would then be charged higher premiums for purchasing tradable renewable energy credits that are associated with electric energy generated by these sources.

Development of a Green Energy program was completed and FPL filed a petition for program approval with the FPSC in August 2003. As part of this process, a supply contract was put into place that allows FPL to match supply with customer demand for green energy. The FPSC approved the program on December 2, 2003 and program implementation began in the first quarter of 2004.

On Call Incentive Reduction Pilot

In March 2003, FPL received FPSC approval to perform a pilot project for its On Call program. Under the pilot project FPL is offering to new participants a residential load control service similar to the On Call Program at a reduced incentive level. This offering allows FPL to test its market research data and gauge whether FPL can repackage its current residential load control service, minimize customer attrition, achieve current goals for residential load control, and, ultimately, change On Call incentive levels without damaging system reliability.

3. **FPL's approved DSM Goals at the time this Site Plan was filed are listed below in Table III.D.1**

FPL's Summer MW Reduction Goals for DSM
(At the Meter)

Year	Goal Cumulative Summer MW
2000	122
2001	200
2002	269
2003	339
2004	410
2005	484
2006	554
2007	625
2008	697
2009	765

Table III.D.1

III.E Generation Additions from Independent Power Producers

As previously mentioned in Section III.A, FPL has a number of short-term, firm capacity purchases that extend through early 2007. The capacity supplied by these purchases is summarized in Table I.D.1. The vast majority of the capacity from these purchases is from independent power producers.

Tables I.B.1 and Table I.B.2 present the previously contracted cogeneration/small power production facilities which are addressed in FPL's resource planning.

III.F Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. Table III.F.1 presents FPL's proposed future additions of 230 kV and 500 kV bulk transmission lines including those corresponding to proposed generating facilities and those that must be certified under the Transmission Line Siting Act.

List of Proposed Power Lines

(1) LINE OWNERSHIP	(2) TERMINALS (To)	(3) TERMINALS (From)	(4) LINE LENGTH CKT. MILES	(5) COMMERCIAL IN-SERVICE DATE (MO/YR)	(6) NOMINAL VOLTAGE (kV)	(7) CAPACITY (MVA)
FPL	Andytown	Pennsuco	2	6/04	230	508
FPL	Bridge	Indiantown #2	10	12/04	230	759
FPL	Broward-Corbett	Rainberry-Yamato	11	6/04	230	759
FPL	Conservation	Oakland Park	13	6/05	230	759
FPL	Dade	Overtown	11	6/04	230	759
FPL	Indiantown	Martin #2	13	12/04	230	1067
FPL	Whidden	Vandola	27	6/04	230	1067
FPL	Collier	Orange River #3	54	12/05	230	759
FPL	West Palm Coast	St. Johns	23	6/08	230	759

Table III.F.1

In addition, there will be transmission facilities needed to connect a number of FPL's committed and projected capacity additions to the system transmission grid. These transmission facilities for the projected capacity additions at FPL's existing Manatee, Martin, Turkey Point, Midway, and Corbett sites are described below.

Since the projected capacity additions for 2011 and 2012 are as-yet unsited, no transmission facilities information is provided. This information will be provided in future Site Plan documents once sites are selected.

III.F.1 Transmission Facilities at Manatee

The work required for the new capacity addition at Manatee, Manatee Unit No. 3, with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's, and one ST.
2. Construct two string busses to connect the collectors and main switchyard.
3. Add five main step-up transformers (4-225MVA, 1- 560MVA) one for each CT, and one for the ST.
4. Add two breakers in bay # 6 to connect the collector bus at the Manatee switchyard.
5. Add two breakers in bay # 5 at the Manatee switchyard to connect the other collector bus.
6. Add relays and other protective equipment.
7. Upgrade 13-230kV circuit breakers to 2 cycle Independent Pole breakers at Manatee switchyard.
8. Upgrade the existing line terminal at Johnson to 3000 Amps.
9. Expand site and relay vault for two new line terminals at Manatee switchyard.
10. Upgrade existing breaker at Ringling Sub to 3000 amps

II. Transmission:

1. Upgrade the Calusa-Charlotte 230kV transmission line to 1875 Amps.
2. Upgrade the Johnson- Manatee 230kV transmission line to 3000 Amps.
3. Upgrade the Manatee-Ringling # 3 230kV transmission line to 3000 Amps.
4. Upgrade the Charlotte-Fort Myers # 2 230kV transmission line to 1875 Amps.

III.F.2 Transmission Facilities at Martin

The work required for the incremental capacity planned to be added at Martin (convert the existing two CT's to a new four-on-one combined cycle unit, Martin Unit No. 8) with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing one collector buss with 3 breakers to connect the two CT's and one ST.
2. Add one station service transformer in the existing CT yard.
3. Add three main step-up transformers (2-225 MVA, 560 MVA) one for each CT, and one for the ST.
4. Add two breakers in bay # 3 to connect the collector bus in the main switchyard.
5. Add relays and other protective equipment.
6. Install phase reactors and string buss in main switchyard to limit fault current.
7. Add breaker in bay # 7 (7WE) for new Indiantown # 2 transmission line. Tap existing 69kV auto-transformer off east 230kV operating bus.
8. Add breaker in Bay # 3 (3WS) at Indiantown Substation for Bridge line.
9. Create new bay 4. Add breakers 4WM, 4WS for Indiantown-Martin #2 line at Indiantown Substation.
10. Create new bay # 1 at Bridge Substation with breakers 1WW and 1WM. Add breakers 2WW and 2WE to convert station configuration from ring buss to a breaker and a half scheme.
11. Construct one string bus to connect the collector and main switchyard.

II. Transmission:

1. Construct 230kV Martin-Indiantown # 2 transmission line.
2. Construct 230kV Indiantown – Bridge # 2 transmission line.
3. Various OHGW replacements due to increased fault current.
4. Upgrade the Ranch-Homeland 230kV transmission line to 1600 Amps.

III.F.3 Transmission Facilities at Turkey Point

The work required for the projected new CC unit at Turkey Point, Turkey Point Unit No. 5, with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's, and one ST.
2. Construct two string busses to connect the collector busses and main switchyard.
3. Add five main step-up transformers (4-225MVA, 1- 560 MVA) one for each CT, and one for the ST.
4. Add a new two breaker bay to connect the collector bus at the Turkey Point switchyard.
5. Add a second two breaker bay at the Turkey Point switchyard to connect the other collector bus.
6. Add relays and other protective equipment.
7. Expand site and relay vault for two new line terminals at Turkey Point switchyard.

II. Transmission:

1. Upgrade the Turkey Point-Galloway Tap 230kV transmission line section to 1418 Amps.
2. Upgrade the Turkey Point-McGregor-Florida City 230kV transmission line section to 1403 Amps.
3. Upgrade the Turkey Point-Miller 230kV transmission line section to 1356 Amps.
4. Upgrade the Miller-Killian 230kV transmission line section to 1315 Amps.

III.F.4 Transmission Facilities at Midway

The work required for the projected new CT units at Midway, Midway Unit Nos. 1A and 1B, with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing one collector buss with 2 breakers to connect the two CT's.
2. Construct one string buss to connect the collector buss and main switchyard.
3. Add two main step-up transformers (2-225 MVA) one for each CT.
4. Build a new 500 kV Bay #3 with two breakers and connect one string buss from the collector yard.
5. Add relays and other protective equipment.
6. Expand site and relay vault for the new line terminal at Midway 500 kV switchyard.

II. Transmission:

No upgrades are expected to be necessary.

III.F.5 Transmission Facilities at Corbett

The work required for the projected new CC unit at Corbett, Corbett Unit No. 1, with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's, and one ST.
2. Construct two string busses to connect the collector busses and main switchyard.
3. Add five main step-up transformers (4-225 MVA, 1- 560 MVA) one for each CT, and one for the ST.
4. Add a new Bay #4 with 3 breakers at the Corbett 230 kV main switchyard. Connect one string buss from the collector yard and relocate the Alva 230 kV terminal from Bay #3 to new Bay #4.
5. Connect second collector string buss to Bay #3.
6. Add relays and other protective equipment.
7. Expand site and relay vault for two new line terminals at Corbett 230 kV switchyard.

II. Transmission:

No upgrades are expected to be necessary.

III.G. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various technologies.

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970's in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FSEC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities on both a daily and annual basis in Florida. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-Kilowatt (KW) system was placed into operation in 1984. (After the testing of this PV installation was completed, the system was removed in 1990 to make room for substation expansion.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed on the following page).

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first and only large scale utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was not cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980's, FPL introduced another renewable energy program. FPL's Passive Home Program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for 6 passive homes with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test may be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

FPL then analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach did not require all of its customers to bear PV's high cost, but allows customers who are interested in facilitating the use of renewable energy the means to do so. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund that FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid. Thus, when sunlight is available, the PV-generated electricity displaces an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach, which was termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's initial efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995, and FPL received approval from the FPSC in 1997 to proceed. FPL initiated the effort in 1998 and received approximately $89,000 in contributions (that significantly exceeded the goal of $70,000). FPL used this money to purchase PV modules and installed them at FPL's Martin Plant site.

FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was the Green Energy Project, which is a second, different attempt to implement the basic Green Pricing approach. This outcome of this project was discussed in Section III.D.2.

The second effort initiated in 2000 was FPL's Photovoltaic Research, Development, and Education Project. This demonstration project's objectives are to increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks (as well as the total annual energy capabilities of roof tile PV systems), and assess the homeowner's financial benefits and costs of PV roof tile systems. The outcome of this effort is also discussed in section III.D.2.

Finally, FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy and as-available energy have been purchased by FPL from these developers. (Please refer to Tables I.B.1 and I.B.2).

III.H FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980's, FPL relied primarily on a combination of oil and nuclear energy to generate electricity. In the early 1980's FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). In 1991 FPL significantly expanded its natural gas firm transportation rights. In 1994 FPL re-powered its Lauderdale Units No. 4 and No. 5 to combined cycle and added Martin Units No. 3 and No. 4 to enhance the efficient utilization of natural gas. Additional coal resources were added with the partial acquisition of Scherer Unit No. 4 concluding with FPL owning 76% of the unit by 1995. Beginning in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP further diversifying the fuel mix. These steps, among others, allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. In addition, between 1994 and 1998 FPL actively sought certification to convert its Manatee Units No. 1 and No. 2 to utilize Orimulsion. The Governor and cabinet did not grant a certification for this conversion that would have further diversified FPL's fuel mix.

The trend in recent years has been a steady increase in the amount of natural gas that is used by FPL to provide electricity. This is driven by the application of combined cycle generating units that offer significant thermal efficiency, low emissions and low capital costs. Until recently, the price of natural gas was low enough that the economic analysis indicated combined cycle technology as the most cost-effective alternative. Although this planning document reflects a continuation of the trend of natural gas-fired additions, FPL's plan is subject to change as new fuel price forecasts are developed and FPL's knowledge of other cost drivers and uncertainties is refined. FPL's future resource planning work will continue to focus on identifying and evaluating alternatives that will maintain or enhance FPL's long-term fuel diversity. These fuel diversity-enhancing alternatives may include:

- the construction of new solid fuel-based (coal and petroleum coke) facilities
- obtaining access to diverse sources of natural gas, such as from suppliers of natural gas that transport and deliver natural gas to Florida in the form of LNG
- preserving FPL's ability to utilize fuel oil at its existing units.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2013 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2. For purposes of this fuel mix projection, it was conservatively assumed that the projected new purchases to replace the UPS capacity would be delivered from natural gas-fired units.

2. Fuel Price Forecasts

FPL's long-term oil price forecast assumes that worldwide demand for petroleum products will grow moderately throughout the planning horizon. Non-OPEC crude oil supply is projected to increase as new and improved drilling technology and seismic information will reduce the cost of producing crude oil and increase both recoveries from existing fields and new discoveries. However, the rate of increase in non-OPEC supply is projected to be slower than that of petroleum demand, resulting in an increase in OPEC's market share throughout the planning horizon. As OPEC gains market share, prices for petroleum products are projected to increase.

FPL's natural gas price forecast assumes that domestic demand for natural gas will grow throughout the planning horizon, primarily due to increased requirements for electric generation. Domestic natural gas production will increase as new and improved drilling technology and seismic information will reduce the cost of finding, developing, and producing natural gas fields. The rate of increase in domestic natural gas production is assumed to be slower than that of demand nationally, with the balance being supplied by increased Canadian and liquefied natural gas (LNG) imports. As demand for natural gas in Florida grows, it is anticipated that the Florida Gas Transmission (FGT) pipeline system will be augmented/expanded. This anticipated expansion of FGT's pipeline, combined with the new Gulfstream pipeline and potential sources of non-domestic/international natural gas (such as off-shore suppliers), should result in sufficient gas for FPL's continued needs.

FPL's coal price forecast assumes an ample supply of domestic coal, and the availability of imported coal, to meet a slow, but steady increase in domestic demand in the electric generation sector over the planning horizon. The coal price forecast for FPL's existing coal plant at St. Johns River Power Park (SJRPP) and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts, along with the purchase of spot coal, to meet generation requirements. FPL's petroleum coke price forecast assumes that the petroleum industry will continue to utilize cokers in the U.S., as well as in the Caribbean Basin, in order to maximize refinery production of light products. This trend will continue to result in sufficient availability of petroleum coke at delivered prices significantly below delivered coal prices that will support a slow, but steady growth in the use of petroleum coke in the U.S. electric utility industry.

As previously mentioned, FPL's resource planning work will continue to analyze the feasibility of generation alternatives, including solid fuel alternatives, that enhance FPL's long-term fuel diversity. The analyses of gas-fired and solid fuel-fired alternatives will involve the assessment of a number of uncertainties including fuel price uncertainties. Consequently, for these analyses a number of fuel price sensitivities will be used in the analyses that determine the magnitude and likelihood of cost differentials between gas and solid fuel alternatives.

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated. All values are Summer net MW.

2/ Total Capacity Available = Col.(2) + Col.(3) - Col.(4) + Col.(5).

3/ These forecasted values reflect the Most Likely forecast without DSM.

4/ The MW shown represent cumulative load management capability plus incremental conservation. They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based.

5/ Margin (%) Before Maintenance = Col.(10) / Col.(9)

6/ Margin (%) After Maintenance = Col.(13) / Col.(9)

The new Corbett CC unit does not require any "new" transmission lines.

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in FPL's service area is continuing, which increases competition for air, land, and water resources that are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among utilities for its commitment to the environment. FPL's environmental leadership has been heralded by many outside organizations. For example, FPL was recently ranked first out of 28 major electric utilities surveyed in an environmental assessment conducted by Innovest, an independent advisory group. In recognition of its success in executing a strategy to become a clean energy provider harnessing primarily clean and renewable fuels while also boosting shareholder value, FPL Group, Inc. was named in June 2003 as the winner of the Edison Award, the electric power industry's highest honor by the Edison Electric Institute. FPL was also awarded Edison Electric Institute's National Land Management Award for its stewardship of 25,000 acres surrounding the Turkey Point Plant. In addition, FPL won the Council for Sustainable Florida's award for its sea turtle conservation and education programs at the St. Lucie Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. FPL also received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida Department of Environmental Protection named FPL a "Partner for Ecosystem

Protection" for its emission-reducing "repowering" projects at the Fort Myers and Sanford Plants. In addition, FPL has been recognized by numerous federal and state agencies for its innovative endangered species programs which include such species as manatees, crocodiles, and sea turtles.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define the Company's position. This statement reflects how FPL incorporates environmental values into all aspects of the Company's activities and serves as a framework for new environmental initiatives throughout the Company. The FPL environmental statement further establishes a long-term direction of environmental initiatives throughout the Company. FPL's Environmental Statement is:

> It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:
>
> - Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
> - Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
> - Encourage the wise use of energy to minimize the impact on the environment.
> - Communicate effectively on environmental issues.
> - Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident/emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

In February 2004 FPL Group voluntarily committed to join the World Wildlife Fund PowerSwitch Challenge in support of binding limits on national CO2 emissions. This commitment was made to support initiatives to better manage utility impacts on global warming through use of greenhouse gas emission reductions and improvements in energy efficiency.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with Company policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to: facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and Company policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2003 environmental outreach activities are noted in Table IV.E.1.

Activity	# of Participants
Visitors to Energy Encounter	19,000
Visitors to Manatee Park	150,000
Number of "visits" to FPL's Environmental Website	185,000
Number of pieces of Environmental literature distributed	>100,000

Table IV.E.1

(All numbers are approximations.)

IV.F. Preferred Sites

FPL identifies three preferred sites in this Site Plan: the existing Manatee plant site, the existing Martin plant site, and the existing Turkey Point plant site. The Manatee and Martin sites are the locations for capacity additions that FPL is committed to bring in-service in 2005. The Turkey Point site is the location for FPL's planned new Turkey Point Unit No. 5 which is projected to come in-service in 2007.

The three preferred sites are discussed below.

Preferred Site # 1: Manatee Plant, Manatee County

The site is located in unincorporated north central Manatee County approximately 2.5 miles south of the Hillsborough-Manatee County line. It is 5 miles east of Parrish, Florida and is approximately 5 miles east of U.S. Highway 301 and 9.5 miles east of Interstate 75 (I-75). State Road (SR) 62 is about 0.5 miles south of the site. Saffold Road marks the eastern boundary of the site.

FPL's Manatee Plant occupies a portion of the approximately 9,500 acre Manatee Site which is owned wholly by FPL. The site includes a 4,000-acre cooling pond including the dike area. The existing approximately 1,630 MW (Summer) of generating capacity is made up of two steam units (Units No. 1 and No. 2) which have been in service since 1976 (Unit No. 1) and 1977 (Unit No. 2). These units burn both fuel oil (residual) with a maximum sulfur content of 1 percent and natural gas. Natural gas may be fired singly or in combination with fuel oil. A recent agreement between FPL and Gulfstream Natural Gas Systems (Gulfstream) will provide natural gas for these units.

Additional generating capacity will be added to the site in 2005 to meet projected FPL system capacity needs. One unit consisting of four new combustion turbines (CT's), four new heat recovery steam generators (HRSG's), and a new steam turbine generator are scheduled for in -service operation beginning in June, 2005. The four new CT's, HRSG's and steam turbine will ultimately be operating in combined cycle (CC) configuration. This new CC unit will add 1,107 MW (Summer) and 1,201 MW (Winter) capability to the site. This new CC Unit will be designated as "Manatee Unit No. 3".

Unit No. 3 will be located west of the existing generating Units No. 1 and No. 2. The location of the new combined cycle Unit No. 3 at the Manatee Plant site and the selection of the highly efficient combined cycle technology (firing clean natural gas) will maximize the beneficial use of the site while minimizing environmental and land use impacts otherwise associated with the development of a new generating plant of this capacity. The Manatee site has been listed as a preferred or potential site in previous FPL Site Plans.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the Manatee plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 4,000 acre cooling pond. Manatee Units No. 1 and No. 2 will not be affected by the addition of Unit No. 3. The area for Unit No. 3 is expected to comprise approximately 73 acres. The site and surrounding land uses are almost exclusively agriculture with the exception of the Willow Shores residential area located northwest of the Manatee Plant site. Individual homes are located in the larger of two out parcels within the Manatee Plant site along SR 62 at the northeast corner of the site. The vast majority of the Manatee Plant site has been redesignated from Agricultural/Rural to Major Public/Semi Public (1) (P/SP) land use category by the Manatee County Commission on November 19, 2002 with the approval of Ordinance 02-13. Electric generating plants are specifically allowed in the P/SP category in accordance with the Manatee County Local Government Comprehensive Plan and Land Development Regulation Act, Chapter 163, Part II, Florida Statutes (FS).

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

There are no incorporated areas within 5 miles of the Manatee Plant site. Unincorporated communities in the area include Willow, located about 2 miles north of the Manatee Plant; Parrish, located about 5 miles southwest of the plant; and, in Hillsborough County, Sundance, located 3 miles northwest of the plant; Sun City Center, located 7 miles north of the plant; and Wimauma, located 8 miles northeast of the plant.

The Manatee Plant site includes areas of improved pasture with forested land southeast of the project area. This forested area is comprised of flat woods and oak habitat. The western side of the Manatee Plant site is currently used for row crops (tomato farm). There are also wetlands to the southeast containing wet pine flat woods mixed with dry pine flat woods. There will not be any disturbance of existing wetlands associated with this project.

2. Listed Species

Construction and operation of the new Unit No. 3 at the site is not expected to affect any rare, endangered, or threatened species. The majority of the site is cleared, grassed, and periodically mowed. The project area has been significantly altered by the construction and operation of the existing plant facilities, and, as a result, wildlife utilization of this area is expected to be minimal. Common wading birds utilizing the plant site outside of the project area include the great blue heron, little blue heron, great egret, snowy egret, and the white ibis. Typical mammals found in the habitats surrounding the project area are common bobcat, raccoon, deer, feral hog, opossum, armadillo, skunk and gray squirrel. Avian species observed in the vicinity of the project include bald eagles, a variety of songbirds, red-shouldered hawks, and marsh hawks.

3. Natural Resources of Regional Significance Status

There are no county, state or federally designated areas located within one mile of the plant site. The construction and operation of Manatee Unit No. 3 is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands that are associated with the Little Manatee River within a 5-mile radius of the project site. These lands include: Little Manatee River State Recreation Area, Little Manatee River State Canoe Trail, Florida Gulf Coast Railroad Museum, Cockroach Bay Aquatic Preserve, Critical Manatee Habitat, South Hillsborough Wildlife Corridor, Hillsborough County ELAPP Parcels, and SOR-Little Manatee River.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option, Manatee Unit No. 3, is the addition of four new combustion turbines and HRSG's and one new steam turbine generator in combined cycle mode in a 4x1 configuration. Manatee Unit No. 3 is scheduled to begin operation in mid – 2005. Natural gas, delivered via pipeline, will be the sole fuel for this unit.

Mitigation options being planned for Manatee Unit No. 3 include the capture and reuse of plant process water and rainwater. In addition, other mitigating options include the use of combustion technology that is very efficient and low in air pollutant emissions, combined with pollution control technology (dry-low NO_x burners and selected catalytic reduction equipment).

g. Local Government Future Land Use Designations

As mentioned above, the Local Government Future Land Use Plan is consistent with the existing Designated uses of the Manatee Plant Site as major portions of the site are designated as Major Public/Semi Public (1) – P/PS/. Electric generating plants are specifically allowed in this land use category.

h. Site Selection Criteria and Process

The Manatee site has been selected as a preferred site due to consideration of various factors including system load and economics. Also, the at–the–time projected availability of a natural gas pipeline that will be available to Unit No. 3 (as well as Units No. 1 and No. 2) was also a major factor in the selection of the Manatee site for the new 4x1 CC unit. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues and the site is permitted.

i. Water Resources

The available surface water source is the Little Manatee River that supplies makeup water for the 4,000-acre cooling pond. Plant process and service water requirements are currently supplied by the cooling pond. There are three wells in the Floridan Aquifer that are reserved for standby purposes.

j. Geological Features of Site and Adjacent Areas

Manatee County has three physiographic provinces: the Gulf Coast Lowlands, the DeSoto Plains, and the Polk Upland. The Manatee Plant is situated on the boundary of the DeSoto Plains and the Gulf Coast Lowland provinces. The geology underlying the Manatee Plant consists of unconsolidated sediments comprised of sand, clay silt, marl shell, limestone, and phosphorite (terrace deposits) from the Pleistocene age to recent. Undifferentiated deposits comprised of sand and clay are generally described to be less than 25 feet thick. Underlying the differentiated materials are the Miocene Hawthorn Formation, the Tampa Member, the Suwanee Limestone of the Oligocene age, the Ocala Limestone of the Eocene Age, the Avon Park Formation, the Oldsmar Formation of the Eocene age, and the Cedar Key Formation of the Paleocene age.

The major hydro-geologic units that exist in the vicinity of the site include, in descending order: the surficial aquifer system, the intermediate aquifer system, and the Upper Floridian aquifer. The surficial aquifer system is generally unconfined in Manatee County and consists of Quaternary deposits of predominately marine and non-marine quartz sand, clayey sand, shell, shelly marl, phosphorite, and occasional marl stringers and limestone. In the vicinity of the site the surficial sediments are approximately 25 feet thick.

k. <u>Projected Water Quantities for Various Uses</u>

The estimated additional quantity for process water is estimated to be 150 gpm (gallons per minute). FPL operates on-site water treatment systems for this use. Water quantities for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l. <u>Water Supply Sources by Type</u>

Manatee Unit No. 3 will utilize the existing on-site cooling pond as its source of cooling water. The cooling pond operates as a "closed cycle" system; any makeup water is provided from the Little Manatee River to replace net evaporation and seepage losses from the pond. These makeup needs are within an agreement between FPL and the Southwest Florida Water Management District (SWFWMD). There are three wells currently on reserve (stand-by) that are in the Floridan Aquifer.

FPL is currently evaluating alternative water sources for use at the Manatee Plant site.

m. Water Conservation Strategies Under Consideration

Available water including non-contact storm water, treated industrial wastewater, treated sanitary wastewater, and recovered service water are captured and returned to the cooling pond. Storm water from the equipment areas is also treated and returned to the cooling pond.

n. Water Discharges and Pollution Control

The Manatee Plant utilizes a Best Management Practices (BMP) plan, Spill Prevention, Control, and Countermeasure (SPCC) plan to assist in the control of inadvertent release of pollutants. Storm water runoff will be collected and routed to detention ponds. Construction activities are managed so that equipment maintenance and fueling are performed in designated areas so that, in the event of a spill or release of any contaminant, impacts to any surface water or the cooling pond are minimized.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by fuel delivery services and facilities for residual, low sulfur (1 percent) fuel oil and, most recently, natural gas as an alternate fuel for existing Units No. 1 and No. 2. The Unit No. 3 addition will be solely fueled by natural gas that will be supplied by Gulfstream.

p. Air Emissions and Control Systems

The addition of natural gas as a permitted fuel for existing Units No. 1 and No. 2 is expected to lower overall emissions during periods when natural gas, instead of fuel oil, is used. In addition, a NO_x reduction technology, re-burn, has been approved for installation on Units No. 1 and No. 2 within the next several years.

The use of clean fuels and combustion controls will minimize air emissions from Unit No. 3 and ensure compliance with applicable emission limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of carbon monoxide and volatile organic compounds. NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). These design alternatives constitute the Best Available Control Technology (BACT) for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Manatee Unit # 3 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise would be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will also be within allowable levels.

r. Status of Applications

FPL filed the Site Certification Application (SCA) for the Manatee Plant Unit No. 3 with the Florida Department of Environmental Protection (FDEP) on February 20, 2002, and received approval and Site Certification by the Governor and Cabinet in April, 2003. FPL acquired all permits needed and commenced construction in May, 2003. Modifications to operating permits will be pursued as necessary through 2004.

Preferred Site # 2: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District (SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad. The Martin site was identified in 1987 as a preferred location for development of coal gasification/combined cycle electric generation facilities and subsequent FPL Site Plans have continued to identify this site as a preferred site.

The existing 2,906 MW (Summer) of generating capacity at FPL's Martin site occupies a portion of the approximately 11,300 acres that are wholly owned by FPL. The generating capacity is made up of two steam units (Units No. 1 and No. 2), plus two combined cycle units (Units No. 3 and No. 4), and two combustion turbine units (Units No. 8a and No. 8b). The site includes a 6,800-acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

Additional generating capacity was added to the site in 2001 in the form of two combustion turbines (CT's) that operate in simple cycle mode using natural gas. These two CT's will be converted into one four-on-one (4X1) combined cycle (CC) unit with the addition of two new CTs, four new Heat Recovery Steam Generators (HRSGs), and a new steam turbine generator. The resulting CC unit will be known as Martin Unit No. 8. It is estimated to be in service in mid-2005 adding approximately 785 MW of capacity.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the Martin plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres. To the east of the power plant there is an area of mixed pine flat wood with a scattering of small wetlands. To the north of the cooling pond there is a 1,200-acre area which has been set aside as a mitigation area. There is a peninsula of wetland forest on the West Side of the reservoir that is named the Barley Barber Swamp. The Barley Barber Swap encompasses 400 acres and is preserved as a natural area. There is also a 10-kilowatt (kW) photovoltaic energy facility at the south end of this site.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

As noted above, the Barley Barber Swamp is located on the site. There is also a 1,200-acre mitigation area in the northern area of the site where wetlands and uplands have been preserved. Along the south and west sides of the cooling pond is an area where the vegetation has been maintained in its natural state in order to serve as a wildlife corridor. There are pine flat woods and small-scattered wetlands to the east of the plant.

2. Listed Species

Construction and operation of a new unit at the site is not expected to affect any rare, endangered, or threatened species. There are two active Bald Eagle (*Haliaeetus leucocephalus*: Federal-and State-listed as Threatened) nests that have been on the site for many years. The Florida Natural Areas Inventory (FNAI) database notes a record of Eastern Indigo Snakes (*Drymachon coralis coupert*, which are Federal-and State listed as threatened) in the Barley Barber Swamp. A number of other Bald Eagle nests and sightings of Eastern Indigo Snakes are reported by the FNAI database within a two-mile radius of the site. Infrequent sightings of Florida Panther have been made in the vicinity of the site area.

3. Natural Resources of Regional Significance Status

The Treasure Coast Regional Planning Council lists the "FPL Preserve", including the Barley Barber Swamp, as a Significant Regional Facility.

Natural communities such as uplands and wetlands are also generically listed as Resources of Regional Significance.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to add two new CT's and four new HRSG's and a new steam turbine that, together with the two existing CT's, will comprise Martin Unit No. 8. This unit is scheduled to be in-service in mid-2005. Natural gas delivered via pipeline is the primary fuel type for this unit (with light oil serving as a backup fuel). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available. Mitigation options include the capture and reuse of plant process water and rainwater, plus the use of a cooling tower. The facility already encompasses several preserved areas where wildlife is abundant.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is "Public Utilities". Designations for the surrounding area are primarily "Agricultural". There are also limited areas of "Agricultural Ranchette", "Industrial", and a small "Commercial" area designation. To the southeast of the property, fronting on the St. Lucie Canal, is an area designated for "Public Conservation".

h. Site Selection Criteria and Process

The Martin plant has been selected as a preferred site due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues. This site is considered permittable.

i. Water Resources

Surface water resources currently used at the Martin facility include the cooling pond which takes its water from the St. Lucie canal. The available ground water resource is the surficial aquifer system which is used as a source of potable water and for service water for Units No. 1 and No. 2. Both of these sources are available for use with the site expansion.

j. Geological Features of Site and Adjacent Areas

FPL's Martin site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks, about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine bin origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The deepest formation in Martin County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Lake City formation. The published information on the sediments comprising the formations below the

Avon Park Limestone in western Martin County is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach Counties.

k. **Projected Water Quantities for Various Uses**

The estimated additional quantity of water required for process water is 150 gallons per minute (gpm). FPL operates on-site water treatment systems for this use. Cooling water for new Unit No. 8 will be cycled through new cooling towers and approximately 7 million gallons per day for makeup water to the cooling tower will be needed. (The two existing CT's that will be converted into combined cycle operation are currently air-cooled.) Makeup water for the cooling pond is taken from the St. Lucie canal. The current makeup water quantity to the cooling pond is adequate for Unit No. 8.

l. **Water Supply Sources by Type**

Martin Unit No. 8 will utilize the existing on-site cooling pond as the source of makeup water for the cooling towers. Makeup water to the pond is withdrawn from the St. Lucie canal as needed to replace net evaporation and seepage losses from the pond. Such needs will comply with the existing agreement between FPL and the SFWMD regarding allocation of cooling water to the pond and with SFWMD's regulations for consumptive water use.

The existing water treatment system at the plant, which provides treated water for use in the Unit No. 1 and No. 2 boilers, as well as for the HRSG's associated with Units No. 3 and No. 4, will be used to provide treated water for Unit No. 8.

m. **Water Conservation Strategies Under Consideration**

The entire plant site captures and reuses process water whenever feasible and manages storm-water in such a manner so as to recharge the surficial aquifer.

n. **Water Discharges and Pollution Control**

Water discharges from the facility are minimized by collecting and treating most point sources into the existing cooling pond. Discharges from the cooling pond are infrequent and only occur for the protection of the cooling pond embankment. Collected sources of water include equipment wash water, boiler blowdown water, and equipment area runoff. Non-contact storm water runoff is collected and treated via a storm water management system. Design elements have been included to capture suspended sediments. Facility permits mandate various sampling and testing activities that provide indications of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. **Fuel Delivery, Storage, Waste Disposal, and Pollution Control**

The site is already serviced by multiple fuel delivery facilities. Three pipelines will serve the site. One pipeline is the FPL-owned north lateral from Florida Gas Transmission (FGT). A second pipeline is the FPL-owned south lateral dual purpose (oil and gas) pipeline which supplies oil to the steam boilers from the oil terminal on 45th Street and is interconnected with FGT. The third pipeline is a Gulfstream-owned lateral that will be constructed as part of the Unit No. 8 Conversion Project. Distillate fuel oil is received by truck and stored in above ground storage tanks. An additional above ground storage tank is being constructed to serve Unit No. 8.

p. **Air Emissions and Control Systems**

The use of clean fuels and combustion controls will minimize air emissions from Unit No. 8 and ensure compliance with applicable emission limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of carbon monoxide and volatile organic compounds. NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). These design alternatives constitute the BACT for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Martin Unit # 8 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. **Noise Emissions and Control Systems**

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise would be within allowable levels. Noise from the operation of the new unit will also be within allowable levels.

r. **Status of Applications**

A Site Certification Application (SCA) was filed in December, 1989 for the construction and operation of the Martin Coal Gasification/Combined Cycle project under the Florida Electrical Power Plant Siting Act. In 2000, FPL added two CT's operating in simple cycle mode via an amendment to the initial certification to the site. Now, in order to convert the two CT's from simple cycle to 4X1 CC configuration (Unit No. 8), a modification to the Site Certification was required. FPL filed the modification on February 1, 2002 with the Florida Department of Environmental Protection

(FDEP). Approval and Site Certification was issued by the Governor and Cabinet in April, 2003. FPL acquired all construction permits and commenced construction in May, 2003. Modifications to operating permits will be pursued as necessary. Unit No. 8 will be in-service by June, 2005.

Preferred Site # 3: Turkey Point Plant, Miami-Dade County

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear and two conventional fossil fuel boiler units and the cooling canals. Adjacent to the plant site is an FPL-owned and operated mitigation bank known as the Everglades Mitigation Bank (EMB) covering approximately 13,000 acres.

Existing Units No. 1 and No. 2 are fossil fuel generating plants with approximate generating capacity of 400 MW each. Unit No. 1 was completed in 1967 and Unit No. 2 in 1968. Existing Units No. 3 and No. 4 are nuclear generating units with approximate generating capacity of 690 MW each. Unit No. 3 was completed in 1972 and Unit No. 4 in 1973. Turkey Point also has five diesel peaking units that in total produce approximately 12 MW. These units are primarily used to provide emergency power, but occasionally run during the summer to provide power during peak load demands.

The proposed Expansion Site for the location of new Turkey Point Unit No. 5, a 4x1 CC unit, is within the existing FPL Turkey Point facility property. The Expansion Site is adjacent to the existing fossil Units No. 1 and No. 2, and includes the existing parking lot and storage areas immediately northwest of Units No. 1 and No. 2 as well as wetlands north of the facility.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the Turkey Point plant site, plus a map of the general layout of the proposed generating facilities at the site, is found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a self-contained cooling canal system that supplies water to condense steam used by the existing units' turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide and four feet deep. The remaining developed area of the site is where the two fossil steam generating units and 5 diesel generators are located. South of and adjacent to the fossil plant are the two nuclear generating units. Further to the south exists the EMB previously discussed.

e. General Environment Features On and In the Site Vicinity

1. Natural Environment

The majority of the proposed Expansion Site is undeveloped dwarf red mangrove swamp, tidally inundated with waters from Biscayne Bay. Along with the dominant red mangroves, buttonwood is a common canopy component, along with occasional white mangrove. Only a few individual black mangroves were observed within the Site. Biscayne Bay is a shallow, subtropical bay supporting sea grasses, sponges, coral reefs, and a variety of marine life.

2. Listed Species

The construction and operation of Unit No.5 is not expected to adversely affect any rare, endangered, or threatened species. One species listed by the FFWCC as a species of special concern was observed on the Expansion Site, the white ibis (Eudocimus albus). Listed species known to occur in the nearby Biscayne National Park that could potentially utilize the Expansion Site include the peregrine falcon (Falco peregrinus), wood stork (Mycteria americana), American crocodile (Crocodylus acutus), mangrove rivulus (Rivulus marmoratus), roseate spoonbill (Ajaja ajaja), limpkin (Aramus guarauna), little blue heron (Egretta caerulea), snowy egret (Egretta thula), American oystercatcher (Haematopus palliates), least tern (Sterna antillarum), brown pelican (Pelicanus occidentalis), and bald eagle (Haliaeetus leucocephalus). The FFWCC's bald eagle nest locator database was queried and resulted in no known nests in the vicinity of the Expansion Site. The federally listed, endangered American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the proposed Expansion Site. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American crocodile. A Project-specific crocodile management plan has been developed for construction of Unit No. 5.

3. Natural Resources of Regional Significance Status

Significant features in the vicinity of the proposed Expansion Site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. Biscayne National Park contains 180,000 acres, approximately 95% of which is open water interspersed with over 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant, adjacent to the Miami-Dade County Homestead Bayfront Park, which contains a marina and day use recreational facilities.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

The design option is to add one new unit consisting of four new CT's and four new HRSG's and a new steam turbine that will comprise Turkey Point Unit No. 5. This unit is scheduled to be in-service in mid-2007. Natural gas delivered via pipeline is the primary fuel type for this unit (with ultra low sulfur light oil serving as a backup fuel). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation options for unavoidable wetland impacts related to construction of Unit No. 5 that are being considered include on site hydrologic improvements to enhance existing wetlands, restoration and preservation of areas overgrown with exotic plant species, the purchase of mitigation credits from the EMB which is in the same drainage basin, and land preservation. Additional mitigating options include the capture and reuse of plant process water and rainwater, plus the use of cooling towers. The facility already encompasses several preserved areas where wildlife is abundant.

g. Local Government Future Land Use Designations

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. Site Selection Criteria and Process

For the past several years, a number of FPL's existing power plant sites have been considered as potentially suitable sites for new or re-powered generation. The Turkey Point plant has been selected as a preferred site due to consideration of various factors including system load, imbalances between load and generation in Southeast Florida, and economics. Recognizing that this site represents valued and sensitive environmental resources. FPL will give significant attention to minimizing environmental impacts and mitigating where impacts are unavoidable. This site is considered permittable.

i. Water Resources

Unique to Turkey Point Plant is the cooling canal system that supplies water to condense steam used by the plant's turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide and four feet deep. Water circulates through the 153-mile maze of canals in a two-day cycle, ending at the plant's intake pumps and cooling by as much as 15 degrees F.

However, FPL anticipates using a closed cooling system (cooling tower) for the new Unit No. 5 that uses forced air to cool the warm water coming off the generating equipment.

j. Geological Features of Site and Adjacent Areas

FPL's Turkey Point site is underlain by approximately 13,000 feet of sedimentary rock strata that forms the Biscayne aquifer. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily of marine origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The Tamiami formation is named for deposits composed principally of white cream-colored calcareous sandstone, sandy limestone, and beds and pockets of quartz sand. Key Largo limestone is present in the Turkey Point area.

The Floridan aquifer, located approximately 1,200 feet below the land surface, is a confined aquifer. The Floridan aquifer system is composed entirely of carbonate rocks, except for minor evaporates. The water in the carbonate rock aquifer is more highly mineralized.

k. Projected Water Quantities for Various Uses

The additional quantity of process water is estimated to average 150 gpm. Water for this use would be supplied by a county water system. Cooling water for new Unit No. 5 will be cycled through a new cooling tower and approximately 12 million gallons per day for makeup water to the cooling tower will be needed. FPL proposes to use water from the Floridan Aquifer as the source of make-up water used by the cooling towers.

l. Water Supply Sources by Type

Turkey Point Unit No. 5 will utilize the cooling towers for the dissipation of heat from the cooling water. A new water treatment plant, separate from the existing water treatment system that provides treated water for use in the boilers of Unit No. 1 and No. 2, will be constructed for Unit No. 5.

m. Water Conservation Strategies Under Consideration

A plan to treat and recycle equipment wash water, boiler blowdown, and equipment area runoff for use as service water would reduce ground water consumption.

n. **Water Discharges and Pollution Control**

Water discharges from the new unit will be minimized by collecting and treating most point sources, with the water eventually entering the existing cooling canal system. There are no surface water discharges from the cooling canal system. Collected sources of water include equipment wash water, boiler blowdown water, equipment area runoff, and storm water runoff.

Design elements have been included to capture suspended sediments. Various facility permits mandate various sampling and testing activities, which provide indication of any pollutant discharges.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. **Fuel Delivery, Storage, Waste Disposal, and Pollution Control**

The site is already serviced by multiple fuel delivery facilities. There is currently a pipeline that supplies natural gas to the facility. The facility also has oil capabilities through on-site storage tanks and accessibility to barge deliveries. The additional capacity will utilize the existing pipeline with the possible addition of compression system(s). An above ground storage tank for the ultra-low sulfur back-up fuel will be added.

p. Air Emissions and Control Systems

The use of clean fuels and combustion controls will minimize air emissions from the new unit and ensure compliance with applicable emission-limiting standards. Using clean fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter and other fuel bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NO_x emissions during CC operations when firing ultra-low sulfur backup fuel. These design alternatives constitute the BACT for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of Turkey Point Unit No. 5 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise expected to be caused by unit construction at the site is expected to be within allowable limits. Noise from the operation of the new unit will also be within allowable levels.

r. Status of Applications

FPL filed the SCA for the Turkey Point Plant Unit No. 5 with the Florida Department of Environmental Protection (FDEP) on November 14, 2003. A federal Dredge and Fill application was submitted to the U.S. Army Corps of Engineers on November 14, 2003. The certification process and the dredge and fill permit process is expected to be completed with final review by the Governor and Cabinet in January, 2005.

Construction would commence in spring 2005 with an anticipated, in-service date of mid-2007.

IV.G. Potential Sites for Gas-Fired Generating Options

Six (6) sites are currently identified as potential sites for near-term (primarily 2008-2010) future gas-fired generation additions to meet FPL's capacity needs.[2] These sites have been identified as "potential sites" due to considerations of location to FPL load centers, space, infrastructure, and/or accessibility to fuel and transmission facilities. These sites are suitable for different capacity levels and technologies.

Each of these potential sites offers advantages and disadvantages relative to engineering considerations and/or costs associated with the construction and operation of feasible technologies. In addition, each potential site has different characteristics that could require further definition and attention. For purposes of estimating water usage amounts, it is assumed that a natural gas-fired CC unit would be the technology of choice for any capacity additions at the sites.

Permits are presently considered to be obtainable for all of these sites, assuming measures can be taken to mitigate any particular site-specific environmental concerns that may arise. No significant environmental constraints are currently known for any of these six sites. The potential sites briefly discussed below are presented in alphabetical order. At this time FPL considers each site to be equally viable.

[2] As has been described in previous FPL Site Plans, FPL also considers a number of other sites as possible sites for future generation additions. These include the remainder of FPL's existing generation sites.

Potential Site # 1: Andytown Substation , Broward County

FPL has identified the Andytown Substation Property in western Broward County as a potential site for the addition of new generating capacity. Current facilities on-site include an electric substation. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Andytown site is provided at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land uses for the potential site are designated as industrial or agricultural use. The site identification process included screening of potential sites to determine potential wetland impacts and impacts to endangered or threatened species. Extensive low-quality wetlands are adjacent to the site. FPL would expect to mitigate any impacts from construction of a power plant at this site. Construction and operation of a new facility on this site is not expected to adversely affect any rare, endangered, or threatened species.

d. and e. Water Quantities and Supply Sources

Surface water sources are not available at the site identified for the new plant. Groundwater from the shallow aquifer, or a local source of gray water, has been identified as potential water sources. FPL estimates that up to 12 million gallons per day of industrial processing water would be required for uses such as boiler makeup,

cooling water makeup, pollution control device usage, inlet air-cooling and service water.

Potential Site # 2: Cape Canaveral Plant, Brevard County

This site is located on the FPL Cape Canaveral Plant property in unincorporated Brevard County. The city of Port St. Johns is located less than a mile away. The site has direct access to a four-lane highway (US 1). A rail line is located near the plant. The existing facility consists of two 400 MW (approximate) steam boiler type generating units.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Cape Canaveral property site is provided at the end of this chapter.

b. and c. Land Uses and Environmental Features

This site is located on the Indian River. The land is primarily dedicated to industrial use with surrounding grassy areas and a few acres of remnant pine forest. The land adjacent to the site is dedicated to light commercial and residential use. There are no significant environmental features on the site.

d. and e. Water Quantities and Supply Sources

Water sources available at the site include surface water and groundwater. Groundwater from the shallow aquifer, or surface water, has been identified as potential water sources. FPL estimates that up to 12 million gallons per day of industrial processing water would be required for uses such as boiler makeup,

cooling water makeup, pollution control device usage, inlet air-cooling and service water.

Potential Site # 3: Corbett Substation Property, Palm Beach County

FPL has identified the Corbett Substation Property in Western Palm Beach County as a potential site for the addition of new generating capacity. The existing site is an area accessible to both natural gas and electrical transmission through existing structures or through additional lateral connections.

a. U.S. Geological Survey (USGS) Map

A USGS map Corbett site is provided at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land uses for the potential sites are designated as industrial or agricultural use. The site identification process included screening of potential sites to determine potential wetland impacts and impacts to endangered or threatened species. Construction and operation of a new facility on these sites is not expected to adversely affect any rare, endangered, or threatened species.

d. and e. Water Quantities and Supply Sources

Water sources available at the site include surface water and groundwater. Groundwater from the Floridan aquifer, or surface water, has been identified as potential water sources. FPL estimates that up to 12 million gallons per day of industrial processing water would be required for uses such as boiler makeup,

cooling water makeup, pollution control device usage, inlet air-cooling and service water.

Potential Site # 4: Midway Substation Property, St. Lucie County

The site is located on the 122-acre Midway Substation property. Current facilities on the site include an electric substation. The site has direct access to a two-lane highway, State Road (SR) 712 and a nearby entrance to I-95. The City of Port St. Lucie is immediately east and west of the Midway site. The City of Ft. Pierce is approximately 9 miles northeast of the site.

a. U.S. Geological Survey (USGS) Map

A USGS map is provided of the Midway site area is provided at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is currently dedicated to industrial and agricultural use. Much of the site is currently not being used. Developed portions of the adjacent properties are primarily agricultural (orange groves and cattle grazing). Undeveloped portions include mixed scrub with some hardwoods and wetlands.

d. and e. Water Quantities and Supply Sources

Water sources available at the site include surface water and groundwater. Groundwater from the Floridan aquifer, or surface water, has been identified as potential water sources. FPL estimates that up to 12 million gallons per day of industrial processing water would be required for uses such as boiler makeup,

cooling water makeup, pollution control device usage, inlet air-cooling and service water.

Potential Site # 5: Port Everglades Plant, Broward County

This site is located on the 94-acre FPL Port Everglades plant site in Port Everglades, Broward County. The site has convenient access to State Road (SR) 84 and Interstate 595. A rail line is located near the plant. The existing plant consists of four steam boiler generating units: two 200 MW (approximate) and two 400 MW (approximate) sized units. The four steam boilers are capable of firing residual fuel oil, natural gas, or a combination of both. The site also is home to twelve simple cycle gas turbine (GT) peaking units of 30 MW (approximate) each. The GT's are part of the Gas Turbine Power Park that is made up of 24 GT's at the Lauderdale Plant site and the twelve GTs at the Port Everglades site. The GT's are capable of firing either natural gas or liquid fuel.

a. U.S. Geological Survey (USGS) Map

A map of the Port Everglades plant site is provided at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on this site is primarily industrial. The adjacent land uses are port facilities and associated industrial activities, oil storage, cruise ships, and light commercial.

d. and e. Water Resources and Supply Sources

Water sources available at the site include surface water and groundwater. Groundwater from the Floridan aquifer, or surface water, has been identified as potential water sources. FPL estimates that up to 12 million gallons per day of industrial processing water would be required for uses such as boiler makeup, cooling water makeup, pollution control device usage, inlet air-cooling and service water.

Potential Site # 6: Riviera Plant, Palm Beach County

This site is located on the FPL Riviera Plant property in Riviera Beach, Palm Beach County. The site has direct access to a four-lane highway, US 1, and barge access is available. A rail line is located near the plant. The facility currently houses two operational 300 MW (approximate) steam boiler generating units and two retired generating units.

a. U.S. Geological Survey (USGS) Map

A USGS map of the Riviera plant site is provided at the end of this chapter.

b. and c. Land Uses and Environmental Features

The land on the site is primarily covered by the existing generation facilities with some open maintained grass areas. There is a small manatee viewing area on the site which is operated seasonally by FPL. Adjacent land uses include port facilities and associated industrial activities, as well as light commercial and residential development. The site is located on the Inter-coastal Waterway near the Lake Worth Inlet.

d. and e. Water Quantities and Supply Sources

Water sources available at the site include surface water and groundwater. Groundwater from the Floridan aquifer, or surface water, has been identified as potential water sources. FPL estimates that up to 12 million gallons per day of industrial processing water would be required for uses such as boiler makeup, cooling water makeup, pollution control device usage, inlet air-cooling and service water.

IV.H. Potential Sites for Solid Fuel-Fired Generating Options

As previously discussed, FPL is currently in the process of analyzing the feasibility of solid fuel-based generating options. FPL believes that the earliest a solid fuel generating option could be permitted and constructed is 2011. At the time this document was being prepared, FPL had made no decision regarding these options for 2011 – and is continuing to analyze these options.

These analyses include on-going investigations of potential sites for solid fuel options. A number of potential sites for solid fuel-based generation are being studied including sites both in and outside of Florida. The potential Florida sites are generally outside of the southeast Florida region previously discussed due to permitting and fuel transportation considerations. FPL will provide specific information regarding sites in future Site Plans if solid fuel generation options are determined to be viable options.

CHAPTER V

Other Planning Assumptions & Information

(This page is left intentionally blank.)

Introduction

The Florida Public Service Commission (FPSC), in Docket No. 960111-EU, specified certain information that was to be included in an electric utility's Ten-Year Power Plant Site Plan filing. Among this specified information was a group of 12 items listed under a heading entitled "Other Planning Assumptions and Information". These 12 items basically concern specific aspects of a utility's resource planning work. The FPSC requested a discussion or a description of each of these items.

These 12 items are addressed individually below as separate "Discussion Items".

Discussion Item # 1: Describe how any transmission constraints were modeled and explain the impacts on the plan. Discuss any plans for alleviating any transmission constraints.

FPL's resource planning work considers two types of transmission constraints. External constraints deal with FPL's ties to its neighboring systems. Internal constraints deal with the flow of electricity within the FPL system.

The external constraints influence the development of assumptions regarding the amount of external assistance which is available and the amount and price of economy energy purchases. Therefore, these external constraints are incorporated both in the reliability analysis and economic analysis aspects of resource planning. The amount of external assistance which is assumed to be available is based on the projected transfer capability to FPL from outside its system as well as historical levels of available assistance. In its reliability analyses, FPL models this amount of external assistance as an additional generator within FPL's system which provides capacity in all but the peak load months. The assumed amount and price of economy energy are based on historical values and projections from production costing models.

Internal transmission constraints or limitations are addressed by identifying potential geographic locations for potential new units that may not adversely impact, or that may even alleviate, such constraints and limitations and in developing the costs for siting new units, or delivering power from existing units, at different locations. Both site- and system-related transmission costs are developed for each different unit/unit location option or groups of options.

FPL's annual transmission planning work determines transmission additions needed to address constraints and to maintain/enhance system reliability. FPL's transmission plans are presented in Section III.E.

Discussion Item # 2: Discuss the extent to which the overall economics of the plan were analyzed. Discuss how the plan is determined to be cost-effective. Discuss any changes in the generation expansion plan as a result of sensitivity tests to the base case load forecast.

As discussed in Chapter III of this document, FPL typically performs economic analyses of competing resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI) and Stone and Webster Management Consultants, Inc. The resource plan reflected in this document emerged as the resource plan with the least impact on FPL's levelized system average electric rates (i.e., a Rate Impact Measure or RIM approach) and on the present value of revenue requirements for the FPL system.[3]

No sensitivity case analyses based on different load forecasts were carried out during FPL's most recent planning work. This is due to the fact that the near-term options projected to be added are combustion turbines can be added to the system on relatively short notice. If higher–than–projected loads begin to appear, combustion turbines can be placed in service in simple cycle mode in response to this unexpected occurrence. FPL believes that this fact qualitatively enables it to be able to address higher–than–projected loads.

[3] FPL's basic approach in its resource planning work is to base decisions on a lowest electric rate basis. However, when DSM levels are considered a "given" in the analysis, the lowest rate basis and the lowest system revenue requirements basis are identical. In such cases (as in FPL's current resource planning work), FPL evaluates options on the simpler – to – calculate (but equivalent) lowest system revenue requirements basis.

Discussion Item # 3: Explain and discuss the assumptions used to derive the base case fuel forecast. Explain the extent to which the utility tested the sensitivity of the base case plan to high and low fuel price scenarios. If high and low fuel price sensitivities were performed, explain the changes made to the base case fuel price forecast to generate the sensitivities. If high and low fuel price scenarios were performed as part of the planning process, discuss the resulting changes, if any, in the generation expansion plan under the high and low fuel price scenario. If high and low fuel price sensitivities were not evaluated, describe how the base case plan is tested for sensitivity to varying fuel prices.

The basic assumptions FPL used in deriving its base case or "Most Likely" fuel price forecast are discussed in Chapter III of this document.

In its most recent planning work, FPL did not test the sensitivity of its resource plan to fuel price forecasts different than its "Most Likely" fuel price forecast. All of the options considered in the IRP analysis for possible near-term implementation (i.e., through at least 2010) were natural gas-fired units, so any change in the fuel costs projections would have affected these near-term options in essentially the same way. Consequently, FPL concluded that a fuel price sensitivity case would not have provided information that would affect the selection of resources in the plan.

This approach is unique to the specific resources identified in this plan. FPL's on-going resource planning work will analyze the potential for solid fuel alternatives for the 2011-on time period. Support of these analyses will likely include fuel price sensitivity considerations to identify both the magnitude and likelihood of fuel cost reductions or the ability of fuel diversification to reduce the volatility of FPL's system fuel costs.

Discussion Item # 4: Describe how the sensitivity of the plan was tested with respect to holding the differential between oil/gas and coal constant over the planning horizon.

For the same reason given in response to Discussion Item #3, FPL did not conduct a "constant fuel differential" sensitivity analysis in its most recent planning work.

Discussion Item # 5: Describe how generating unit performance was modeled in the planning process.

The performance of existing generating units on FPL's system was modeled using current projections for scheduled outages, unplanned outages, and capacity output ratings and heat rate information. Schedule 1 and Schedule 8 present the current and projected capacity output ratings of FPL's existing units. The values used for outages and heat rates are generally consistent with the values FPL has used in planning studies in recent years.

In regard to new unit performance, FPL utilized current projections for the capital costs, fixed and variable operating & maintenance costs, capital replacement costs, construction schedules, heat rates, and capacity ratings for all construction options which were considered in the resource planning work. A summary of this information for the new capacity options FPL projects to add over the planning horizon is presented on the Schedule 9 forms.

Discussion Item # 6: Describe and discuss the financial assumptions used in the planning process. Discuss how the sensitivity of the plan was tested with respect to varying financial assumptions.

The key financial assumptions used in FPL's most recent resource planning work were 45% debt and 55% equity FPL capital structure, projected debt cost of 6.4%, and an equity return of 11.0%. These assumptions resulted in a weighted average cost of capital of 8.9% and an after-tax discount rate of 7.8%. In its recent planning work, FPL did not test the sensitivity of its resource plan to varying financial assumptions. The reason for this is that FPL's planning work focused on near-term FPL construction options only that were generally very similar in design and varied only by site. Consequently, FPL concluded that varying financial assumptions would have resulted in no significant change in the results of the analysis.

Discussion Item # 7: Describe in detail the electric utility's Integrated Resource Planning process. Discuss whether the optimization was based on revenue requirements, rates, or total resource cost.

FPL's integrated resource planning (IRP) process is described in detail in Chapter III of this document.

The standard basis for comparing the economics of competing resource plans in FPL's basic IRP process is the impact of the plans on FPL's electricity rate levels with the intent of minimizing FPL's levelized system average rate (i.e., a Rate Impact Measure or RIM approach). However, in its most recent planning work FPL utilized a net present value of system revenue requirements as the basis for comparing resource plans. (As discussed in response to Discussion Item # 2, both the electricity rate basis and the system revenue requirement basis are identical when DSM levels are unchanged between competing plans. Such was the case in FPL's recent planning work.)

Discussion Item # 8: Define and discuss the electric utility's generation and transmission reliability criteria.

FPL uses two generation reliability criteria in its resource planning work. One of these is a minimum 20% Summer and Winter reserve margin for the mid – 2004 – on time period. The other reliability criterion is a maximum of 0.1 days per year loss-of-load-probability (LOLP). These reliability criteria are discussed in Chapter III of this document.

In regard to transmission reliability, FPL has adopted transmission planning criteria that are consistent with the planning criteria established by the Florida Reliability Coordinating Council (FRCC). The FRCC has adopted transmission planning criteria that are consistent with the planning criteria established by the North American Electric Reliability Council (NERC) in its *Planning Standards*. FPL has applied these planning criteria in a manner consistent with prudent utility practice. The *NERC Planning Standards* are available on the internet (http://www.nerc.com/~filez/pss-psg.html).

In addition, FPL has developed a Facility Connection Requirements (FCR) document as well as a Facility Rating Methodology document that are also available on the internet (http://www.floasis.siemens-asp.com/oasis/fpl/info.htm). Thermal ratings for specific transmission lines or transformers are found in load flow cases.

Generally, the normal voltage criteria for FPL stations is given below:

Voltage Level (kV)	Vmin (p.u.)	Vmax (p.u.)
69, 115, 138	0.95	1.05
230	0.95	1.06
500	0.95	1.07

There may have been isolated cases for which FPL may have determined it prudent to deviate from the general criteria stated above. The overall potential impact on customers, the probability of an outage actually occurring, as well as other factors, may have influenced the decision in such cases.

Discussion Item # 9: Discuss how the electric utility verifies the durability of energy savings for its DSM programs.

The impact of FPL's DSM Programs on demand and energy consumption is revised periodically. Engineering models, calibrated with field-metered data, are updated when significant efficiency changes occur in the marketplace. Participation trends are tracked for all of the FPL programs in order to adjust impacts each year for changes in the mix of efficiency measures being installed by program participants.

Survey data is collected from non-participants in order to establish the baseline efficiency. Participant data is compared against non-participant data to establish the demand and energy saving benefits of the utility program versus what would be installed in the absence of the program. Finally, FPL is careful to claim only program savings for the average life of the installed efficiency measure. For these DSM measures which involve the utilization of load management, FPL conducts periodic tests of the load control equipment to ensure that it is functioning correctly.

Discussion Item # 10: Discuss how strategic concerns are incorporated in the planning process.

Among the strategic or non-price factors FPL typically considers when choosing between resource options are the following: (1) fuel diversity; (2) technology risk; and (3) environmental risk.

Fuel diversity relates to two concepts, the diversity of sources of fuel (e.g., coal vs. oil vs. natural gas), and the diversity of supply for a single fuel source (for example alternative pipeline suppliers for natural gas). All other factors being equal, supply options that increase diversity in fuel source and/or supply would be favored over those that do not.

Technology risk is an assessment of the relative maturity of competing technologies, For example, a prototype technology which has not achieved general commercial acceptance has a higher risk than a technology in wide use and, therefore, is less desirable.

Environmental risk is an assessment of the relative environmental acceptability of competing technologies. Technologies which might be regarded as more acceptable from an environmental perspective (e.g., natural gas-fired options) might be considered more favorably.

All of these factors play a part in FPL's planning and decisions, including its decisions to construct capacity or to purchase power.

Discussion Item # 11: Describe the procurement process the electric utility intends to utilize to acquire the additional supply-side resources identified in the electric utility's ten-year site plan.

As has been previously discussed, the very near–term elements of FPL's capacity additions include a number of firm capacity short-term purchases and the construction (or proposed construction) of three new generating units; one each at FPL's existing Martin, Manatee and Turkey Point sites. The firm capacity short-term purchases were acquired through negotiations and the three generation construction projects were selected after evaluating competing proposals received in response to Request for Proposals (RFP's) issued by FPL in mid-2002 and mid-2003 respectively. The decision to construct new combined cycle units at FPL's existing Martin and Manatee sites was subsequently approved by the Florida Public Service Commission (FPSC) in late 2002. FPL has recently filed for FPSC approval of the Turkey Point combined cycle unit and expects a decision later this year.

FPL's current plan reflects the addition of two CT's to meet the 2008 need. This part of the plan will be refined after DSM goals are approved in the 3rd or 4th Quarter of 2004. FPL will also continue to evaluate purchases from existing units to meet all or part of the 2008 need.

To the extent that the capacity additions for 2009 and beyond require approval under the Power Plant Siting Act, FPL would conduct a capacity solicitation process similar to these Request for Proposal (RFP) processes.

FPL's current plan includes purchases to replace the UPS contracts that expire 2010. At present FPL is evaluating various purchase strategies for filing this need.

Discussion Item # 12: Provide the transmission construction and upgrade plans for electric utility system lines that must be certified under the Transmission Line Siting Act (403.52 – 403.536, F. S.) during the planning horizon. Also, provide the rationale for any new line.

FPL plans to construct a new transmission line (by December 2005) that is presently being certified under the Transmission Line Siting Act (403.52 – 403.536, F.S.). The new line will connect FPL's Orange River Substation to FPL's Collier Substation (as shown on Table III.F.1). The certification process for this new line should be completed by the summer of 2004. The construction of this line is necessary to serve existing and future customers in the Collier and Lee areas in a reliable and effective manner. Additionally, FPL has identified the need for a new 230kV transmission line (by June 2008) that requires certification under the Transmission Line Siting Act (403.52 – 403.536, F.S.). The new line will connect FPL's St. Johns Substation to FPL's proposed West Palm Coast Substation (as shown on Table III.F.1). The construction of this line is necessary to serve existing and future customers in the Flagler and St. Johns areas in a reliable and effective manner.

Overview of the Document

Chapter 186, Florida Statutes, requires that each electric utility in the state of Florida with a minimum existing generating capacity of 250 megawatts (MW) must annually submit a Ten-Year Power Plant Site Plan. This plan includes an estimate of the utility's electric power generating needs, a projection of how those needs will be met, and a disclosure of information pertaining to the utility's preferred and potential power plant sites. This information is compiled and presented in accordance with Rules 25-22.070, 25-22.071, and 25-22.072, Florida Administrative Code (FAC).

This Ten-Year Power Plant Site Plan (Site Plan) document is based on Florida Power & Light Company's (FPL) planning analyses that were carried out in 2004 and that were completed in the first quarter of 2005. The forecasted information presented in this plan addresses the 2005–2014 time period.

Site Plans are long-term planning documents and should be viewed in this context. A Site Plan contains tentative information, especially for the latter years of the ten year time horizon, and is subject to change at the discretion of the utility. Much of the data submitted is preliminary in nature and is presented in a general manner. Specific and detailed data will be submitted as needed in the future as part of the Florida site certification process or other proceedings and filings.

This document is organized in the following manner:

Chapter I – Description of Existing Resources

This chapter provides an overview of FPL's current generating facilities. Also included is current information on other FPL resources including purchased power, demand side management, and FPL's transmission system.

Chapter II – Forecast of Electric Power Demand

FPL's load forecasting methodology, and its forecast of seasonal peaks and annual energy usage, is presented in Chapter II.

Chapter III – Projection of Incremental Resource Additions

This chapter discusses FPL's integrated resource planning (IRP) process and outlines FPL's projected resource additions, particularly new power plants, as determined by FPL's IRP work in 2004 and early 2005.

Chapter IV – Environmental and Land Use Information

This chapter discusses environmental information as well as preferred and potential site locations for additional electric generation facilities under consideration.

Chapter V – Other Planning Assumptions and Information

This chapter addresses twelve "discussion items" which pertain to additional specific information which is to be included in a Site Plan filing.

Executive Summary

Florida Power & Light Company's (FPL) 2005 Ten Year Power Plant Site Plan (Site Plan) addresses FPL's plans to meet its projected incremental resource needs for the 2005–2014 time period.

FPL's total generation capability is projected to significantly increase during the 2005–2014 time period as shown in Table ES.1. This table also shows the resulting projected Summer and Winter reserve margins for FPL over this ten-year time horizon.

Table ES.1 reflects FPL's planned changes to existing generation units (due to unit overhauls, etc.), scheduled changes in the delivered amount of purchased power, and the planned additions of new generating units. Although not specifically shown in this table, FPL's approved DSM Goals are assumed to be implemented on schedule.

The amount of new generating capacity that will be added is driven in part by the outcome of the Florida Public Service Commission docket No. 981890-EU. This docket ended with a stipulated agreement that resulted in FPL, along with Tampa Electric Company and Florida Power Corporation, switching from a minimum reserve margin planning criterion of 15% to one of 20% beginning with the Summer of 2004.

FPL has previously sought to partially secure needed capacity through a number of short-term and long-term firm capacity purchases from utilities and other entities. Included in the capacity additions for the 2005 through 2014 time frame are a new four-year firm purchase from Reliant's Indian River facility starting in 2006 and a five and a half-year firm purchase from Southern Company starting in 2010.

In 2005, FPL will be adding a large (1,107 Summer MW) new combined cycle (CC) unit at its existing Manatee plant site. Also in 2005, the two combustion turbines (CT's) that were added at FPL's existing Martin plant site in mid-2001 will be converted into a 1,107 Summer MW CC unit by the addition of two additional CT's, heat recovery steam generators, and associated equipment. This conversion will add another 787 Summer MW of capability above the present capability of the existing two CT's. The additions for 2005 were selected as the best options among other FPL construction alternatives and numerous proposals received in response to two Requests for Proposals (RFP's) FPL issued in August 2001 and April 2002, respectively. These two capacity additions were approved by the Florida Public Service Commission (FPSC) on November 19, 2002, and their applications for certification under the Florida Electric Power Plant Siting Act (Siting

Act) were approved by the Governor and Siting Board on April 11, 2003.

In 2007, FPL will be adding a large (1,144 Summer MW) new CC unit at its existing Turkey Point plant site. This unit was selected as the best option after comparison to other FPL construction alternatives and proposals received in response to an RFP that FPL issued in August 2003. This capacity addition was approved by the FPSC on June 18, 2004. On February 7, 2005, the Governor of Florida and Cabinet, acting as the Siting Board, approved the certification of the location, construction, and operation of the Turkey Point CC capacity addition.

FPL's 2008 capacity requirement will be met by a four-year purchase of varying capacity from Reliant's Indian River facility that starts in 2006 and continues through 2009. This purchase also has an option that would allow FPL to extend the purchase by one-year, through 2010.

FPL currently projects to meet its 2009 capacity need with the addition of a new self–build CC unit at its West County Energy Center site. FPL's 2010 capacity requirements will be met, in part, by the previously mentioned five and a half-year purchase from Southern Company. This 930 MW purchase begins in mid-2010 and continues through the end of 2015. In addition, FPL projects to meet the remainder of its 2010 capacity need and its 2011 capacity need with the addition of a second new self–build CC unit at its West County Energy Center site. These capacity addition selections will be conducted in a manner consistent with the Commission's Bid Rule through a Request for Proposal (RFP) process. Specifically, FPL intends to publish an RFP in the Summer of 2005 to solicit competitive proposals for comparison to its Next Planned Generating Unit(s) for the capacity need required in the years 2009 – 2011.

As noted on Table ES.1, the projected reserve margin for 2011 with these capacity additions is 19.7%, 75 MW under the 20% reserve margin planning standard. Should the need remain as currently forecast, FPL anticipates that it will make short-term purchases or other capacity adjustments as required to satisfy the reserve margin requirement. This situation presents itself again, to a lesser degree, in 2014.

Based on FPL's current forecast, there will be additional capacity needs of approximately 550 MW per year in the 2012 through 2014 time frame. Given the issue of fuel diversity, FPL proposes to meet that need with two supercritical pulverized coal (SCPC) units. These units will combine highly efficient and reliable supercritical pulverized coal combustion technology with advanced emissions control technology and plant design allowing for recycling of generation byproducts into useful commercial products, bringing a new generation of clean coal facilities to Florida. Current need projections for the in-service dates of the first and second units are June 2012 and June 2013, respectively. These planned increases in electric generation capability will allow FPL to continue to maintain system reliability and integrity at a reasonable cost and maintain the economic and reliability benefits of a diverse fuel mix. The clean coal units are discussed in detail in FPL's recent *Report on Clean Coal Generation*, provided to the Commission in March of 2005. FPL plans to publish a Clean Coal RFP on or before August 2006 for the capacity need required in the years 2012-2014. Because the objective of the Clean Coal RFP is to enhance fuel diversity, the Clean Coal RFP will be restricted to proposals for clean coal generation, or other proposals that enhance fuel diversity as effectively as clean coal generation. The Clean Coal RFP is being initiated with a lead time that will support the longer construction schedule of a clean coal plant.

FPL's 2004 planning efforts have continued to address two significant issues that can affect the reliability and cost of electricity in the FPL service territory. Those two issues are: 1) the economic impact of the imbalance in southeast Florida between regional load and generating capacity located within this region and, 2) addressing fuel diversity in the FPL system. The selection of the Turkey Point CC unit to meet FPL's 2007 resource need has helped mitigate the immediate imbalance in southeast Florida through the year 2010. The purchase of additional coal-fired generation through a purchase agreement, the development of a potential clean coal generation facility, and efforts to evaluate bringing Liquefied Natural Gas (LNG) supplies to Florida, are the steps FPL is pursuing to address fuel diversity concerns. FPL's approach to these two issues will continue to be incorporated into FPL's resource planning work and other related initiatives.

Projected Capacity Changes and Reserve Margins for FPL [1]

	TOTALS =	7,003	5,348		

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) These are firm capacity purchases with contract that existed on 12/31/03. See Section I.B, I.D and III.A. for more details.

(5) These are firm capacity purchases with contracts executed on/after 1/01/04.

(6) All new units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

Table ES.1

CHAPTER I

Description of Existing Resources

(This page is left intentionally blank.)

I. Description of Existing Resources

FPL's service area contains approximately 27,650 square miles and has a population of approximately 8 million people. FPL served an average of 4,224,509 customer accounts in thirty-five counties during 2004. These customers were served from a variety of resources including: FPL-owned fossil and nuclear generating units, non-utility owned generation, demand side management, and interchange/purchased power.

I.A. FPL-Owned Resources

The existing FPL generating resources are located at fourteen generating sites distributed geographically around its service territory and also include partial ownership of one unit located in Georgia and two units located in Jacksonville, FL. The current generating facilities consist of four nuclear steam units, three coal units, nine combined cycle units, seventeen fossil steam units, forty-eight combustion gas turbines, two simple cycle combustion turbines, and five diesel units. The location of these units is shown on Figure I.A.1 and in Table 1.A.1.

The bulk transmission system is composed of 1,104 circuit miles of 500 Kilovolt (KV) lines (including 75 miles of 500 KV lines [two 37-1/2 mile lines] between Duval Substation and the Florida-Georgia state line, which are jointly owned with Jacksonville Electric Authority) and 2,753 circuit miles of 230 KV lines. The underlying network is composed of 1,584 circuit miles of 138 KV lines, 717 circuit miles of 115 KV lines, and 164 circuit miles of 69 KV transmission lines. Integration of the generation, transmission, and distribution system is achieved through FPL's 537 substations.

The existing FPL system, including generating plants, major transmission stations, and transmission lines, is shown on Figure I.A.2. In addition, Figure I.A.3 shows FPL's interconnection ties with other utilities.

Capacity Resources by Location
(as of December 31, 2004)

Location/ Map Key	Plant Name	Number of Units	Summer MW

I.B Non-Utility Generation

Non-utility generation is an important part of FPL's resource mix. FPL currently has contracts with seven cogeneration/small power production facilities to purchase firm capacity and energy. A listing of these facilities appears in Table I.B.1. In addition, FPL purchases as-available (non-firm) energy from several cogeneration facilities and small power production facilities as shown in Table I.B.2.

A cogeneration facility is one which simultaneously produces electrical and thermal energy, with the thermal energy (e.g., steam) being used for industrial, commercial, or cooling and heating purposes. A small power production facility is one which does not exceed 80 MW (unless it is exempted from this size limitation by the Solar, Wind, Waste, and Geothermal Power Production Incentives Act of 1990) and uses as its primary energy source (at least 50%) solar, wind, waste, geothermal, or other renewable resources.

Table I.B.2

I.C. Demand Side Management (DSM)

FPL's DSM activities continue what has been FPL's practice since 1978 of encouraging cost-effective conservation and load management. FPL's DSM efforts through 2004 have resulted in a cumulative Summer peak reduction of approximately 3,418 MW at the generator and an estimated cumulative energy saving of 29,050 GWH at the generator.

FPL's new DSM Goals for the 2005-2014 time frame were approved by the Florida Public Service Commission (Commission) on August 9, 2004. FPL's 2004 resource planning work, and the schedule for new generation additions presented in this document, are based on these approved DSM levels. FPL filed its DSM Plan (with which FPL will meet the approved DSM Goals) on November 30, 2004 with the Commission. The Commission approved FPL's DSM Plan in March 2005.

I.D. Purchased Power

Purchased power remains an important part of FPL's resource mix. FPL has a Unit Power Sales (UPS) contract to purchase 931 MW, with a minimum of 381 MW, of coal-fired generation from the Southern Company (Southern) through May, 2010. In January 2005, the Commission approved a new firm purchase contract with Southern that will result in FPL receiving 930 MW from June 2010 through the end of 2015. This capacity will be supplied by Southern from a mix of gas-fired and coal-fired units.

In addition, FPL has contracts with the Jacksonville Electric Authority (JEA) through mid-2021 for the purchase of 381 MW (Summer) and 390 MW (Winter) of coal-fired generation from the St. John's River Power Park (SJRPP) Units No. 1 and No. 2 (FPL also has ownership interest in these units; that ownership amount is reflected in FPL's installed capacity shown on Figure I.A.1, in Table I.A.1, and on Schedule 1).

Finally, FPL has additional firm capacity purchase contracts through 2009. These firm capacity purchase contracts are with a variety of suppliers. Table I.D.1 presents the Summer and Winter MW resulting from all firm purchased power contracts through the year 2014.

	FPL's Purchased Power MW (1)							
	UPS		SJRPP		Other Firm Capacity Purchases		Total	
Year	Winter	Summer	Winter	Summer	Winter	Summer	Winter	Summer
2004 (2)	931	931	390	381	1,164	1,495	2,485	2,807
2005	931	931	390	381	1,008	935	2,329	2,247
2006	931	931	390	381	1,138	1,065	2,459	2,377
2007	931	931	390	381	1,362	354	2,683	1,666
2008	931	931	390	381	576	576	1,897	1,888
2009	931	931	390	381	250	250	1,571	1,562
2010	931	0	390	381	0	930	1,321	1,311
2011	0	0	390	381	930	930	1,320	1,311
2012	0	0	390	381	930	930	1,320	1,311
2013	0	0	390	381	930	930	1,320	1,311
2014	0	0	390	381	930	930	1,320	1,311

Note:

(1) Total reflects total resource entitlements resulting from existing agreements between FPL, Southern Companies, JEA, and from new firm purchase agreements.

(2) Values for 2004 are actual.

CHAPTER II

Forecast of Electric Power Demand

(This page is left intentionally blank.)

II. Forecast of Electric Power Demand

Long-term (20-year) forecasts of sales, net energy for load (NEL), and peak loads are developed on an annual basis for resource planning work at FPL. These forecasts are a key input to the models used to develop the Integrated Resource Plan. The following pages describe how forecasts are developed for each component of the long-term forecast: sales, NEL, and peak loads.

The primary drivers to develop these forecasts are demographic trends, weather, economic conditions, and prices of electricity. In addition, the resulting forecasts are an integration of economic evaluations, inputs of local economic development boards, weather assessments from the National Oceanic and Atmospheric Administration (NOAA), and inputs from FPL's own customer service planning areas. In the area of demographics, population trends by county, plus housing characteristics such as housing starts, housing size, and vintage of homes, are assessed.

Forecasts for electric usage in the residential and commercial classes include end-use information such as appliance saturation studies, efficiencies, and intensity of energy use. In addition to these inputs, residential forecasts also make use of household characteristics such as ages of members in households, number of members in households, and income distributions.

The projections for the national and Florida economy are obtained from Global Insight, an international economic consulting firm. Population projections for the counties served by FPL are obtained from the Bureau of Economic and Business Research (BEBR) of the University of Florida. In addition, FPL actively participates with local development councils and universities to obtain their assessments of the local economy, specifically in the area of expansion of new businesses and retention of the current business base. These inputs are quantified and qualified using statistical models in terms of their impact on the future demand for electricity.

Weather is always a key factor that affects the company's sales and peak demand. Weather variables are used in the forecasting models for energy sales and peak demand. There are two sets of weather variables developed and used in forecasting models:

1. Cooling and Heating Degree-Days are used to forecast energy sales.
2. Temperature data is used to forecast Summer and Winter peaks.

The Cooling and Heating Degree-Days are used to capture the changes in the electric usage of weather-sensitive appliances such as air conditioners and electric space heaters. A composite temperature hourly profile is derived using hourly temperatures across FPL's service territory (Miami, Ft. Myers, Daytona Beach, and West Palm Beach are the locations from which temperatures are obtained) weighted by regional energy sales. This composite temperature is used to derive Cooling and Heating Degree-Days which are based on starting point temperatures of 72°F and 66°F, respectively. Similarly, the maximums and minimums of the composite temperature hourly profile are used for the Summer and Winter peak models.

1. Impact of 2004 Hurricanes

FPL has estimated the impact of the 2004 hurricanes on its projected customer growth and resulting demand forecasts. These estimates were based, in part, on FPL's experience following Hurricane Andrew. After Hurricane Andrew, population growth declined to a level of approximately 65,000 customers per year and remained at that level for approximately six years before returning to a more robust growth rate. FPL's customer growth reached a peak in August 2004, with 120,000 customers having been added for the preceding 12 months. However, as a consequence of the three South Florida hurricanes (Charley, Frances, and Jeanne), growth significantly declined.

Before the hurricanes hit Florida in 2004, FPL was projecting an annual increase of 80,000 new customers in 2005, 82,000 new customers in 2006, and 81,000 new customers in 2007. When the impact of the 2004 hurricanes is taken into account, the resulting projections are 72,000 new customers in 2005, 75,000 in 2006, and a return to trend of 80,000 in 2007. FPL is assuming that the impact of the 2004 hurricanes will be short-lived and customer growth will return to a more normal level in a couple of years, versus the six year impact of Hurricane Andrew. This difference is primarily due to the assumption that the population growth in Florida will be fueled by larger numbers of baby-boomers retiring and moving to Florida, as well as an increasing availability of jobs.

II.A. Long-Term Sales Forecasts

Long-term forecasts of electricity sales are developed for each revenue class for the forecasting period of 2004-2023 and are adjusted to match the Net Energy for Load (NEL) forecast. The results of these sales forecasts for the years 2005-2014 are presented in

Schedules 2.1-2.3 which appear at the end of this chapter. Econometric models are developed for each revenue class using the statistical tool MetrixND. The methodologies used to develop sales forecasts for each jurisdictional revenue class are outlined below. The first five years of the forecasts are developed using monthly models for Net Energy for Load and energy sales by class.

1. Residential Sales

Residential electric usage per customer is estimated by using a regression model which contains the real residential price of electricity, real Florida personal income, and Cooling and Heating Degree-Days as explanatory variables as well as a dummy variable for shoulder months. The price of electricity plays a role in explaining electric usage since electricity, like all other goods and services, will be used in greater or lesser quantities depending upon its price. To capture economic conditions, the model includes Florida's real personal income. The degree of economic prosperity can, and does, affect residential electricity sales. The impact of weather is captured by the Cooling and Heating Degree-Days; in addition, a one month lagged Cooling Degree-Day is also included as an explanatory variable. Residential energy sales are forecast by multiplying the residential use per customer forecast by the number of residential customers forecasted

2. Commercial Sales

The commercial sales forecast is also developed using a regression model. Commercial sales are a function of the following variables: Florida's non-agricultural employment, commercial real price of electricity, Cooling Degree-Days, and an autoregressive term. Florida's non-agricultural employment is used to capture the economic activity in FPL's service territory. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. Cooling Degree-Days are used to capture weather-sensitive load in the commercial sector.

3. Industrial Sales

The industrial sales forecast is also developed using a regression model. Industrial sales are a function of industrial customers, the price of electricity, Cooling Degree-Days, a dummy variable for outliers, and an autoregressive term. The price of electricity is also included as an explanatory variable in the model because it has an impact on customer usage. The Cooling Degree-Day term is included to capture the weather-sensitive load in the industrial class.

4. Other Public Authority Sales

At present, this class consists of sports fields and one government account. The forecast for this class is based on historical knowledge of its characteristics.

5. Street & Highway Sales and Railroad & Railways Sales

The forecast for street and highway sales is developed by first assuming a constant use per customer and then multiplying that value by the number of projected customers. The forecast of sales to railroad & railways is based on historical knowledge of its characteristics. This class consists of Miami-Dade County's Metrorail system.

6. Sales for Resale

Sales for resale (wholesale) customers are composed of municipalities and/or electric cooperatives. These customers differ from jurisdictional customers in that they are not the ultimate users of the electricity they buy. Instead, they resell this electricity to their own customers.

Currently, there are four customers in this class: the Florida Keys Electric Cooperative (Florida Keys), City Electric System of the Utility Board of Key West, Florida (City of Key West), Miami-Dade County, and the Florida Municipal Power Agency (FMPA). Sales to the Florida Keys are forecasted using a regression model. Forecasted sales to the City of Key West are based on assumptions regarding their contract demand and expected load factor. Miami-Dade County sells 60 MW to Progress Energy. Line losses are billed to Miami-Dade under a wholesale contract. FMPA has contracted for delivery of 75 MW from FPL through October, 2007.

7. Total Sales

Sales forecasts by revenue class are summed to produce a total sales forecast. After an estimate of annual total sales is obtained, an expansion factor is applied to generate a forecast of annual Net Energy for Load (NEL).

II.B. Net Energy for Load

An annual econometric model is developed to produce a net energy for load (NEL) forecast. The key inputs to the model are: the price of electricity, Heating and Cooling Degree-Days, Florida Non-Agricultural Employment, and an autoregressive term. The monthly model is similar, except the economic variables utilized are Florida's real personal income and a dummy variable for February. The first five years are obtained from the short-term model. Forecasts for subsequent years are generated using the growth rates from the annual model.

Once an annual NEL forecast is obtained using the above-mentioned methodology, the results are then compared for reasonableness to the NEL forecast generated using the total sales forecast. The sales by class forecasts previously discussed are then adjusted to match the annual NEL Forecast.

The forecasted NEL values for 2005–2014 are presented in Schedule 3.3 that appears at the end of this chapter.

II.C. System Peak Forecasts

The rate of absolute growth in FPL system load has been a function of an increase in the customer base, varying weather conditions, continued economic growth, changing patterns of customer behavior (including an increased stock of electricity-consuming appliances), and more efficient heating and cooling appliances. FPL developed the peak forecast models to capture these behavioral relationships.

The forecasting methodology of Summer, Winter, and monthly system peaks is discussed below. The forecasted values for Summer and Winter peak loads for the years 2005–2014 are presented in Schedules 3.1 and 3.2 that appear at the end of this chapter, and again in Schedules 7.1 and 7.2 that appear near the end of Chapter 3.

System Summer Peak

The Summer peak forecast is developed using an econometric model. The variables included in the model are the price of electricity, Florida real personal income, and maximum peak day temperature. The econometric model uses these variables to develop the Summer peak load per customer. The Summer peak load per customer value is multiplied by total customers to derive FPL's system Summer peak.

System Winter Peak

Like the system Summer peak model, this model is also an econometric model. The model consists of two weather-related variables: the minimum temperature on the peak day and Heating Degree-Hours for the prior day as well as for the morning of the Winter peak day. In addition, Florida real personal income is a variable used in the model. The model generates the Winter peak load per customer. The Winter peak load per customer value is multiplied by total customers to derive FPL's system Winter peak.

Monthly Peak Forecasts

Monthly peaks for the 2004-2023 period are forecasted to provide information for the scheduling of maintenance for power plants and fuel budgeting. The forecasting process is basically the same as for the monthly NEL forecast and consists of the following actions:

a. Develop the historical seasonal factor for each month by using ratios of historical monthly peaks to seasonal peaks (Summer = April-October, Winter = November-March.)

b. Apply the monthly ratios to their respective seasonal peak forecast to derive the peak forecast by month. This process assumes that the seasonal factors remain unchanged over the forecasting period.

II.D. The Hourly Load Forecast

Forecasted values for system hourly load for the period 2004-2023 are produced using a System Load Forecasting "shaper" program. This model uses sixteen years of historical FPL hourly system load data to develop load shapes for weekdays, weekend days, and holidays. These daily load shapes are ranked and used with forecasted monthly peaks, NEL, and calendars in developing an hourly forecast. The model allows calibration of hourly values where the peak is maintained or where both the peak and minimum load–to-peak ratio is maintained.

Historical Values (1995 - 2004):

Col. (2) - Col. (4) are actual values for historical summer peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col. (9) for 1995 through 2003 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial /Industrial Demand Reduction (CDR). Col.(5) - Col.(9) for year 2004 are "estimated actuals" and are August values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula:Col. (10) = Col.(2) - Col.(6) - Col.(8).

Projected Values (2005 - 2014):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col. (9) represent all incremental conservation and cumulative load control. These values are projected August values and the conservation values are based on projections with a 1/2004 starting point for use with the 2004 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Historical Values (1995/96 - 2004/05):

Col. (2) - Col. (4) are actual values for historical winter peaks. As such, they incorporate the effects of conservation (Col. 7 & Col. 9), and may incorporate the effects of load control if load control was operated on these peak days. Therefore, Col. (2) represents the actual Net Firm Demand.

Col. (5) - Col.(9) for 1995/96 through 2003/04 represent actual DSM capabilities starting from January 1988 and are annual (12-month) values. Note that the values for FPL's former Interruptible Rate are incorporated into Col. (8), which also includes Business On Call (BOC) and Commercial/Industrial Demand Reduction (CDR).Col.(5) - Col.(9) for year 2004/05 are "estimated actuals" and are January values.

Col. (10) represents a HYPOTHETICAL "Net Firm Demand" if the load control values had definitely been exercised on the peak. Col. (10) is derived by the formula: Col. (10) = Col. (2) - Col. (6) - Col. (8).

Projected Values (2005/06- 2013/14):

Col. (2) - Col.(4) represent FPL's forecasted peak w/o incremental conservation or cumulative load control. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) - Col.(9) represent all incremental conservation and cumulative load control. These values are projected January values and the conservation values are based on projections with a 1/2004 starting point for use with the 2004 load forecast.

Col. (10) represents a 'Net Firm Demand" which accounts for all of the incremental conservation and assumes all of the load control is implemented on the peak. Col. (10) is derived by using the formula: Col. (10) = Col. (2) - Col. (5) - Col. (6) - Col. (7) - Col. (8) - Col. (9).

Schedule 3.3
History and Forecast of Annual Net Energy for Load - GWH: Base Case

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
Year	Total	Residential Conservation	C/I Conservation	Retail	Sales for Resale GWH	Utility Use & Losses	Net Energy For Load	Load Factor(%)
1995	85,418	777	680	83,981	1,437	6,276	83,961	59.3%
1996	87,007	971	1,043	85,654	1,353	6,306	84,993	60.2%
1997	89,243	1,213	1,177	88,015	1,228	5,771	86,853	59.7%
1998	95,318	1,374	1,282	93,992	1,326	6,206	92,662	59.1%
1999	94,365	1,542	1,365	93,412	953	5,829	91,458	59.3%
2000	99,097	1,674	1,434	98,127	970	7,059	95,989	61.4%
2001	101,739	1,789	1,545	100,768	970	7,222	98,404	59.9%
2002	107,755	1,917	1,639	106,522	1,233	7,443	104,199	61.9%
2003	112,160	2,008	1,759	110,648	1,511	7,386	108,393	62.9%
2004	112,036	2,109	1,836	110,504	1,531	7,464	108,091	59.9%
2005	111,695	59	17	110,127	1,568	7,700	111,619	61.9%
2006	115,463	148	45	113,876	1,586	7,813	115,270	62.2%
2007	119,477	235	61	117,919	1,558	8,068	119,181	62.7%
2008	123,459	327	70	122,366	1,092	8,331	123,062	63.0%
2009	127,521	425	80	126,429	1,092	8,616	127,016	63.6%
2010	130,980	528	90	129,887	1,092	8,849	130,362	63.8%
2011	133,674	635	101	132,582	1,092	9,031	132,938	63.7%
2012	136,387	745	111	135,295	1,092	9,215	135,531	63.3%
2013	139,429	858	123	138,337	1,092	9,420	138,448	63.5%
2014	142,692	974	134	141,600	1,092	9,641	141,584	63.5%

Historical Values (1995 - 2004):

Col. (2) represents derived "Total Net Energy For Load w/o DSM". The values are calculated using the formula: Col. (2) = Col. (3) + Col. (4) + Col. (8).

Col.(3) & Col.(4) for 1995 through 2003 are DSM values starting in January 1988 and are annual (12-month) values.Col. (3) and Col. (4) for 2004 are "estimated actuals" and are also annual (12-month) values. The values represent the total GWH reductions actually experienced each year .

Col. (5) & Col. (6) are a breakdown of Net Energy For Load in Col (2) into Retail and Wholesale .

Col. (9) is calculated using Col. (8) from this page and Col. (2), "Total", from Schedule 3.1 using the formula: Col. (9) = ((Col. (8)*1000) / ((Col.(2) * 8760)

Projected Values (2005 - 2014):

Col. (2) represents Net Energy for Load w/o DSM values. The values are extracted from Schedule 2.3, Col. (19).

Col. (3) & Col. (4) are forecasted values of the reduction on sales from incremental conservation and are mid-year (6-month) values. The effects of conservation implemented prior to 2004 are incorporated into the load forecast.

Col. (5) & Col. (6) are a breakdown of Net Energy For Load in Col (2) , into Retail and Wholesale.

Col. (8) NEL projected values shown here do include the impact of conservation in Col. (3) and Col. (4). Therefore, these NEL values do not match those shown on schedule 2.3 because those values do not account for incremental conservation.

Col. (9) is calculated using Col. (2) from this page and Col. (2), "Total", from Schedule 3.1. Col. (9) = ((Col. (2)*1000) / ((Col. (2) * 8760)
Adjustments are made for leap years.

Schedule 4
Previous Year Actual and Two-Year Forecast of Retail Peak Demand and Net Energy for Load (NEL) by Month

(1)	(2)	(3)	(4)	(5)	(6)	(7)
	2004 ACTUAL		2005* FORECAST		2006* FORECAST	
Month	Total Peak Demand MW	NEL GWH	Total Peak Demand MW	NEL GWH	Total Peak Demand MW	NEL GWH

TOTALS		108,091		111,695		115,463

* Forecasted Peaks & NEL do not include the impacts of cumulative load management and incremental conservation and are consistent with values shown in Col. (19) of Schedule 2.3 and Col (2) of Schedule 3.3.

CHAPTER III

Projection of Incremental Resource Additions

(This page is left intentionally blank.)

III. Projection of Incremental Resource Additions

III.A FPL's Resource Planning:

FPL developed an integrated resource planning (IRP) process in the early 1990's and has since utilized the process to determine when new resources are needed, what the magnitude of the needed resources are, and what type of resources should be added. The timing and type of potential new power plants, the primary subjects of this document, are determined as part of the IRP process work. This section discusses how FPL applied this process in its 2004 and early 2005 resource planning work.

Four Fundamental Steps of FPL's Resource Planning:

There are 4 fundamental "steps" to FPL's resource planning. These steps can be described as follows:

Step 1: Determine the magnitude and timing of FPL's new resource needs;

Step 2: Identify which resource options and resource plans can meet the determined magnitude and timing of FPL's resource needs (i.e., identify competing options and resource plans);

Step 3: Determine the economics for the total utility system with each of the competing options and resource plans; and,

Step 4: Select a resource plan and commit, as needed, to near-term options.

Figure III.A.1 graphically outlines the 4 steps.

Overview of FPL's IRP Process

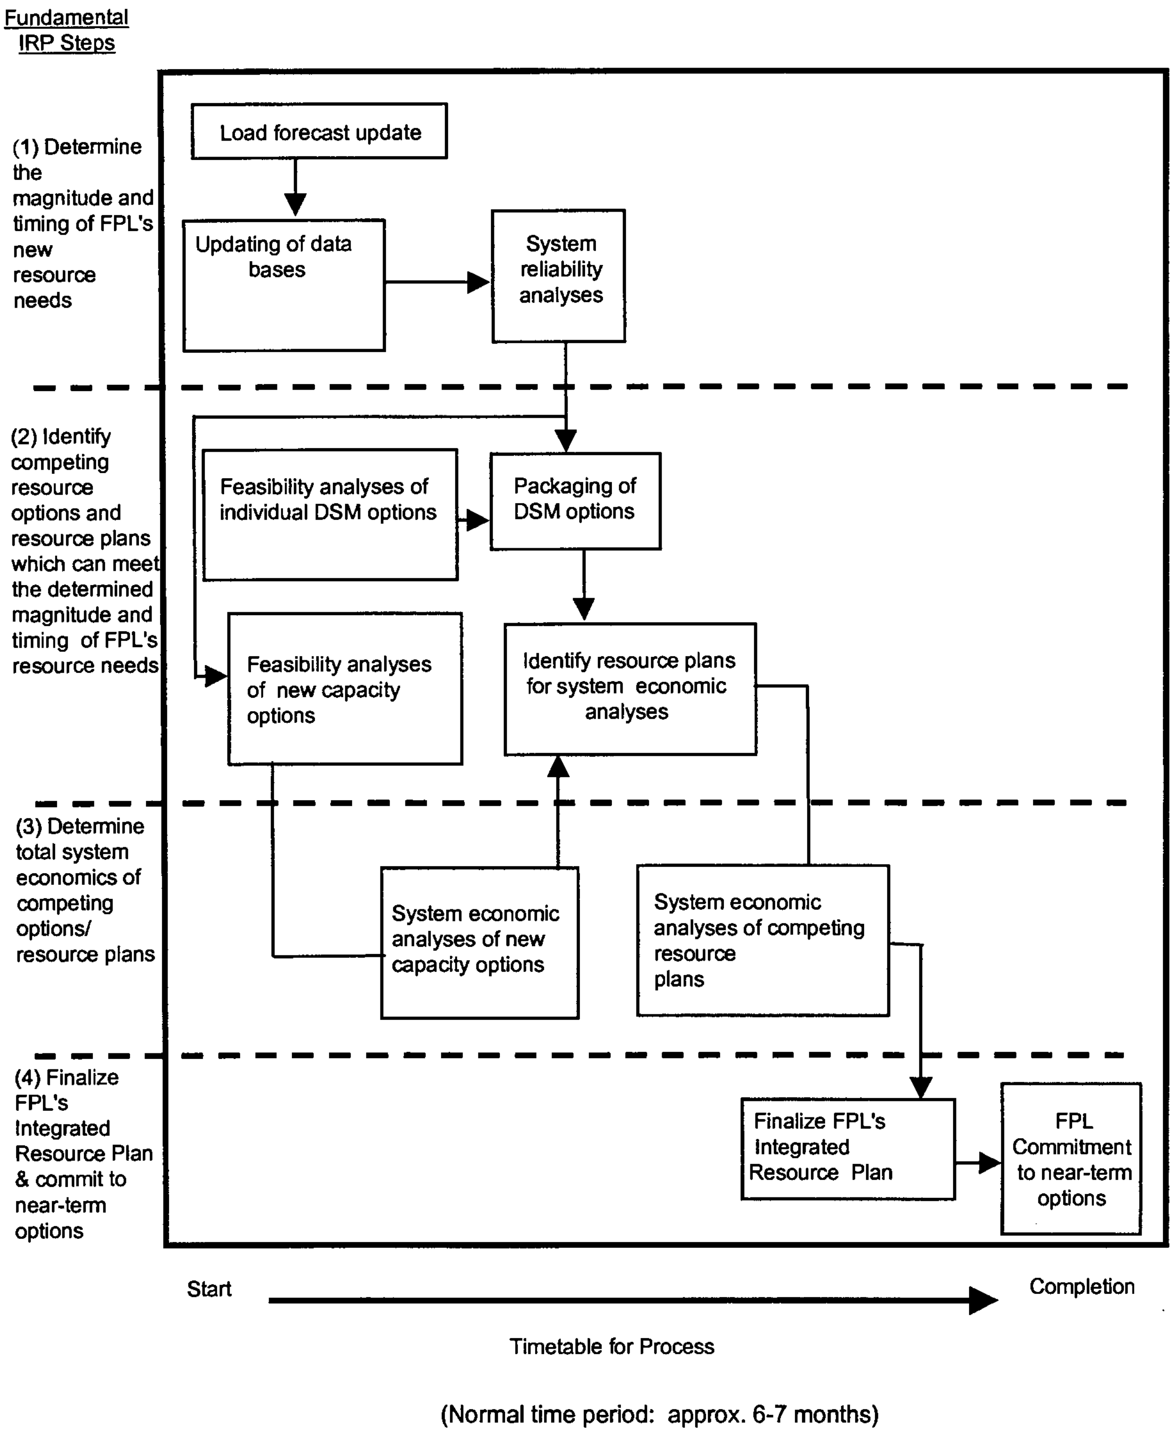

Figure III.A.1

Step 1: Determine the Magnitude and Timing of FPL's New Resource Needs:

The first of these four resource planning steps–determining the magnitude and timing of FPL's resource needs–is essentially a determination of the amount of capacity or megawatts (MW) of load reduction, new capacity additions, or a combination of both load reduction and new capacity additions that are needed. Also determined in this step is when the MW are needed to meet FPL's planning criteria. This step is often referred to as a resource adequacy or reliability assessment for the utility system.

Step 1 starts with an updated load forecast. Several databases are also updated in this first fundamental step, not only with the new information regarding forecasted loads, but also with other information which is used in many of the fundamental steps in resource planning. Examples of this new information include: delivered fuel price projections, current financial and economic assumptions, and power plant capability and reliability assumptions. FPL also includes key assumptions regarding three specific resource areas: (1) near-term construction capacity additions, (2) short-term, firm capacity purchase additions, and (3) long-term DSM implementation.

The first of these assumptions is based on FPL's ongoing engineering and construction activities to add near-term capacity through various projects. These construction projects include the addition of a new combined cycle (CC) unit at Manatee and the conversion of two existing CT's at Martin into a new CC unit. Both additions are scheduled to come in-service in mid-2005. The additions were approved by the Florida Public Service Commission (FPSC) in November 2002 after comparing them to 134 competing bids that were received in response to two Requests for Proposals (RFP's) that solicited bids for meeting FPL's 2005/2006 capacity needs. In addition, a new CC unit at FPL's Turkey Point site is planned to come in-service in mid-2007. FPL selected this capacity option after conducting an RFP during the last part of 2003. The addition was approved by the FPSC in June of 2004 and the Governor and Siting Board approved certification of the plant location, construction, and operation of the new CC unit in February, 2005.

The second of these assumptions involves short-term, firm capacity purchase additions. These firm capacity purchases are from a combination of utility and independent power producers. The total capacity and duration of these purchases have changed somewhat from what was presented in last year's Site Plan. These changes include a new firm purchase from Reliant's Indian River facility of up to 576 MW from 2006 through 2009, with an option to extend the purchase through 2010. In addition, in January 2005 the

FPSC approved a five and one half-year firm purchase of 930 MW from the Southern Company that was identified as a projected purchase in FPL's prior Site Plan. The annual total capacity values for these purchases are presented in Table I.D.1. These purchased capacity amounts were incorporated in FPL's recent resource planning work.

The third of these assumptions involves DSM. Since 1994, FPL's resource planning work has used the DSM MW called for in FPL's approved DSM Goals as a "given" in its analyses. This was again the case in FPL's most recent planning work, as its new DSM Goals that address the years 2005 through 2014, and that were approved by the FPSC in August 2004, were taken as a "given".

The assumptions and much of the other updated information and assumptions are then applied in the first fundamental step: the determination of the magnitude and the timing of FPL's resource needs. This determination is accomplished by system reliability analyses which are typically based on a dual planning criteria of a minimum peak period reserve margin of 20% (FPL applies this to both Summer and Winter peaks) and a maximum loss–of-load probability (LOLP) of 0.1 day per year. Both of these criteria are commonly used throughout the utility industry. (FPL's reserve margin criterion increased from 15% to 20% starting in mid-2004 due to a voluntary agreement reached among FPL, FPC, and TECO, and accepted by the FPSC in FPSC Docket No. 981890-EU.)

Historically, two types of methodologies, deterministic and probabilistic, have been employed in system reliability analysis. The calculation of excess firm capacity at the annual system peaks (reserve margin) is the most common method, and this relatively simple deterministic calculation can be performed on a spreadsheet. It provides an indication of the adequacy of a generating system's capacity resources compared to its native load during peak periods. However, deterministic methods do not take into account probabilistic-related elements such as the impact of individual unit failures. For example: two 50 MW units which can be counted on to run 90% of the time are more valuable in regard to utility system reliability than is one 100 MW unit which can also be counted on to run 90% of the time. Probabilistic methods also recognize the value of being part of an interconnected system with access to multiple capacity sources.

For this reason, probabilistic methodologies have been used to provide an additional perspective on the generation resource adequacy of a generating system. There are a number of probabilistic methods that are being used to perform system reliability analyses. Of these, the most widely used is loss–of-load probability or LOLP. Simply stated, LOLP is an index of how well a generating system may be able to meet its demand (i.e., a measure of how often load may exceed available resources). In contrast to reserve margin, the calculation of LOLP looks at the daily peak demands for each year, while taking into consideration such probabilistic events as the unavailability of individual generators due to scheduled maintenance or forced outages.

LOLP is expressed in units of the "number of times per year" that the system demand could not be served. The standard for LOLP accepted throughout the industry is a maximum of 0.1 day per year. This analysis requires a more complicated calculation methodology than does the reserve margin analysis. LOLP analyses are typically carried out using computer software models such as the Tie Line Assistance and Generation Reliability (TIGER) program currently used by FPL.

The result of the first fundamental step of resource planning is a projection of how many new MW of resources are needed to meet both reserve margin and LOLP criteria, and thus maintain system reliability, and of when the MW are needed. This information is used in the second fundamental step: identifying resource options and resource plans that can meet the determined magnitude and timing of FPL's resource needs.

Step 2: Identify Resource Options and Plans That Can Meet the Determined Magnitude and Timing of FPL's Resource Needs:

The initial activities associated with this second fundamental step of resource planning generally proceed concurrently with the activities associated with Step 1. During Step 2, feasibility analysis of new capacity options are carried out to determine which new capacity options appear to be the most competitive on FPL's system. These analyses also establish capacity size (MW) values, projected construction/permitting schedules, and operating parameters and costs.

The individual new capacity options are then "packaged" into different resource plans which are designed to meet the system reliability criteria. In other words, resource plans are created by combining individual resource options so that the timing and magnitude of FPL's new resource needs are met. The creation of these competing resource plans is typically carried out using dynamic programming techniques. For planning purposes, only FPL construction options are typically included in these analyses.

At the conclusion of the second fundamental resource planning step, a number of different combinations of new resource options (i.e., resource plans) of a magnitude and timing necessary to meet FPL's resource needs were identified. These resource plans were then compared on an economic basis.

Step 3: Determining the Total System Economics:

At the completion of fundamental steps 1 & 2, the most viable new resource options have been identified, and these resource options have been combined into a number of resource plans which meet the magnitude and timing of FPL's resource needs. The stage is set for comparing the system economics of these resource plans. In its 2004 resource planning work, FPL performed much of this work of combining resource options into resource plans using the EGEAS (Electric Generation Expansion Analysis System) computer model from the Electric Power Research Institute (EPRI). The EGEAS model was also used to perform much of the basic economic analyses of the resource plans. For various analyses, FPL applied the P-MArea (P-Month) production cost model to develop an additional perspective of the production costs for the various resource plans developed in the EGEAS model. The P-MArea model is the model used by FPL to develop the Fuel Cost Budget and to conduct other production cost-related analyses.

In 2004, FPL also utilized several other models in its resource planning work. For the work carried out for the DSM Goals and DSM Plan dockets, FPL used its CPF model–an FPL spreadsheet model utilizing the FPSC's approved cost-effectiveness methodology-for analyzing the cost-effectiveness of individual DSM measures/programs and its linear programming model for creating and analyzing combinations of DSM options that constitute multi-year DSM implementation plans.

The basic economic analyses of the competing resource plans focus on total system economics. The standard basis for comparing the economics of competing resource plans is their relative impact on FPL's electricity rate levels, with the intent of minimizing FPL's leveled system average rate (i.e., a Rate Impact Measure or RIM methodology). However, in cases such as existed for FPL's most recent planning work in which the DSM contribution was assumed as planned and the only competing options were new generating units, and purchase options, comparisons of competing resource plans' impacts on electricity rates and on system revenue requirements are equivalent. Consequently, the competing options and plans were evaluated on a present value system revenue requirement basis that includes the system capital and operating costs of the new capacity options.

Step 4: Finalizing FPL's Current Resource Plan

The results of the previous three fundamental steps were used to develop the future generation plan. This plan is presented in the following section.

III.B Incremental Resource Additions

FPL's projected incremental generation capacity additions/changes for 2005 through 2014 are depicted in Table III.B.1 (the planned DSM additions are shown separately in Table III.C.1). These capacity additions/changes result from a variety of actions including: changes to existing units (which are frequently achieved as a result of plant component replacements during major overhauls or by unit conversion from one type of unit to another), changes in the amounts of purchased power being delivered under existing contracts as per the contract schedules or by entering into new purchase contracts, and by projected construction of new generating units.

As shown in Table III.B.1, the capacity additions are largely made up of new construction, new purchases, and proposed self-build alternatives. The new construction contribution is made up of three projects: the conversion of two CT's into a larger CC unit in 2005 at FPL's Martin site; the addition of a new CC unit in 2005 at FPL's Manatee site, and the addition of a new CC unit in 2007 at FPL's Turkey Point site. FPL has negotiated the addition of firm capacity of varying amounts through a purchase power contract with Reliant's Indian River facility during the years 2006 through 2009 and with the Southern Company during the time period from mid-2010 through 2015. FPL projects the construction of two new CC units at the proposed West County Energy Center site in Palm Beach County, one in 2009 and one in 2010, and the proposed addition of two new clean coal technology units, one each in 2012 and 2013. The issues surrounding clean coal units are discussed in more detail in FPL's recent *Report on Clean Coal Generation*, provided to the Commission in March of 2005.

The above capacity additions address the projected resource needs from FPL's reliability analyses. For 2008, FPL's projected resource need is relatively small, approximately 470 MW. For each year from 2009 through 2013, the projected annual resource need is significantly larger; in the range of approximately 550 MW to 850 MW each year.

Projected Capacity Changes and Reserve Margins for FPL (1)			
		Net Capacity Changes (MW)	
		Winter (2)	***Summer*** (3)
2005	Changes to Existing Purchases (4)	(166)	(566)
	Manatee Unit #3 Combined Cycle (6)	---	1,107
	Conversion of Martin #8 CT's to CC (6)	0	787

	Unsited Clean Coal Unit # 2 (6)	---	850
2014	Unsited Clean Coal Unit # 2 (6)	855	---
	TOTALS =	**7,003**	**5,348**

(1) Additional information about these resulting reserve margins and capacity changes are found on Schedules 7 & 8 respectively.

(2) Winter values are values for January of year shown.

(3) Summer values are values for August of year shown.

(4) These are firm capacity purchases with contract that existed on 12/31/03. See Section I.B, I.D and III.A. for more details.

(5) These are firm capacity purchases with contracts executed on/after 1/01/04.

(6) All new units are scheduled to be in-service in June of the year shown. Consequently, they are included in the Summer reserve margin calculation for the in-service year and in both the Summer and Winter reserve margin calculations for subsequent years.

Table III.B.1

III.C Other Results of FPL's Recent Planning Work

FPL's 2004 and early 2005 planning efforts have continued to address two issues that were identified in FPL's 2003 Site Plan. Those two issues are: (1) the need to address the imbalance between regional load and generating capacity located in southeast Florida, and (2) the desire to maintain and enhance fuel diversity in the FPL system.

1. Southeast Imbalance

There continues to be an imbalance between regionally installed generation and peak load in southeast Florida. A significant amount of energy required in the southeast region during peak periods is provided through the transmission system from plants located outside the region. Based on the forecast for continued load growth in this region, the imbalance between generation and load will increase unless additional generation capacity is periodically located within this region or additional transmission delivery capability is constructed.

FPL's prior planning work had concluded that either additional installed capacity in this region or transmission capacity capable of delivering additional electricity from outside the region would be required to address this imbalance. Delivering additional electricity from outside the region increases transmission-related costs and incurs the cost of the additional capacity.

The evaluation conducted as part of FPL's 2003 Request for Proposal (RFP) process met FPL's 2007 need by considering all cost components of FPL's next planned generating unit (NPGU) and alternative options, including transmission-related costs. The location of the NPGU and the locations of proposed units included in the alternative option combinations contributed to the transmission-related costs determined in the evaluation. The results of the RFP evaluation confirmed that because of the existing imbalance, generating units located in the southeast region contribute significantly lower transmission-related costs than do those located outside the region.

Partly because of the lower transmission-related costs resulting from its location, Turkey Point Unit # 5, was evaluated as the most cost-effective option to meet FPL's 2007 capacity need. Adding Turkey Point Unit # 5 will significantly reduce the imbalance between generation and load in southeast Florida. However, assuming no other resources are added, the imbalance will re-develop to the pre-Turkey Point Unit # 5 levels within 3 to 4 years because of the continued load growth of approximately 250-300 MW per year in this region. Therefore, the re-emergence of the southeast imbalance is expected to remain a factor in the calculation of transmission-related costs which are an integral part of the evaluation of new capacity additions. This factor has contributed to the identification in the Site Plan of two new CC units to be added in 2009 and 2010 at the proposed West County Energy Center site in Palm Beach County. The location of these proposed capacity additions would continue to mitigate this regional imbalance issue.

2. Fuel Diversity

FPL has also taken positive steps in 2004 to address the issue of fuel diversity in the FPL system. This has been accomplished in three key ways: through purchased power, proposed generation capacity additions, and pursuit of long-term Liquefied Natural Gas (LNG) supplies delivered to Florida.

First, FPL successfully negotiated and gained approval for a new purchased power agreement with Southern Company for the period 2010 to 2015. This new purchase adds 930 MW of capacity, of which 165 MW is coal-fired capacity that adds to system diversity. This purchase agreement also has strategic benefits for FPL's customers from a resource perspective in that it allows FPL to maintain access to the generation capabilities of the SERC region, which currently has a surplus of generation. This access allows FPL to purchase generation during certain periods at prices that may be lower than those of the generation assets FPL has under contract. Additionally, the time period of this purchase provides a bridge to a period where technological enhancements may offer cleaner, more efficient, and more diverse capacity alternatives than would be available in 2010.

Second, during 2004 FPL undertook a significant investigation and analysis of the benefits and risks of adding clean coal generation to the FPL system. A *Report on Clean Coal Generation* was presented to the Commission summarizing FPL's findings. These findings showed that, while there are uncertainties surrounding the costs of clean coal generation, significant cost and reliability benefits may be obtained by adding clean coal generation. The result is the proposed addition of two new supercritical pulverized coal units with advanced emission control technology, one each in 2012 and 2013. These clean coal capacity additions will help enhance FPL's fuel diversity by adding 1,700 MW of coal-based generation to the FPL system that would otherwise likely be provided by natural gas-fired units. FPL has initiated the process necessary to pursue the addition of these units.

Finally, FPL is evaluating proposals submitted in response to FPL's RFP requesting proposals to bring LNG to the Florida natural gas system under a long-term agreement. If cost-effective, LNG supply would add an additional source of natural gas to further support FPL's recent combined cycle unit additions.

In the future FPL will continue to identify and evaluate alternatives that may maintain or enhance fuel diversity in its capacity resource mix, including purchasing power from coal-fired facilities when such power becomes available. FPL also plans to maintain the ability to utilize fuel oil at those existing units that have that capability. FPL will continue to conduct reviews of technologies that may provide substantial fuel diversity in the future, such as nuclear power. Feasible opportunities to develop projects utilizing these technologies are currently beyond the planning horizon of this Site Plan.

III.D Demand Side Management (DSM)

1. FPL's currently approved DSM programs are summarized as follows:

Residential Conservation Service: This is an energy audit program designed to assist residential customers in understanding how to make their homes more energy-efficient through the installation of conservation measures/practices.

Residential Building Envelope: This program encourages the installation of energy-efficient ceiling insulation and reflective roofs in residential dwellings that utilize whole-house electric air conditioning.

Duct System Testing and Repair: This program encourages demand and energy conservation through the identification of air leaks in whole-house air conditioning duct systems and by the repair of these leaks by qualified contractors.

Residential Air Conditioning: This is a program to encourage customers to purchase higher efficiency central cooling and heating equipment.

Residential Load Management (On-Call): This program offers load control of major appliances/household equipment to residential customers, in exchange for monthly electric bill credits.

New Construction (BuildSmart): This program encourages the design and construction of energy-efficient homes that cost-effectively reduce coincident peak demand and energy consumption.

Residential Low Income Weatherization: This program addresses the needs of low-income housing retrofits by providing monetary incentives to various housing authorities, including weatherization agency providers (WAPS), and non-weatherization agency providers (non-WAPS). These incentives are used by the housing authorities to leverage their funds to increase the overall energy efficiency of the homes they are retrofitting.

Business Energy Evaluation: This program encourages energy efficiency in both new and existing commercial/industrial facilities by identifying DSM opportunities and providing recommendations to the customer.

Commercial/Industrial Heating, Ventilating, and Air Conditioning: This program encourages the use of high-efficiency heating, ventilation, and air conditioning (HVAC) systems in commercial/industrial facilities.

Commercial/Industrial Efficient Lighting: This program encourages the installation of energy-efficient lighting measures in commercial/industrial facilities.

Business Custom Incentive: This program encourages commercial/industrial customers to implement unique energy conservation measures or projects not covered by other FPL programs.

Commercial/Industrial Load Control: This program reduces peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages, in exchange for monthly electric bill credits. (This program was closed to new participants in 2000).

Commercial/Industrial Demand Reduction: This program, which started in 2002, is similar to the Commercial/Industrial Load Control program mentioned above in continuing the objective to reduce peak demand by controlling customer loads of 200 kW or greater during periods of extreme demand or capacity shortages in exchange for monthly electric bill credits.

Commercial/Industrial Building Envelope: This program encourages the installation of energy-efficient building envelope measures, such as roof/ceiling insulation and reflective roof coatings for commercial/industrial facilities.

Business On Call: This program offers load control of central air conditioning units to both small non–demand-billed and medium demand-billed commercial/industrial customers in exchange for monthly electric bill credits.

2. Research and Development

FPL continues to support research and development activities. Historically, FPL has performed extensive DSM research and development. FPL will continue such activities, not only through its Conservation Research and Development program, but also through individual research projects. These efforts will examine a wide variety of technologies that build on prior FPL research where applicable and will expand the research to new and promising technologies as they emerge.

Conservation Research and Development Program

FPL's Conservation Research and Development Program is designed to evaluate emerging conservation technologies to determine which are worthy of pursuing for program development and approval. FPL has researched a wide variety of technologies such as condenser coil cleaner and coating, ultraviolet lights for evaporator coils, Energy Recovery Ventilators (ERV), fuel cell demonstrations, CO_2 ventilation control, two-speed air handlers, and duct plenum repair. Many of the technologies examined have resulted in enhancements to existing programs or the development of new programs such as Residential New Construction, Commercial/Industrial Building Envelope, and Business On Call.

Green Power Pricing Research Project

Under this project, FPL is examining the feasibility of purchasing tradable renewable energy credits generated from new renewable resources including solar-powered technologies, biomass energy, landfill methane, wind energy, low impact hydroelectric energy, and/or other renewable sources. Residential customers who participate are charged higher premiums for purchasing the tradable renewable energy credits associated with electric energy generated by these sources.

Development of the Green Pricing program was completed and filed with the FPSC in August 2003. As part of this process, a supply contract was put into place that allows FPL to match supply with demand for green energy. Tradable renewable energy credits are used to supply the renewable benefits required of this project. The FPSC approved the program on December 2, 2003 with program implementation the first quarter of 2004. As of year-end 2004, FPL had over 10,000 project participants.

On Call Incentive Reduction Pilot

In March 2003, FPL received FPSC approval to perform a pilot for its On Call Program. Under the pilot FPL is offering to new participants a residential load control service similar to the On Call Program at a reduced incentive level. The offering of this pilot is allowing FPL to test its market research data and gauge whether FPL can repackage its current residential load control service, minimize customer attrition, achieve current goals for residential load control, and, ultimately, change On Call incentive levels without damaging FPL system reliability.

Business Green Energy Research Project

As mentioned above, FPL currently has a R&D project addressing residential customer acceptance of green energy. In an attempt to determine business customer acceptance of green pricing rates, FPL is investigating if it is feasible to design and implement a Green Energy Program that addresses these customer segments.

FPL's Summer MW Reduction Goals for DSM *

(At the Meter)

Year	Goal Cumulative Summer MW
2005	74.0
2006	141.7
2007	211.9
2008	287.2
2009	365.9
2010	447.9
2011	532.1
2012	618.8
2013	707.9
2014	801.7

Table III.D.1

* Table III.D.1 reflects FPL's new DSM Goals for 2005–2014 as approved by the Florida Public Service Commission in June, 2004. These annual cumulative values assume a 1/1/05 starting point.

III.E Generation Additions From Independent Power Producers

As previously mentioned in Section III.A, FPL has a number of new short-term, firm capacity purchases that extend through 2009. The capacity additions supplied by these purchases are summarized in Table I.D.1. Many of these purchases are from independent power producers.

Tables I.B.1 and Table I.B.2 present the capacity contributions from cogeneration/small power production facilities which are also included in FPL's resource planning work.

III.F Transmission Plan

The transmission plan will allow for the reliable delivery of the required capacity and energy for FPL's retail and wholesale customers. The following table presents FPL's proposed future additions to proposed transmission facilities and those that must be certified under the Transmission Line Siting Act.

List of Proposed Power Lines

(1) Line Ownership	(2) Terminals (To)	(3) Terminals (From)	(4) Line Length CKT. Miles	(5) Commercial In-Service Date (Mo/Yr)	(6) Nominal Voltage (kV)	(7) Capacity (MVA)
FPL	Collier	Orange River #3	54	12/05	230	759
FPL	St. Johns	Pringle	23	12/08	230	759

Table III.F.1

In addition, there will be transmission facilities needed to connect several of FPL's committed and projected capacity additions to the system transmission grid. These transmission facilities for the capacity additions at FPL's existing Manatee, Martin, Turkey Point, and West County Energy Center sites are described below.

Since the projected capacity additions for 2011 through 2013 are as-yet unsited, no transmission facilities information is provided. This information will be provided in future Site Plan documents once sites are selected.

III.F.1 Transmission Facilities at Manatee Unit # 3

The work required for the new capacity addition at Manatee with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's and one steam turbine.
2. Construct two string busses to connect the collectors and main switchyard.
3. Add five main step-up transformers (4-225MVA, 1-560MVA), one for each CT and one for the steam turbine.
4. Add two breakers in Bay # 6 to connect the collector bus at the Manatee switchyard.
5. Add two breakers in Bay # 5 at the Manatee switchyard to connect the other collector bus.
6. Add relays and other protective equipment.
7. Upgrade 13-230kV circuit breakers to 2 cycle Independent Pole breakers at Manatee switchyard.
8. Upgrade the existing line terminal at Johnson to 3000 Amps.
9. Expand site and relay vault for two new line terminals at Manatee switchyard.
10. Upgrade existing breaker at Ringling Sub to 3000 amps

II. Transmission:

1. Upgrade the Calusa-Charlotte 230kV transmission line to 1875 Amps.
2. Upgrade the Johnson-Manatee 230kV transmission line to 3000 Amps.
3. Upgrade the Manatee-Ringling # 3 230kV transmission line to 3000 Amps.
4. Upgrade the Charlotte-Fort Myers # 2 230kV transmission line to 1875 Amps.

III.F.2 Transmission Facilities at Martin Unit # 8

The work required for the new capacity addition at Martin (convert the existing two CT's to a new four-on-one combined cycle unit) with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing one collector buss with 3 breakers to connect the two CT's and one steam turbine.
2. Add one station service transformer in the existing CT yard.
3. Add three main step-up transformers (2-225 MVA, 560 MVA), one for each CT and one for the steam turbine.
4. Add two breakers in Bay # 3 to connect the collector bus in the main switchyard.
5. Add relays and other protective equipment.
6. Install phase reactors and string buss in main switchyard to limit fault current.
7. Add breaker in Bay # 7 for new Indiantown # 2 transmission line. Tap existing 69kV auto-transformer off east 230kV operating bus.
8. Add breaker in Bay # 3 at Indiantown Substation for Bridge line.
9. Create new Bay 4. Add 2 breakers for Indiantown-Martin #2 line at Indiantown Substation.
10. Create new Bay # 1 at Bridge Substation with 2 breakers. Add 2 breakers to convert station configuration from ring buss to a breaker and a half scheme.
11. Construct one string bus to connect the collector and main switchyard.

II. Transmission:

1. Construct 230kV Martin-Indiantown # 2 transmission line (Completed).
2. Construct 230kV Indiantown–Bridge # 2 transmission line (Completed).
3. Various OHGW replacements due to increased fault current.
4. Upgrade the Ranch-Homeland 230kV transmission line to 1600 Amps.

III.F.3 Transmission Facilities at Turkey Point Unit # 5

The work required for the new capacity addition at Turkey Point with the FPL grid is projected to be as follows:

II. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's and one steam turbine.
2. Construct two string busses to connect the collector busses and main switchyard.
3. Add five main step-up transformers (4-225MVA, 1-560 MVA), one for each CT and one for the steam turbine.
4. Add a new two breaker bay to connect the collector bus at the Turkey Point switchyard.
5. Add a second two breaker bay at the Turkey Point switchyard to connect the other collector bus.
6. Add relays and other protective equipment.
7. Expand site and relay vault for two new line terminals at Turkey Point switchyard.

II. Transmission:

1. Upgrade the Turkey Point-Galloway Tap 230kV transmission line section to 1418 Amps.
2. Upgrade the Turkey Point–McGregor-Florida City 230kV transmission line section to 1403 Amps.
3. Upgrade the Turkey Point-Miller 230kV transmission line section to 1356 Amps.
4. Upgrade the Miller-Killian 230kV transmission line section to 1315 Amps.

III.F.4 Transmission Facilities at West County Energy Center Unit # 1

The work required for the first new capacity addition projected to be added in 2009 at the West County Energy Center with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's and one steam turbine.
2. Construct two string busses to connect the collector busses and main switchyard.
3. Add five main step-up transformers (4-225 MVA, 1-560 MVA), one for each CT and one for the steam turbine.
4. Add a new Bay #4 with 3 breakers at the Corbett 230 kV main switchyard. Connect one string buss from the collector yard and relocate the Alva 230 kV terminal from Bay #3 to new Bay #4.
5. Connect second collector string buss to Bay #3.
6. Add relays and other protective equipment.
7. Expand substation and relay vault for two new line terminals at Corbett 230 kV switchyard.

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.F.5 Transmission Facilities at West County Energy Center Unit # 2

The work required for the second new capacity addition projected to be added in 2010 at West County Energy Center with the FPL grid is projected to be as follows:

I. Substation:

1. Build new collector yard containing two collector busses with 5 breakers to connect the four CT's and one steam turbine.
2. Construct two string busses to connect the collector busses and main switchyard.
3. Add five main step-up transformers (4-225 MVA, 1-560 MVA), one for each CT and one for the steam turbine.
4. Add a new bay with 3 breakers at the Corbett 500 kV main switchyard. Connect both string busses from the collector yard.
5. Add relays and other protective equipment.
6. Expand substation and relay vault for two new line terminals at Corbett 500 kV switchyard.

II. Transmission:

1. No upgrades expected to be necessary at this time.

III.G. Renewable Resources

FPL has been the leading Florida utility in examining ways to utilize renewable energy technologies to meet its customers' current and future needs. FPL has been involved since 1976 in renewable energy research and development and in facilitating the implementation of various technologies.

FPL assisted the Florida Solar Energy Center (FSEC) in the late 1970's in demonstrating the first residential solar photovoltaic (PV) system east of the Mississippi. This PV installation at FESC's Brevard County location was in operation for over 15 years and provided valuable information about PV performance capabilities on both a daily and annual basis in Florida. FPL later installed a second PV system at the FPL Flagami substation in Miami. This 10-Kilowatt (KW) system was placed into operation in 1984. (The system was removed in 1990 to make room for substation expansion after the testing of this PV installation was completed.)

For a number of years, FPL maintained a thin-film PV test facility located at the FPL Martin Plant Site. The FPL PV test facility was used to test new thin-film PV technologies and to identify design, equipment, or procedure changes necessary to accommodate direct current electricity from PV facilities into the FPL system. Although this testing has ended, the site is now the home for PV capacity which was installed as a result of FPL's recent Green Pricing effort (which is discussed on the following page).

In terms of utilizing renewable energy sources to meet its customers' needs, FPL initiated the first and only utility-sponsored conservation program in Florida designed to facilitate the implementation of solar technologies by its customers. FPL's Conservation Water Heating Program, first implemented in 1982, offered incentive payments to customers choosing solar water heaters. Before the program was ended (due to the fact that it was not cost-effective), FPL paid incentives to approximately 48,000 customers who installed solar water heaters.

In the mid-1980's, FPL introduced another renewable energy program. FPL's Passive Home Program was created in order to broadly disseminate information about passive solar building design techniques which are most applicable in Florida's climate. As part of this program, three Florida architectural firms created complete construction blueprints for 6 passive homes with the assistance of the FSEC and FPL. These designs and blueprints were available to customers at a low cost. During its existence, this program was popular and received a U.S. Department of Energy award for innovation. The program was eventually phased out due to a revision of the Florida Model Energy Building Code (Code). This revision was brought about in part by FPL's Passive Home Program. The revision incorporated into the Code one of the most significant passive design techniques highlighted in the program: radiant barrier insulation.

In early 1991, FPL received approval from the Florida Public Service Commission to conduct a research project to evaluate the feasibility of using small PV systems to directly power residential swimming pool pumps. This research project was completed with mixed results. Some of the performance problems identified in the test may be solvable, particularly when new pools are constructed. However, the high cost of PV, the significant percentage of sites with unacceptable shading, and various customer satisfaction issues remain as significant barriers to wide acceptance and use of this particular solar application.

More recently, FPL has analyzed the feasibility of encouraging utilization of PV in another, potentially much larger way. FPL's basic approach does not require all of its customers to bear PV's high cost, but allows customers who are interested in facilitating the use of renewable energy the means to do so. FPL's initial effort to implement this approach allowed customers to make voluntary contributions into a separate fund that FPL used to make PV purchases in bulk quantities. PV modules were then installed and delivered PV-generated electricity directly into the FPL grid. Thus, when sunlight is available, the PV-generated electricity displaces an equivalent amount of fossil fuel-generated electricity.

FPL's basic approach, which has been termed Green Pricing, was initially discussed with the FPSC in 1994. FPL's efforts to implement this approach were then formally presented to the FPSC as part of FPL's DSM Plan in 1995 and FPL received approval from the FPSC in 1997 to proceed. FPL began the effort in 1998 and received approximately $89,000 in contributions (that significantly exceeded the goal of $70,000). FPL purchased the PV modules and installed them at FPL's Martin Plant site.

FPL initiated two new renewable efforts in 2000. FPL's first new initiative in 2000 was the Green Energy Project. The objectives of this Project were to: determine customer interest in an on–going renewable energy program, determine their price responsiveness and views on the different renewable technologies, and identify potential renewable energy supply sources that would meet the forecasted customer demand for this type of product. FPL both conducted customer research and issued a Request for Proposals (RFP) in 2001 to solicit proposals to potentially supply energy only (MWH) from new renewable sources. This Project formed the basis for FPL's existing Green Power Pricing Research Project , and then led to FPL's Business Green Energy Research Project, that are discussed in Section III.D.2.

The second effort initiated in 2000 was FPL's Photovoltaic Research, Development, and Education Project. This demonstration project's objectives were to: increase the public awareness of roof tile PV technologies, provide data to determine the durability of this technology and its impact on FPL's electric system, collect demand and energy data to better understand the coincidence between PV roof tile system output and FPL's system peaks (as well as the total annual energy capabilities of roof tile PV systems), and assess the homeowner's financial benefits and costs of PV roof tile systems. This project was completed in 2003.

Finally, FPL has also facilitated renewable energy projects (facilities which burn bagasse, waste wood, municipal waste, etc.). Firm capacity and energy and as-available energy have been purchased by FPL from these developers. (Please refer to Tables I.B.1 and I.B.2).

III.H FPL's Fuel Mix and Fuel Price Forecasts

1. FPL's Fuel Mix

Until the mid-1980's, FPL relied primarily on a combination of oil, natural gas, and nuclear energy to generate electricity with significant reliance on oil–fired generation. In the early 1980's FPL began to purchase "coal-by-wire." In 1987, coal was first added to the fuel mix through FPL's partial ownership and additional purchases from the St. Johns River Power Park (SJRPP). This allowed FPL to meet its customers' energy needs with a more diversified mix of energy sources. Additional coal resources were added with the partial acquisition (76%) of Scherer Unit # 4 in 1989. Starting in 1997, petroleum coke was added to the fuel mix as a blend stock with coal at SJRPP.

The trend in recent years has been a steady increase in the amount of natural gas that is used by FPL to provide electricity due, in part, to the introduction of highly efficient and cost-effective combined cycle generating units. This planning document shows a slowing of that trend as FPL recognizes that adding natural gas-fired additions exclusively would, in the long term, create an unbalanced generation portfolio. FPL does project the addition of new gas-fired units in 2009 and 2010, which is a necessity given the longer lead times associated with the addition of coal-fired generation.

FPL's future resource planning work will remain focused on identifying and evaluating alternatives that would maintain or enhance FPL's long-term fuel diversity. These fuel diversity-enhancing alternatives may include: the purchase of power from new coal-based facilities, obtaining access to diversified sources of natural gas such as LNG, and preserving FPL's ability to utilize fuel oil at its existing units. The evaluation of the feasibility and cost-effectiveness of these, and other possible alternatives, will be an ongoing part of future planning cycles.

FPL's current use of various fuels to supply energy to customers, plus a projection of this "fuel mix" through 2014 based on the resource plan presented in this document, is presented in Schedules 5, 6.1, and 6.2 later in this chapter.

2. Fuel Price Forecasts

FPL's long-term oil price forecast assumes that worldwide demand for petroleum products will grow moderately throughout the planning horizon. Non-OPEC crude oil supply is projected to increase as new and improved drilling technology and seismic information will reduce the cost of producing crude oil and increase both recoveries from existing fields and new discoveries. However, the rate of increase in non-OPEC supply is projected to be slower than that of petroleum demand, resulting in an increase in OPEC's market share throughout the planning horizon. As OPEC gains market share, prices for crude oil and petroleum products are projected to increase.

FPL's natural gas price forecast assumes that domestic demand for natural gas will grow throughout the planning horizon, primarily due to increased requirements for electric generation. Domestic natural gas production will slowly decline as new and improved drilling technology and seismic information and resulting new finds will only reduce the projected rate of decline in the overall domestic resource base. The rate of decline in domestic natural gas production is projected to be more than offset by the anticipated increase in U.S. imports from Canada during the next decade, with the development of the MacKenzie Delta region, and the continued increase in re-gasified Liquefied Natural Gas (LNG) imports over the planning horizon. Further enhancement in domestic supply is assumed with the development and delivery of the proven natural gas reserves on the North Slope of Alaska sometime in the next decade.

As demand for natural gas in Florida grows, it is anticipated that the Gulfstream pipeline will fill existing capacity, and along with the Florida Gas Transmission (FGT) pipeline system, expand beyond current capacity to meet the growing requirements of the State of Florida. When coupled with the potential for re-gasified LNG (natural gas) imports directly into Florida, there should be sufficient natural gas deliverability for FPL's customers and the State of Florida's continued needs.

FPL issued an RFP in August 2004 for between 400,000 and 600,000 MMBTU/day of re-gasified LNG supplies, for a minimum term of fifteen (15) years and a maximum term of twenty-five (25) years, with a start date between January 1, 2007 through December 31, 2010. FPL is in the process of evaluating the proposals received in the RFP process and has set a target date of June 1, 2005 for completion of Definitive Agreements subject to a few external approvals. Although this RFP is not in response to a specific need for natural gas supplies, the potential completion of the transaction contemplated by the RFP would diversify and supplement FPL's natural gas supplies from the Gulf of Mexico region.

FPL's coal price forecast assumes an ample supply of domestic coal, and the availability of imported coal, to meet a gradual but steady increase in U.S. demand in the electric generation sector over the planning horizon. The coal price forecast for FPL's existing coal plants at SJRPP and Plant Scherer assume the continuation of the existing mine-mouth and transportation contracts until expiration, along with the purchase of spot coal, to meet generation requirements. FPL's petroleum coke price forecast assumes that the petroleum industry will continue to add cokers in the U.S., as well as in the Caribbean Basin, in order to maximize refinery production of light products. This trend will continue to result in sufficient availability of petroleum coke, at delivered prices significantly below delivered coal prices, to support a gradual, but steady growth in the demand for petroleum coke in the U.S. electric utility industry.

In order to support the proposed coal requirements in the 2012 and 2013 time period, FPL is currently exploring the opportunities for a competitive coal and petroleum coke delivery system. This effort includes the opportunity for competing rail service from Central Appalachia to Florida, a waterborne receiving facility on both the east and west coast of Florida, and competing rail service from these potential ports to the solid fuel site. A highly competitive coal and petroleum coke delivery network is essential to ensure both the lowest cost fuel supply to FPL's customers.

Schedule 5
Fuel Requirements 1/

			Actual 2/		Forecasted									
	Fuel Requirements	Units	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014
(1)	Nuclear	Trillion BTU	257	252	245	254	246	260	255	254	259	256	254	259
(2)	Coal	1,000 TON	3,402	3,319	3,397	3,455	3,597	3,523	3,670	3,430	3,670	4,852	7,503	8,404
(3)	Residual (FO6)- Total	1,000 BBL	32,103	31,250	29,627	33,005	22,926	22,702	22,373	20,586	22,087	21,289	19,735	21,941
(4)	Steam	1,000 BBL	32,103	31,250	29,827	33,005	22,926	22,702	22,373	20,586	22,087	21,289	19,735	21,941

1/ Capacity additions and changes projected to be in-service by June 1st are considered to be available to meet Summer peak loads which are forecasted to occur during August of the year indicated. All values are Summer net MW. The value shown for FPL's unit capability for the Summer of 2005 is an updated projection from the value used in FPL's 2004 analyses.

2/ Total Capacity Available = Col.(2) + Col.(3) - Col.(4) + Col.(5).

3/ These forecasted values reflect the Most Likely forecast without DSM.

4/ The DSM MW shown represent cumulative load management capability plus incremental conservation from 1/2004-on for use with the 2004 load forecast. They are not included in total additional resources but reduce the peak load upon which Reserve Margin calculations are based.

5/ Margin (%) Before Maintenance = Col.(10) / Col.(9)

6/ Margin (%) After Maintenance = Col.(13) / Col.(9)

Note 1: The Winter Total MW value consists of all generation additions and changes achieved by January. The Summer Total MW value consists of all generation additions and changes achieved by June. All other MW will be picked up in the following year.

Note 2: Capacity additions/changes shown for 2004 reflect changes/additions from values shown in Schedule 1.

Schedule 9
Status Report and Specifications of Proposed Generating Facilities

(1) **Plant Name and Unit Number:** Martin Combustion Turbine Conversion to Combined Cycle Unit # 8

(2) **Capacity**
a. Summer 787 MW Incremental (1107 MW Total)
b. Winter 835 MW Incremental (1197 MW Total)

(3) **Technology Type:** Combined Cycle

(4) **Anticipated Construction Timing**
a. Field construction start-date: 2003
b. Commercial In-service date: 2005

(5) **Fuel**
a. Primary Fuel: Natural Gas
b. Alternate Fuel: Distillate

(6) **Air Pollution and Control Strategy:** Natural Gas, Dry Low NO_x Combustors, SCR, 0.05% S. Distillate, & Water Injection on Distillate

(7) **Cooling Method:** Cooling Tower

(8) **Total Site Area:** 11,300 Acres

(9) **Construction Status:** V (Under Construction >= 50% Complete)

The proposed new West County Energy Center CC Unit # 1 does not require any "new" transmission lines.

Schedule 10
Status Report and Specifications of Proposed Transmission Lines

West County Energy Center 2 Combined Cycle Unit # 2

The proposed new West County Energy Center CC Unit # 2 does not require any "new" transmission lines.

CHAPTER IV

Environmental and Land Use Information

(This page is left intentionally blank.)

IV. Environmental and Land Use Information

IV.A Protection of the Environment

FPL operates in a sensitive, temperate/sub-tropical environment containing a number of distinct ecosystems with many endangered plant and animal species. Population growth in its service area is continuing, which heightens competition for air, land, and water resources that are necessary to meet the increased demand for generation, transmission, and distribution of electricity. At the same time, residents and tourists want unspoiled natural amenities, and the general public has an expectation that large corporations such as FPL will conduct their business in an environmentally responsible manner.

FPL has been recognized for many years as one of the leaders among utilities for its commitment to the environment. Many outside organizations have heralded its environmental leadership. In 2004 FPL Group earned a first place ranking among U.S. power companies, and second globally, in a report from the World Wildlife Fund for voluntary commitments to limit CO_2 emissions. This commitment was made to support initiatives to better manage utility impacts on global warming through use of greenhouse gas emission reductions and improvements in energy efficiency. The report stated that this was "primarily due to the company's leadership in developing wind energy and their commitment to dramatically improve their efficiency". FPL was also recently ranked first out of 28 major electric utilities surveyed in an environmental assessment conducted by Innovest, an independent advisory group. In recognition of its success in executing a strategy to become a clean energy provider harnessing primarily clean and renewable fuels while also boosting shareholder value, FPL Group, Inc. was named in June 2003 as the winner of the Edison Award, the electric power industry's highest honor by the Edison Electric Institute.

FPL was awarded Edison Electric Institute's National Land Management Award for its stewardship of 25,000 acres surrounding its Turkey Point Plant. FPL won the Council for Sustainable Florida's award for its sea turtle conservation and education programs at its St. Lucie Plant. In 2001, FPL was awarded the 2001 Waste Reduction and Pollution Prevention Award from the Solid Waste Association of North America. FPL received the 2001 Program Champion Award from the Environmental Protection Agency's Wastewise Program. The Florida

Department of Environmental Protection named FPL a "Partner for Ecosystem Protection" for its emission-reducing "repowering" projects at its Fort Myers and Sanford Plants. Finally, FPL has been recognized by numerous federal and state agencies for its innovative endangered species programs which include such species as manatees, crocodiles, and sea turtles.

IV.B FPL's Environmental Statement

To reaffirm its commitment to conduct business in an environmentally responsible manner, FPL developed an Environmental Statement in 1992 to clearly define the Company's position. This statement reflects how FPL incorporates environmental values into all aspects of the Company's activities and serves as a framework for new environmental initiatives throughout the Company. The FPL environmental statement further establishes a long-term direction of environmental initiatives throughout the Company. FPL's Environmental Statement is:

> It is the Company's intent to continue to conduct its business in an environmentally responsible manner. Accordingly, Florida Power & Light Company will:
>
> - Comply with the spirit and intent, as well as the letter of, environmental laws, regulations, and standards.
> - Incorporate environmental protection and stewardship as an integral part of the design, construction, operation, and maintenance of our facilities.
> - Encourage the wise use of energy to minimize the impact on the environment.
> - Communicate effectively on environmental issues.
> - Conduct periodic self-evaluations, report performance, and take appropriate actions.

IV.C Environmental Management

In order to implement the Environmental Statement, FPL established an environmental management system to direct and control the fulfillment of the organization's environmental responsibilities. A key component of the system is an Environmental Assurance Program that is discussed below. Other components include: executive management support and commitment, written environmental policies and procedures, delineation of organizational responsibilities and individual accountabilities, allocation of appropriate resources for environmental compliance management (which includes reporting and corrective action when non-compliance occurs), environmental incident/emergency response, environmental risk assessment/management, environmental regulatory development and tracking, and environmental management information systems.

IV.D Environmental Assurance Program

FPL's Environmental Assurance Program consists of activities which are designed to evaluate environmental performance, verify compliance with Company policy as well as with legal and regulatory requirements, and communicate results to corporate management. The principal mechanism for pursuing environmental assurance is the environmental audit. An environmental audit may be defined as a management tool comprising a systematic, documented, periodic, and objective evaluation of the performance of the organization and of the specific management systems and equipment designed to protect the environment. The environmental audit's primary objectives are to: facilitate management control of environmental practices and assess compliance with existing environmental regulatory requirements and Company policies.

IV.E Environmental Communication and Facilitation

FPL is involved in many efforts to enhance environmental protection through the facilitation of environmental awareness and in public education. Some of FPL's 2004 environmental outreach activities are noted in Table IV.E.1.

Activity	# of Participants
Visitors to Energy Encounter	20,000
Visitors to Manatee Park	150,000
Number of "visits" to FPL' s Environmental Website	195,000
Number of pieces of environmental literature distributed	>110,000

Table IV.E.1

(All numbers are approximations.)

IV.F Preferred and Potential Sites

Based upon its projection of future resource needs, FPL has identified preferred and potential sites for future generation additions. These preferred and potential sites are discussed in separate sections below.

IV.F.1 Preferred Sites

FPL identifies four preferred sites in this Site Plan: the existing Martin plant site, the existing Manatee plant site, the existing Turkey Point plant site, and the West County Energy Center which is adjacent to the existing FPL Corbett substation in Palm Beach County. Three of these four sites are the locations for capacity additions that FPL is committed to make during the 2005-2007 period. The fourth site is the projected location for capacity additions FPL is proposing to make in 2009 and 2010.

The capacity additions at the Martin, Manatee, and Turkey Point sites have been approved by the FPSC. The Martin and Manatee capacity additions will come in-service in mid-2005 and the Turkey Point capacity addition will come in-service in mid-2007. The discussion of capacity additions at the West County Energy Center represent FPL's current projection of how it will meet its capacity needs for 2009 and 2010.

The four preferred sites are discussed below.

Preferred Site # 1: Manatee Plant, Manatee County

The site is located in unincorporated north central Manatee County approximately 2.5 miles south of the Hillsborough-Manatee County line. It is 5 miles east of Parrish, Florida and is approximately 5 miles east of U.S. Highway 301 and 9.5 miles east of Interstate 75 (I-75). State Road (SR) 62 is about 0.5 miles south of the site. Saffold Road marks the eastern boundary of the site.

FPL's Manatee Plant occupies a portion of the approximately 9,500 acre Manatee Site which is wholly owned by FPL. The site includes a 4,000 acre cooling pond including the dike area. The existing approximately 1,590 MW (Summer) of generating capacity is made up of two steam units (Units # 1 and # 2) which have been in-service since 1976 and 1977 respectively. These units burn both fuel oil (residual) with a maximum sulfur content of 1 percent and natural gas. Natural gas may be fired singly or in combination with fuel oil. A recent agreement between FPL and Gulfstream Natural Gas Systems (Gulfstream), and the nearby Florida Gas Transmission (FGT) system, provides two natural gas sources for these units.

Additional generating capacity is being added to the site for operation beginning in 2005 to meet projected FPL system capacity needs. One unit consisting of four new combustion turbines (CT's), four new heat recovery steam generators (HRSG's), and a new steam turbine generator are scheduled for in-service operation beginning in June 2005. The four new CT's, HRSG's, and steam turbine will ultimately be operating in combined cycle (CC) configuration. This new CC unit will add 1,107 MW (Summer) and 1,197 MW (Winter) capability to the site. This new CC Unit will be designated as Manatee Unit # 3.

Unit # 3 is located west of the existing generating Units # 1 and # 2. The location of the new combined cycle Unit # 3 at the Manatee Plant site and the selection of the highly efficient combined cycle technology (firing natural gas) will maximize the beneficial use of the site while minimizing environmental and land use impacts otherwise associated with the development of a new generating plant of this capacity. The Manatee site has been previously listed as a preferred or potential site in FPL Site Plans and continues to be a potential site for future capacity additions, if needed in the future.

a. and b. <u>U.S. Geological Survey (USGS) Map and Proposed Facilities Layout</u>

A map indicating the Manatee plant site showing the general layout of the facilities and a map indicating the land use of the site are found at the end of this chapter.

c. <u>Map of Site and Adjacent Areas</u>

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 4,000 acre cooling pond. Manatee Units # 1 and # 2 will not be affected by the addition of Unit # 3. The area for Unit # 3 is expected to comprise approximately 73 acres. The site and surrounding land uses are almost exclusively agriculture with the exception of the Willow Shores residential area located northwest of the Manatee Plant site. Individual homes are located in the larger of two out parcels within the Manatee Plant site along SR 62 at the northeast corner of the site. The vast majority of the Manatee Plant site was re-designated from Agricultural/Rural to Major Public/Semi Public (1) (P/SP) land use category by the Manatee County Commission on November 19, 2002 with the approval of Ordinance 02-13. Electric generating plants are specifically allowed in the P/SP category in accordance with the Manatee County Local Government Comprehensive Plan and Land Development Regulation Act, Chapter 163, Part II, Florida Statutes (FS).

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

There are no incorporated areas within 5 miles of the Manatee Plant site. Unincorporated communities in the area include Willow, located about 2 miles north of the Manatee Plant; Parrish, located about 5 miles southwest of the plant; and, in Hillsborough County, Sundance, located 3 miles northwest of the plant; Sun City Center, located 7 miles north of the plant; and Wimauma, located 8 miles northeast of the plant.

The Manatee Plant site includes areas of improved pasture with forested land southeast of the project area. This forested area is comprised of flat woods and oak habitat. The western side of the Manatee Plant site is currently used for agriculture. There are also wetlands to the southeast containing wet pine flat woods mixed with dry pine flat woods. There will not be any disturbance of existing wetlands associated with this project.

2. Listed Species

Construction and operation of the new Unit # 3 at the site is not expected to affect any rare, endangered, or threatened species. The majority of the site is cleared, grassed, and periodically mowed. The project area has been significantly altered by the construction and operation of the existing plant facilities, and, as a result, wildlife utilization of this area is minimal. Common wading birds utilizing the plant site outside of the project area include the great blue heron, little blue heron, great egret, snowy egret, and the white ibis. Typical mammals found in the habitats surrounding the project area are common bobcat, raccoon, deer, feral hog, opossum, armadillo, skunk, and gray squirrel. Avian species observed in the vicinity of the project include bald eagles, a variety of songbirds, red-shouldered hawks, and marsh hawks.

3. Natural Resources of Regional Significance Status

There are no county, State or Federal designated areas located within one mile of the plant site. The construction and operation of Manatee Unit # 3 is not expected to have any adverse impacts on parks, recreation areas, or environmentally sensitive lands that are associated with the Little Manatee River within a 5-mile radius of the project site. These lands include: Little Manatee River State Recreation Area, Little Manatee River State Canoe Trail, Florida Gulf Coast Railroad Museum, Cockroach Bay Aquatic Preserve, Critical Manatee Habitat, South Hillsborough Wildlife Corridor, Hillsborough County Environmental Lands Acquisition and Protection Program Parcels, and Save Our River-Little Manatee River.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

Manatee Unit # 3 consists of the addition of four new combustion turbines, four HRSG's, and one new steam turbine generator in combined cycle mode in a 4x1 configuration. Manatee Unit # 3 is scheduled to begin operation in mid-2005. Natural gas, delivered via pipeline, will be the sole fuel for this unit.

Mitigation aspects of Manatee Unit # 3 include: the capture and reuse of plant process water and rainwater, the use of combustion technology that is very efficient and low in air pollutant emissions, plus pollution control technology (dry-low NO_x burners and selected catalytic reduction equipment).

g. Local Government Future Land Use Designations

As mentioned above, the Local Government Future Land Use Plan is consistent with the existing Designated uses of the Manatee Plant Site as major portions of the site are designated as Major Public/Semi Public (1) – P/PS/. Electric generating plants are specifically allowed in this land use category.

h. Site Selection Criteria and Process

The Manatee plant site was selected due to consideration of various factors including system load and economics. The availability of a natural gas pipeline was also a major factor in the selection of the Manatee site for the new 4x1 CC unit. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues.

i. Water Resources

The available surface water source is the Little Manatee River which supplies makeup water for the 4,000-acre cooling pond. Plant process and service water requirements are currently supplied by the cooling pond. There are three wells in the Floridan Aquifer that are reserved for standby purposes.

j. Geological Features of Site and Adjacent Areas

Manatee County has three physiographic provinces: the Gulf Coast Lowlands, the DeSoto Plains, and the Polk Upland. The Manatee Plant is situated on the boundary of the DeSoto Plains and the Gulf Coast Lowland provinces. The geology underlying the Manatee Plant consists of unconsolidated sediments comprised of sand, clay silt, marl shell, limestone, and phosphorite (terrace deposits) from the Pleistocene age to recent. Undifferentiated deposits comprised of sand and clay are generally described to be less than 25 feet thick. Underlying the differentiated materials are the Miocene Hawthorn Formation, the Tampa Member, the Suwanee Limestone of the Oligocene age, the Ocala Limestone of the Eocene Age, the Avon Park Formation, the Oldsmar Formation of the Eocene age, and the Cedar Key Formation of the Paleocene age.

The major hydro-geologic units that exist in the vicinity of the site include, in descending order: the surficial aquifer system, the intermediate aquifer system, and the Upper Floridan aquifer. The surficial aquifer system is generally unconfined in Manatee County and consists of Quaternary deposits of predominately marine and non-marine quartz sand, clayey sand, shell, shelly marl, phosphorite, and occasional stringersmarl and limestone. In the vicinity of the site the surficial sediments are approximately 25 feet thick.

k. Projected Water Quantities for Various Uses

The estimated additional quantity of water for industrial processing is estimated to be 150 gallons per minute (gpm) and provides plant process and service water. FPL operates on-site water treatment systems for each of these uses. Water quantities for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l. Water Supply Sources by Type

Manatee Unit # 3 will utilize the existing on-site cooling pond as its source of cooling water. The cooling pond operates as a "closed cycle" system; any makeup water is provided from the Little Manatee River to replace net evaporation and seepage losses from the pond. These makeup needs are within the existing agreement between FPL and the Southwest Florida Water Management District (SWFWMD). There are three wells currently on reserve (stand-by) that are in the Floridan Aquifer.

m. Water Conservation Strategies Under Consideration

Available water including non-contact storm water, treated industrial wastewater, treated sanitary wastewater, and recovered service water are captured and returned to the cooling pond. Storm water from the equipment areas is also treated and returned to the cooling pond.

n. Water Discharges and Pollution Control

The Manatee Plant utilizes a Best Management Practices (BMP) plan and a Spill Prevention, Control, and Countermeasure (SPCC) plan to assist in the control of inadvertent release of pollutants. Storm water runoff is collected and routed to detention ponds. Construction activities are managed so that equipment maintenance and fueling are performed in designated areas so that, in the event of a spill or release of any contaminant, impacts to any surface water or the cooling pond are minimized.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by fuel delivery services and facilities for residual, low sulfur (1 percent) fuel oil and, most recently, natural gas as an alternate fuel for existing Units # 1 and # 2. The Unit # 3 addition will be fueled solely by natural gas that could be supplied by either Gulfstream or FGT as previously discussed.

p. Air Emissions and Control Systems

The addition of natural gas as a permitted fuel for existing Units # 1 and # 2 is expected to lower overall emissions during periods when natural gas, instead of fuel oil, is used. In addition, a NO_x reduction technology, re-burn, has been approved for installation on Units # 1 and # 2 and are being installed.

The use of natural gas and combustion controls will minimize air emissions from Unit # 3 and ensure compliance with applicable emission limiting standards. Using natural gas minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of carbon monoxide and volatile organic compounds. NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. The design of Manatee Unit # 3 incorporates features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise emissions from the project are not anticipated to be significantly different from the current levels at the existing plant. Similar natural gas-fired facilities in Broward and Martin Counties have been constructed and operated without exceeding allowable noise levels.

r. Status of Applications

FPL filed the Site Certification Application (SCA) for Manatee Unit # 3 with the Florida Department of Environmental Protection (FDEP) on February 20, 2002 and received approval and Site Certification by the Governor and Cabinet in April 2003. FPL acquired all permits needed and commenced construction in May 2003. Modifications to operating permits will be pursued as necessary.

Preferred Site # 2: Martin Plant, Martin County

The Martin site is located approximately 40 miles northwest of West Palm Beach, 5 miles east of Lake Okeechobee, and 7 miles northwest of Indiantown in Martin County, Florida. The site is bounded on the west by the Florida East Coast Railway (FEC) and the adjacent South Florida Water Management District

(SFWMD) L-65 Canal, on the south by the St. Lucie Canal (C-44 or Okeechobee Waterway), and on the northeast by SR 710 and the adjacent CSX Railroad. The Martin site was identified in 1987 as a preferred location for development of coal gasification/combined cycle electric generation facilities and subsequent FPL Site Plans have continued to identify this site as a preferred site.

The existing 2,900 (approximate) MW (Summer) of generating capacity at FPL's Martin site occupies a portion of the approximately 11,300 acres that are wholly owned by FPL. The generating capacity is made up of two steam units (Units # 1 and # 2), plus two combined cycle units (Units # 3 and # 4), and two combustion turbine units (Units # 8a and # 8b) that are being converted to combined cycle through the construction of two additional combustion turbines (Units # 8c and # 8d), four Heat Recovery Steam Generators (HRSG's), and a steam turbine. The new combined cycle unit will be named Martin Unit # 8. The site includes a 6,800 acre cooling pond (6,500 acres of water surface and 300 acres of dike area) and approximately 300 acres for the existing power plant units and related facilities.

Martin Unit # 8 is scheduled to be in-service in mid-2005 and will add approximately 790 MW of capacity. The Martin site has been previously approved for the development of solid fuel generating units and has also been listed as a preferred or potential site in previous FPL Site Plans for combined cycle and simple cycle generation options. The Martin site continues to be a potential option for additional generating units when needed in the future.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the Martin plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a 6,800-acre cooling pond. The existing power plant facilities are located on approximately 300 acres. To the east of the power plant there is an area of mixed pine flat wood with a scattering of small wetlands. To the north of the cooling pond there is a 1,200-acre area which has been set aside as a mitigation area. There is a peninsula of wetland forest on the West Side of the reservoir that is named the Barley Barber Swamp. The Barley Barber Swap encompasses 400 acres and is preserved as a natural area. There is also a 10-kilowatt (kW) photovoltaic energy facility at the south end of this site.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

As noted above, the Barley Barber Swamp is located on the site. There is also a 1,200-acre mitigation area in the northern area of the site where wetlands and uplands have been preserved. Along the south and west sides of the cooling pond is an area where the vegetation has been maintained in its natural state in order to serve as a wildlife corridor. There are pine flat woods and small-scattered wetlands to the east of the plant.

2. Listed Species

Construction and operation of a new unit at the site is not expected to affect any rare, endangered, or threatened species. There are two active Bald Eagle (*Haliaeetus leucocephalus*: Federal- and State-listed as Threatened) nests that have been on the site for many years. The Florida Natural Areas Inventory (FNAI) database notes a record of Eastern Indigo Snakes (*Drymachon coralis coupert*, which are Federal- and State-listed as threatened) in the Barley Barber Swamp. A number of other Bald Eagle nests and sightings of Eastern Indigo Snakes are reported by the FNAI database within a two-mile radius of the site. Infrequent sightings of Florida Panther have been made in the vicinity of the site area.

3. Natural Resources of Regional Significance Status

The Treasure Coast Regional Planning Council lists the "FPL Preserve", including the Barley Barber Swamp, as a Significant Regional Facility. Natural communities such as uplands and wetlands are also generically listed as Resources of Regional Significance.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

Martin Unit # 8 consists of the addition of two new CT's, four new HRSG's, and a new steam turbine to the two existing CT's, resulting in a 4x1 configuration combined cycle unit. This unit is scheduled to be in-service in mid-2005. Natural gas delivered via pipeline is the primary fuel type for this unit (with light oil serving as a backup fuel). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation aspects of Martin Unit # 8 include the capture and reuse of plant process water and rainwater, plus the use of cooling towers.

g. Local Government Future Land Use Designations

Local government future land use designation for the site is "Public Utilities". Designations for the surrounding area are primarily "Agricultural". There are also limited areas of "Agricultural Ranchette", "Industrial", and a small "Commercial" area designation. To the southeast of the property, fronting on the St. Lucie Canal, is an area designated for "Public Conservation".

h. Site Selection Criteria and Process

The Martin plant site has been selected due to consideration of various factors including system load and economics. Environmental issues were not a deciding factor since this site does not exhibit significant environmental sensitivity or other environmental issues.

i. Water Resources

Surface water resources currently used at the Martin facility include the cooling pond which takes its water from the St. Lucie canal. The available ground water resource is the surficial aquifer system which is used as a source of potable and service water. Both of these sources will be used.

j. Geological Features of Site and Adjacent Areas

FPL's Martin site is underlain by approximately 13,000 feet of sedimentary rock strata. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily marine bin origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The deepest formation in Martin County on which significant published data are available is the Eocene Age Avon Park. Limited information is available from wells penetrating the underlying Lake City formation. The published information on the sediments comprising the formations below the Avon Park Limestone in western Martin County is based on projections from deep wells in Okeechobee, St. Lucie, and Palm Beach Counties.

k. Projected Water Quantities for Various Uses

The estimated additional quantity of water required for industrial processing is 130 gallons per minute (gpm) for uses such as process water and service water. FPL operates on-site water treatment systems for each of these uses. Cooling water for Unit # 8 will be cycled through the addition of cooling towers. Makeup water for the pond is taken from the St. Lucie canal. The current makeup water quantity to the cooling pond (approximately 4,800 gpm) is expected to be adequate for the operation of Unit # 8. Water quantities needed for other uses such as irrigation and potable water are estimated to be approximately 5 gpm.

l. Water Supply Sources by Type

Martin Unit # 8 will utilize the existing on-site cooling pond as the source of cooling water for the cooling towers and as a heat sink for the dissipation of cooling water heat. The cooling towers will also act as a heat sink for the Unit # 8 process water. The cooling pond operates as a "closed cycle" system in which heated water from the generating units loses its heat as it is circulated within the pond and back around to the plant intake. Water is also collected in a seepage ditch surrounding the cooling pond and is then pumped back into the cooling pond. Makeup water to the pond is withdrawn from the St. Lucie canal as needed to replace net evaporation and seepage losses from the pond. Such needs will comply with the existing agreement between FPL and the South Florida Water Management District (SFWMD) regarding allocation of cooling water to the pond and with SFWMD's regulations for consumptive water use.

The existing water treatment system at the plant, which provides treated water for use in the Unit # 1 and # 2 boilers, as well as for the HRSG's associated with Units # 3 and # 4, will be used to provide treated water for Unit # 8.

m. Water Conservation Strategies Under Consideration

The entire plant site captures and reuses process water whenever feasible and manages storm water in such a manner so as to recharge the surficial aquifer.

n. Water Discharges and Pollution Control

Heated water discharges will be dissipated in the cooling tower and cooling pond. Non-point source discharges are not an issue since there are none at this facility. Industrial discharges will be minimized by treating and recycling equipment wash water, boiler blowdown water, and equipment area runoff. Storm water runoff is collected and used to recharge the surficial aquifer via a storm water management system. Design elements have been included to capture suspended sediments. Facility permits mandate various sampling and testing activities that provide indications of any pollutant discharges. The facility employs a Best Management Practices (BMP) plan and Spill

Prevention, Control, and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by multiple fuel delivery facilities including the installation of a new pipeline. Gulfstream has constructed the new pipeline which provides an alternative fuel supply to the existing Florida Gas Transmission natural gas pipeline. The site is also served by an oil pipeline that serves the existing steam boilers. Distillate is received by truck and stored in above-ground storage tanks. An additional above-ground storage tank was constructed to serve the backup distillate fuel needs of Unit # 8.

p. Air Emissions and Control Systems

FPL's Unit # 8 is subject to "New Source Review" under Federal and State Prevention of Significant Deterioration (PSD) regulations. This review requires these units to meet New Source Performance Standards (NSPS) and that Best Available Control Technology (BACT) be selected to control emissions of those pollutants emitted in excess of applicable PSD significant emission rates. The primary purpose of BACT analysis is to minimize the allowable increases in air pollutants taking into account energy, environmental, and economic impacts. This process provides for the potential for future economic growth without significantly degrading air quality.

The use of natural gas as the primary fuel, plus combustion controls, will minimize air emissions from Unit # 8 and ensure compliance with applicable emission limiting standards. Using natural gas minimizes emissions of sulfur dioxide (SO_2), particulate matter, and other fuel-bound contaminates. Combustion controls similarly minimize the formation of carbon monoxide and volatile organic compounds. NO_x emissions will be controlled using dry-low NO_x combustion technology and selective catalytic reduction (SCR). These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. The design of Unit # 8 incorporates features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

Noise emissions from the project are not anticipated to be significantly different from the current levels at the existing plant. Similar natural gas-fired facilities in Broward and Martin Counties have been constructed and operated without exceeding allowable noise levels

r. Status of Applications

An SCA was filed in December 1989 for the construction and operation of the Martin Coal Gasification/Combined Cycle project under the Florida Electrical Power Plant Siting Act. In order to convert the two CT's from simple cycle to (4X1) CC configuration (Unit # 8), a modification to the Site Certification was required. FPL filed the SCA modification on February 1, 2002 with the FDEP. Approval and Site Certification was issued by the Governor and Cabinet in April 2003. FPL acquired all construction permits and commenced construction in May 2003. Modifications to operating permits will be pursued as necessary.

Preferred Site # 3: Turkey Point Plant, Miami-Dade County

The Turkey Point Plant site is located on the west side of Biscayne Bay, 25 miles south of Miami. The site is directly on the shoreline of Biscayne Bay and is geographically located approximately 9 miles east of Florida City on Palm Drive. Public access to the plant site is limited due to the nuclear units located there. The land surrounding the site is owned by FPL and acts as a buffer zone. The site is comprised of two nuclear units and two conventional boiler, fossil units, the cooling canals, an FPL-maintained natural wildlife area, and wetlands that have been set aside as the Everglades Mitigation Bank (EMB).

Units # 1 and # 2 are fossil fuel generating plants with approximate generating capacity of 400 MW each. Unit # 1 was completed in 1967 and Unit # 2 in 1968. Turkey Point also has five diesel peaking units that in total produce approximately 12 MW. These units are primarily used to provide emergency power, but occasionally run during the Summer to provide power during peak load demands.

The location of the new Turkey Point Unit # 5, a "4x1" combined cycle electrical generating unit, is within the existing FPL Turkey Point facility property. The location for Unit # 5 is adjacent to the existing fossil Units # 1 and # 2, and includes the existing parking lot and storage areas immediately northwest of Units # 1 and # 2 as well as mangrove wetlands north of the facility.

a. and b. U.S. Geological Survey (USGS) Map and Proposed Facilities Layout

A USGS map of the Turkey Point plant site, plus a map of the general layout of the proposed generating facilities at the site, are found at the end of this chapter.

c. Map of Site and Adjacent Areas

An overview map of the site and adjacent areas is also found at the end of this chapter.

d. Existing Land Uses of Site and Adjacent Areas

A major portion of the site consists of a self-contained cooling canal system that supplies water to condense steam used by the existing units' turbine generators. The canal system consists of 36 interconnected canals each five miles long, 200 feet wide, and four feet deep. The remaining developed area of the site is where the two fossil steam generating units and 5 diesel generators are located. South of, and adjacent to, the fossil plant are the two nuclear generating units. Further to the south, wetlands have been set aside as part of the Everglades Mitigation Bank in an effort to restore these areas to historical plant communities and hydrological function.

e. General Environmental Features On and In the Site Vicinity

1. Natural Environment

The majority of the site is undeveloped dwarf red mangrove swamp, tidally inundated with waters from Biscayne Bay. Along with the dominant red mangroves, buttonwood is a common canopy component, along with occasional white mangrove. Only a few individual black mangroves were observed within the Site. Biscayne Bay is a shallow, subtropical bay supporting sea grasses, sponges, coral reefs, and a variety of marine life.

2. Listed Species

The construction and operation of Unit # 5 is not expected to adversely affect any rare, endangered, or threatened species. Listed species known to occur in the nearby Biscayne National Park that could potentially utilize the site include the peregrine falcon (Falco peregrinus), wood stork (Mycteria americana), American crocodile (Crocodylus acutus), mangrove rivulus (Rivulus marmoratus), roseate spoonbill (Ajaja ajaja), limpkin (Aramus guarauna), little blue heron (Egretta caerulea), snowy egret (Egretta thula), American oystercatcher (Haematopus palliates), least tern (Sterna antillarum), brown pelican (Pelicanus occidentalis), the white ibis (Eudocimus albus), and bald eagle (Haliaeetus leucocephalus). No bald eagle nests are known to exist in the vicinity of the site. The federally listed, endangered American Crocodile thrives at the Turkey Point site, primarily in and around the southern end of the cooling canals which lie south of the project area. The entire site is considered crocodile habitat due to the mobility of the species and use of the site for foraging, traversing, and basking. FPL manages a program for the conservation and enhancement of the American crocodile. A project-specific crocodile management plan has been developed for construction of Unit # 5.

3. Natural Resources of Regional Significance Status

Significant features in the vicinity of the site include Biscayne National Park, the Miami-Dade County Homestead Bayfront Park, and the Everglades National Park. The portion of Biscayne Bay adjacent to the site is included within the Biscayne National Park, comprised of several miles of shoreline north of the Turkey Point facility extending offshore approximately 12 nautical miles. Biscayne National Park contains 180,000 acres, approximately 95% of which is open water interspersed with over 40 keys. The Biscayne National Park headquarters is located approximately 2 miles north of the Turkey Point plant, adjacent to the Miami-Dade County Homestead Bayfront Park, which contains a marina and day use recreational facilities.

4. Other Significant Features

FPL is not aware of any other significant features of the site.

f. Design Features and Mitigation Options

Turkey Point Unit # 5 will consist of four new CT's, four new HRSG's, and a new steam turbine, resulting in a 4x1 configuration CC unit. This unit is scheduled to be in-service in mid-2007. Natural gas delivered via the existing pipeline is the primary fuel type for this unit (with ultra low sulfur light oil serving as a backup fuel). Natural gas-fired facilities are among the cleanest, most efficient technologies currently available.

Mitigation aspects of Turkey Point Unit # 5 related to unavoidable wetland impacts of construction include; on-site hydrologic improvements to enhance existing wetlands, restoration and preservation of areas overgrown with exotic plant species, creation of an on-site lagoon, transfer of some mangrove dominated lands to South Florida Water Management District and Biscayne National Park, and also the purchase of mitigation credits from the EMB which is in the same drainage basin. The capture and reuse of plant process water and rainwater, plus the use of cooling towers will minimize thermal discharges to the cooling canals.

g. Local Government Future Land Use Designations

Local government future land use plan designates most of the site as IU-3 "Industrial, Unlimited Manufacturing District." There are also areas designated GU – "Interim District." Designations for the surrounding area are primarily GU – "Interim District."

h. Site Selection Criteria and Process

For the past several years, a number of FPL's existing power plant sites have been considered as potentially suitable sites for new or repowered generation. The Turkey Point plant site has been selected as a preferred site due to consideration of various factors including system load, an imbalance in the south Florida region between load and generating capacity, and economics. Environmental issues are an important factor at this site. However, the other deciding factors outweigh them. FPL will minimize environmental impacts and mitigate where impacts are unavoidable.

.

i. Water Resources

Unique to Turkey Point Plant is the self-contained cooling canal system that supplies water to condense steam used by the existing plant's turbine generators. Although the canal system provides sufficient cooling water for the existing units, there is insufficient cooling capacity for the new unit. Sufficient cooling water for the new unit can be obtained from the Floridan Aquifer that lies beneath the plant site and lies deep beneath the surficial Biscayne Aquifer. The Floridan Aquifer contains an ample supple of water which will be acceptable quality and quantity for plant cooling water needs.

j. Geological Features of Site and Adjacent Areas

FPL's Turkey Point site is underlain by approximately 13,000 feet of sedimentary rock strata. The strata that extends to approximately 500 feet forms the Biscayne Aquifer. The basement complex in this area consists of Paleozoic igneous and metamorphic rocks about which little is known due to their great depth.

Overlying the basement complex to the ground surface are sedimentary rocks and deposits that are primarily of marine origin. Below a depth of about 400 feet these rocks are predominantly limestone and dolomite. Above 400 feet the deposits are largely composed of sand, silt, or clay. The Tamiami formation is named for deposits composed principally of white cream-colored calcareous sandstone, sandy limestone, and beds and pockets of quartz sand. In the Turkey Point area, the Key Largo limestone is present.

The Floridan Aquifer, located approximately 1,100 feet below the land surface, is a confined aquifer. The Floridan Aquifer system is composed entirely of carbonate rocks, except for minor evaporates. The water in the carbonate rock aquifer is more highly mineralized.

k. Projected Water Quantities for Various Uses

The additional quantity of water for industrial processing is estimated to be 150 gallons per minute (gpm) for plant process and service water. Water for this type of use would be supplied by an existing county water system. FPL will construct a dedicated water treatment facility specifically for Unit # 5. Cooling water for new Unit # 5 will be processed through cooling towers. FPL proposes to use water from the Floridan Aquifer as the source of make-up water used by the cooling towers. The estimated makeup water quantity to the cooling towers is approximately 9,600 gpm.

l. Water Supply Sources by Type

Unit # 5 will utilize cooling towers for the dissipation of heat from the cooling water. The Floridan Aquifer will supply the makeup water for the cooling towers. A dedicated new water treatment system will be constructed at the site to serve Unit # 5.

m. Water Conservation Strategies Under Consideration

A plan to treat and recycle equipment wash water, boiler blowdown, and equipment area runoff for use as service water would reduce ground water consumption. FPL anticipates this site will be designed and classified as a wastewater zero discharge site following the completion of Unit # 5.

n. Water Discharges and Pollution Control

Heated water discharges for the existing Turkey Point units are dissipated using the existing once-through cooling water system and the cooling canal system. Unit # 5 cooling water will be processed through a cooling tower which will dissipate the heat prior to discharge to the cooling canal system. Non-point source discharges are collected and reused. Treating and recycling equipment wash water, boiler blow-down, and equipment area runoff helps to minimize industrial discharges. Storm water runoff is collected and used to recharge the surficial aquifer via a storm water management system. Design elements have been included to capture suspended sediments. Various facility permits mandate various sampling and testing activities which provide indication of any pollutant discharges.

The facility employs a Best Management Practices (BMP) plan and Spill Prevention, Control and Countermeasure (SPCC) plan to control the inadvertent release of pollutants.

o. Fuel Delivery, Storage, Waste Disposal, and Pollution Control

The site is already serviced by multiple fuel delivery facilities. There is currently a pipeline that supplies natural gas to the facility. The facility also has oil capabilities through on-site storage tanks and accessibility to barge deliveries. Unit # 5 will utilize the existing natural gas pipeline with the addition of compression system(s). A dedicated above-ground storage tank for the ultra-low sulfur distillate backup fuel will also be added. Supply of ultra low sulfur distillate fuel for the new tanks will be made by use of truck deliveries.

p. Air Emissions and Control Systems

The use of natural gas and ultra low sulfur distillate as fuels, plus combustion controls, will minimize air emissions from these units and ensure compliance with applicable emission limiting standards. Using natural gas and ultra low sulfur distillate as fuels minimizes emissions of sulfur dioxide (SO_2), particulate matter and other fuel-bound contaminates. Combustion controls similarly minimize the formation of nitrogen oxides (NO_x), and the combustor design will limit the formation of carbon monoxide and volatile organic compounds. When firing natural gas, NO_x emissions will be controlled using dry-low NOx combustion technology and selective catalytic reduction (SCR). Water injection and SCR will be used to reduce NOx emissions during operations when using the ultra low sulfur distillate as backup fuel. These design alternatives constitute the Best Available Control Technology for air emissions, and minimize such emissions while balancing economic, environmental, and energy impacts. Taken together, the design of Turkey Point Unit # 5 will incorporate features that will make it one of the most efficient and cleanest power plants in the State of Florida.

q. Noise Emissions and Control Systems

A field survey and impact assessment of noise expected to be caused by unit construction at the site indicated that construction noise would be below current noise levels for the residents nearest the site. Noise from the operation of the new unit will also be within allowable levels. Similar natural gas-fired facilities in Broward and Martin counties have been constructed and operated without exceeding allowable noise levels.

r. Status of Applications

The Governor and Cabinet approved certification of the plant on February 7, 2005. Following this certification, the Prevention of Significant Deterioration (PSD) air permit and the Dredge and Fill permits were granted by the respective reviewing agencies. Construction will commence in the Spring 2005 with an anticipated in–service date of mid-2007.

Preferred Site # 4: West County Energy Center, Palm Beach County
