1 BEFORE THE FLORIDA PUBLIC SERVICE COMMISSION

2 PREPARED DIRECT TESTIMONY OF YAPING WANG

3 ON BEHALF OF ST. JOHNS RIVER WATER MANAGEMENT DISTRICT

4 DOCKET NO. 930256-WS

5 JULY 1994

6

7 Q1. Please state your name, business and occupation.

8 A1. My name is Yaping Wang. I am a resource economist with

9 the St. Johns River Water Management District.

10

11 Q2. Please describe your position with your employer and

12 your duties and responsibilities in that position.

13 A2. I have been with the District as a resource economist

14 since April, 1989. My duties include preparing the

15 Economic Impact Statement (EIS) as part of the rule-

16 making process, and a wide range of economic studies

17 concerning land acquisition, wastewater reuse, and

18 water conservation.

19

20 Q3. Please summarize your education and work background.

21 A3. Exhibit 1 is my resume of education and work

22 background.

23

24 Q4. What is the purpose of your testimony?

25 A4. In general, my testimony will explain the effect an

1 inverted rate structure has upon water consumption by a
2 customer of a water utility company. In particular, I
3 will explain the effect that the inverted rate
4 structure, as proposed by Sanlando Utilities, has on
5 water consumption.

6

7 Q5. Please explain the effect upon water consumption that
8 an inverted rate structure is intended to have.

9 A5. The law of demand in economic theory states that as the
10 price of a commodity increases, the demand for that
11 commodity decreases. Price elasticity is the measure
12 of the change in quantity demanded caused by the change
13 in price. The demand for a commodity can be elastic or
14 inelastic. An elastic demand is the one that has a
15 greater percentage change in demand than in price. An
16 inelastic demand is one that has a lower percentage
17 change in demand than in price. Discretionary uses
18 such as irrigation and car washing are relatively
19 elastic demands because they are the most sensitive to
20 changes in water rates.

21

22 By incorporating a per unit charge that increases with
23 an incremental change in water use, an inverted rate
24 structure intends to discourage discretionary water
25 uses. An inverted rate structure generally has no

1 effect on potable water uses, such as drinking, cooking
2 and bathing, since these uses are relatively
3 insensitive to rate changes and are priced at a lower
4 rate. Therefore, reduction in water consumption by an
5 inverted rate structure is mainly experienced in the
6 areas of the larger users and discretionary uses. In
7 the case of Sanlando, the larger users are those who
8 use more than 10,000 gallons per month.

9

10 Q6. Please explain the variables that would affect the
11 conservation that would result from an inverted rate
12 structure.

13 A6. Variables which would have a certain impact on the
14 effectiveness of an inverted rate structure are price
15 elasticity, block rate pricing, block threshold,
16 customer classification, duration and communication.

17

18 Q7. Please explain price elasticity and relate that to the
19 Sanlando Utilities' service area.

20 A7. Individual customers' demand for water can be either
21 elastic or relatively inelastic depending on price
22 level. A study done in southwest Florida has shown
23 that at prices below \$1.00 per 1,000 gallons or above
24 \$6.00 per 1,000 gallons, the demand for water was
25 relatively inelastic regardless of wealth. In

1 addition, price elasticity is different among different
2 wealth groups. The same study suggested that less
3 wealthy customers are more price elastic at \$1.50,
4 whereas wealthy customers are more price elastic at
5 \$3.00.

6
7 In the Sanlando service area, the price is relatively
8 inelastic due to the wealth of the customers as
9 determined by the property values and the current low
10 water price of 35.5 cents per 1,000 gallons.

11 Therefore, it is not expected that water consumption
12 will be significantly reduced under the proposed
13 inverted rate structure because the existing rates are
14 so low when compared with the model.

15

16 Q8. Please explain block rate pricing and relate that to
17 the Sanlando Utilities' service area.

18 A8. In block rate pricing, the price of the second block
19 needs to be sufficiently higher than the price of the
20 first block so that customers have an economic
21 incentive to conserve water. As a guideline, the price
22 of the second block should be at least 25 percent
23 greater than the price of the first block.

24

25 In the Sanlando proposal, the first block is \$0.355 and

1 the second block is \$0.50. Therefore, the second block
2 is over 25 percent, actually 40 percent, greater than
3 the first and there should be an economic incentive to
4 reduce consumption over the 10,000 gallons. Similarly,
5 the price of the third block, \$0.65, is over 25 percent
6 greater than the price of the second block (\$0.50) so
7 there should be a conservation effect. The price of
8 the fourth block, \$0.85, is over 25 percent greater
9 than the third block (\$0.65) so again there should be a
10 conservation effect.

11

12 Q9. Please explain the block threshold and relate that to
13 the Sanlando Utilities' service area.

14 A9. The threshold between the first and second blocks for a
15 given customer classification should take into account
16 the amount of potable water use plus a reasonable
17 amount of discretionary water use and the average water
18 usage for that customer classification. For example,
19 if the average monthly single-family customer water use
20 in a community is 10,000 gallons and the block
21 threshold for the second block is 30,000 gallons,
22 single-family customer water use will not be largely
23 affected by the block rate. As a result, water
24 consumption by the single-family will be minimally
25 reduced because the threshold was too high and the

1 users are not affected by the increased rate. By
2 contrast, if the second block is set at 5,000 gallons
3 for the same community, the customers' discretionary
4 uses will be affected by this block rate but with no
5 ability to further reduce their consumption.
6 Therefore, thresholds that are too low can generate
7 excess revenues because consumption is not reduced
8 where the rate is increased. The major task for the
9 utility is to set meaningful block thresholds that will
10 discourage excessive discretionary water use without
11 generating excess revenues.

12

13 With regard to Sanlando, the proposed block thresholds
14 are acceptable at 0 to 10,000, 10,000 to 20,001, 20,001
15 to 30,000 gallons, and over 30,000. According to
16 Exhibit II of the Petition, 63% of the single-family
17 customers are affected by the block thresholds. This
18 is an acceptable result for block thresholds which
19 should discourage discretionary uses.

20

21 In the Sanlando Utilities' service area, however, over
22 40% of the single-family customers are using more than
23 20,000 gallons a month. This is considered high water
24 consumption pattern when compared with the ten
25 utilities involved in the computer model. Due to low

1 water rates and high water consumption by a large
2 portion of its customers, Sanlando Utilities may
3 generate more excess revenue than it projected under
4 the proposed block thresholds. This situation can be
5 mitigated by adopting a higher block threshold to
6 reduce excess revenue.

7

8 Q10. Please explain customer classification and relate
9 that to Sanlando Utilities' service area.

10 A10. There should be different block thresholds for each
11 customer classification, such as single-family
12 residential, commercial and industrial, and irrigation,
13 because different classifications have different uses
14 of water. For example, if the first block is designed
15 based on a monthly average single-family residential
16 water usage of 10,000 gallons, it would be unlikely
17 that the rate would have any effect on water
18 consumption of a commercial customer such as a 300 unit
19 hotel.

20

21 With regard to Sanlando, there are four blocks.
22 Exhibit 1 to the plan shows the customer usage for
23 residential, general service, multi-family, and bulk
24 sales. The four proposed blocks coincide with the
25 different customer classifications with the over 30,000

1 block appearing to have the most significant effect.

2

3 The largest block, over 30,000, would include the
4 majority of the general service, multi-family and bulk
5 sales users according to Exhibit 1. With the inverted
6 rate structure, the rate for the over 30,000 gallons
7 users increases to \$0.85 per 1,000 gallons. Therefore,
8 there would be an incentive to conserve water for those
9 users.

10

11 The residential consumption is distributed over the
12 four block thresholds. For the users over 10,000,
13 there is a conservation effect and the effect increases
14 with each block.

15

16 Q11. Please explain the duration variable and relate that
17 to the Sanlando Utilities' service area.

18 A11. Like other water conservation rate structures, an
19 inverted rate structure is effective in the short term,
20 but it tends to diminish over time because consumers
21 become accustomed to the new rate structure and because
22 the real price falls over time. Therefore, the
23 inverted rate needs regular monitoring and updating to
24 be effective over the long term.

25

1 The Sanlando proposal is for four years to fund the
2 reuse project. After four years, it would be wise to
3 review the rates and usage for possible continuation.
4 Q12. Please explain the variable of communication and
5 relate that to the Sanlando Utilities' service area.
6 A12. Water conservation by the inverted rate structure
7 will be maximized if the utility has communicated this
8 rate to its customers frequently. Customers need to be
9 informed about the price of water and how much they
10 have used so that they can respond to the pricing
11 signal and use water efficiently. Better communication
12 to customers can be achieved through clear
13 documentation of water rates, historic and current
14 water use on water bill and the water use should be
15 presented in gallons per day. Additionally, billing
16 frequency should be monthly or, at least, bimonthly as
17 opposed to quarterly.
18
19 Q13. Please explain the overall effect of an inverted rate
20 structure upon water consumption and consequent reduced
21 water withdrawals from the aquifer.
22 A13. The inverted rate structure is the most well known of
23 the conservation rate structures, and it has been used
24 by many utilities in Florida and throughout the U.S.
25 An inverted rate structure may affect customers, the

1 utility, and the water resources of the state. The
2 overall effect of an inverted rate structure, if
3 properly designed, would primarily reduce customers'
4 discretionary uses such as irrigation and car washing.
5 At a high enough price, demands for potable uses may
6 also be reduced. However, demand for potable uses are
7 relatively inelastic to small or moderate changes in
8 rates because these uses are essential to an accepted
9 lifestyle.

10

11 As the demand for water is reduced, the utility may be
12 able to delay plant or wellfield expansion. The delay
13 in plant or wellfield expansion can be translated to
14 cost savings to the utility and its customers as well.

15

16 If an inverted rate structure can reduce water
17 consumption, the withdrawals from the aquifer or other
18 sources can also be reduced. This is especially
19 beneficial in an area which has experienced, or may
20 experience in the future, water shortage problems or in
21 an area of water quality concerns.

22

23 Q14. How do you determine the effect that an inverted rate
24 structure has upon water consumption?

25 A14. There is a computer model designed by and a

1 methodology as presented in Definition of Water
2 Conservation Promoting Rates, Feb.1993, Water Price
3 Elasticity Study, August 1993, and Water Conservation
4 Promoting Rate Structure Computer Model, September
5 1993. These reports were prepared by Brown and
6 Caldwell in cooperation with the Southwest Florida
7 Water Management District.

8

9 Q15. How does the model work?

10 A15. Given the water usage at the existing rates and the
11 proposed blocks and rates for each block, the model
12 will give an average percent of overall consumption
13 reduction.

14

15 Q16. Have you had the opportunity to review the Proposed
16 Water Reuse Program First Amendment Dated 1/31/93
17 Sanlando Utilities Corporation which was attached to
18 the petition filed by Sanlando Utilities Corporation in
19 this case?

20 A16. Yes.

21

22 Q17. If put into effect, what will be the conservation
23 effect of the rate structure that Sanlando Utilities
24 Corporation has included in its petition?

25 A17. Using the computer model, it is estimated that total

1 water consumption of Sanlando Utilities would be
2 reduced by 4.6 percent if the proposed inverted rate
3 structure is adopted. This is an average reduction of
4 all four blocks.

5

6 Q18. How does each block contribute to the 4.6 percent?

7 A18. Since the 4.6 percent reduction reflects the combined
8 effect of the four blocks and rates, the contribution
9 for each block is determined by modeling each rate
10 across the board for all consumption. The model is run
11 three separate times to determine the contribution for
12 each block rate. It is estimated that a rate of \$0.50
13 per 1,000 gallons would reduce total water use by 3.0
14 percent, \$0.65 per 1,000 gallons by 5.4 percent, and
15 \$0.85 per 1,000 gallons by 8.5 percent.

16

17 Q19. Is the 4.6 higher or lower than that estimated by
18 Sanlando Utilities?

19 A19. Sanlando estimated a total water consumption of 9.7
20 percent. The lower reduction rate estimated by the
21 District is due to the use of the model which is
22 affected by the relatively high percentage of "wealthy"
23 customers within its service area and relatively low
24 water price even after the inverted rate structure is
25 implemented.

1 The customer base is categorized as wealthy based on
2 the variables defined by the model. One variable in
3 determining wealth is the home value in the area as
4 determined from census data. In the customer service
5 area of Sanlando, over 80% of the homes are valued over
6 81,000. Therefore, the increased rate will not have as
7 large an effect as it would if the increased rate were
8 imposed on a service area with homes of a lesser value.

9

10 Q20. What would the inverted rates for each block be if
11 the overall reduction is 10% as proposed by Sanlando
12 Utilities? Please explain how you determined this.

13 A20. The overall reduction of 10% can be determined using
14 the same computer model. The model consists of three
15 modules, including the Bill Frequency Module, the Price
16 Impact Module, and the Revenue and Water Use Impact
17 Module, which together determine the impact on water
18 use and revenues of the proposed rates. If the results
19 are not acceptable at the 4.6 percent reduction level
20 the user can explore other options by changing the
21 proposed water rates in the Price Impact Module until a
22 rate structure is found that both derives necessary
23 revenues and achieve the desired level of water use
24 reduction. However, this would be difficult in certain
25 circumstances where water rates are so low and/or

1 customers' income is so high that price elasticity of
2 water tends to become very low.

3

4 In the Sanlando case, a 10 percent reduction can be
5 achieved by increasing the third and fourth block rates
6 to \$1.10 and \$2.20 per 1,000 gallons, respectively, for
7 residential customers, while charging a flat rate of
8 \$0.75 per 1,000 gallons at the third and fourth blocks
9 for multi-family, and commercial and industrial users.
10 Exhibit 2 shows this alternative. The lower charge for
11 multi-family, and commercial and industrial users takes
12 into account the effect of the lower price elasticity
13 of these customers. If all customer classes were
14 charged at the same block rate, more excess revenue
15 will be generated at the same water reduction level.
16 Exhibit 3 shows this alternative. Still, both
17 alternative rates generate more excess revenue than
18 that by the proposed rates.

19

20 Q21. Please summarize your testimony.

21 A21. The inverted rate structure is the most well known of
22 the conservation prompting rate structures, and it has
23 been used by many utilities in Florida and throughout
24 the U.S. By incorporating a per unit charge that
25 increases with incremental change in water use, an

1 inverted rate structure intends to discourage
2 discretionary uses such as irrigation and car washing.
3 At a high enough price, demands for potable uses may
4 also be reduced.

5
6 Adopting an inverted rate structure does not guarantee
7 reduction in water consumption. Among many variables
8 that would affect the effectiveness of an inverted rate
9 structure, price elasticity is the key variable to
10 determine the reduction level of different customer
11 groups.

12
13 If Sanlando Utilities' proposed inverted rate structure
14 is adopted, it is estimated that total water
15 consumption of Sanlando Utilities would be reduced by
16 4.6 percent. The low reduction rate is due primarily
17 to relatively high percentage of wealthy customers
18 within its service area and relatively low water price
19 of Sanlando Utilities.

20

21 Q22. Does this conclude your testimony?

22 A22. Yes.

23

24

25

YAPING WANG, AICP
Resource Economist
St. Johns River Water Management District

Areas of Specialization

Economic impact statement, wastewater reuse, leak detection, rate structure, alternative water use, water conservation, comprehensive planning, cost/benefit analysis, socio-economic and population studies.

Education

1989 M.S., Urban Planning, University of Wisconsin-Milwaukee
1982 B.A., Architecture, Tong Ji University, China

Professional Experience

1989-Present Resource Economist, St. Johns River Water Management District.
Prepared all the economic impact analysis (EIS) for the District as part of rule-making process. Conducted a wide range of economic studies concerning land acquisition, wastewater reuse, and water conservation.

1987-1989 Consultant, SRI International
Assessed economic development opportunities for Saginaw, Michigan, State of Nebraska, Iowa, and North Dakota. Conducted statistical analysis on factors attributed to regional productivity difference.

1986-1988 Research Assistant, University of Wisconsin-Milwaukee
Provided statistical analysis for various research project. Conducted surveys on education programs among state planners. Taught graduate students computer applications.

1984-1985 Research Analyst, Shanghai Investment and Trust Corp., China
Identified and assessed business opportunities for foreign companies in real estate development projects. Conducted feasibility studies for hotel and condominium development.

1982-1984 Architect, Shanghai Architectural Design Institute, China
Selected and planned sites for residential, institutional and commercial development. Designed apartment buildings and commercial complex.

10/0 reduction

Table 22 OUTPUT Projected Water Use Change by Customer Class, kgal

Customer Class	Water Use Change, percent(a)	Projected Annual Water Use, kgal (b)	Water Use Change, kgal (c)	Net Projected Annual Water Use, kgal (d)
Single Family	-11.59%	2,449,924	(283,968)	2,165,956
Multiple Family	0.00%	171,245	0	171,245
Commercial	-5.86%	312,462	(18,309)	294,153
Industrial	-7.45%	159,952	(11,924)	148,028
Total	-10.16%	3,093,583	(314,200)	2,779,383

(a)From Table 16 in Price Impact Module.
 (b)From Table 20.
 (c)Water use change percent times projected water use.
 (d)Projected water use plus water use change.

SJRWMD EXHIBIT 3b

Table 23 OUTPUT Revenue Impact by Rate Component and Customer Class

Description	Projected Revenue
Revenue Generated With Proposed Rates (a)	
Service Charge	
Meter Independent	0
Meter Dependent	795,992
Subtotal, Service Charge	795,992
Quantity Charge	
Single Family	1,985,949
Multiple Family	264,546
Commercial	481,058
Industrial	294,796
Subtotal, Quantity Charge	3,026,350
Total Revenue Generated	3,822,342
Revenue Requirements (b)	
Service Charge	
Meter Independent	797,416
Meter Dependent	0
Subtotal, Service Charge	797,416
Quantity Charge	
Existing Revenue Requirement	1,098,222
Change in Revenue Requirement (variable costs)	(11,154)
Subtotal, Quantity Charge	1,087,068
Total Revenue Requirement	1,884,484
Revenue Surplus (Shortfall)	1,937,858

(a) Calculated using Net Projected Water Use from Table 22, proposed weighted water rates from Table 10, and service charges from Table 5 in Price Impact Module. Accounts and equivalent accounts from Table 17 and 19, respectively.

(b) Projected revenue requirements from existing rates from Table 21 adjusted for change in variable costs. The variable cost percent of quantity charge revenue requirements can be adjusted in cell F9.
