

March 28, 2002

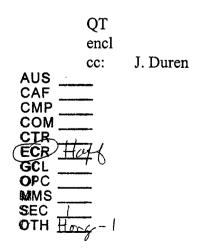

Ms. Blanca S. Bayó, Director Division of Public Records and Reporting Florida Public Service Commission 2540 Shumard Oak Blvd. Tallahassee, FL 32399

Dear Ms. Bayó:

In accordance with Section 186.801, Florida Statutes, Seminole Electric hereby submits twenty five (25) copies of our 2002 Ten Year Site Plan (TYSP).

Any questions or comments regarding Seminole's submittal will be greatly appreciated. Either Jim Duren, Vice President, Energy Production, or I will be happy to discuss the TYSP in more detail.

Kichard J. Midulla Executive Vice President and General Manager

Seminole's Member Distribution Cooperatives

FLORIDA

1. DESCRIPTION OF EXISTING FACILITIES

1.1 Overview

Seminole Electric Cooperative, Inc. (Seminole) is a corporation organized and existing under the laws of the State of Florida for the purpose of providing reliable electric power at the lowest feasible cost to its ten distribution members systems. This is accomplished by generating, transmitting, purchasing, selling, exchanging, etc. electric power and energy, and constructing, owning, leasing, etc. such facilities as required for this purpose.

The Seminole member cooperatives are as follows:

- Central Florida Electric Cooperative, Inc. Chiefland, Florida
- Clay Electric Cooperative, Inc. Keystone Heights, Florida
- Glades Electric Cooperative, Inc. Moore Haven, Florida
- ► Lee County Electric Cooperative, Inc. North Fort Myers, Florida
- Peace River Electric Cooperative, Inc.
 Wauchula, Florida
- Sumter Electric Cooperative, Inc. Sumterville, Florida
- Suwannee Valley Electric Cooperative, Inc. Live Oak, Florida
- Talquin Electric Cooperative, Inc. Quincy, Florida
- Tri-County Electric Cooperative, Inc. Madison, Florida
- Withlacoochee River Electric Cooperative, Inc. Dade City, Florida

Each of these members is at present engaged primarily in the distribution of retail electric power; Seminole supplies full requirements power to the members. The map at the beginning of this section indicates the counties in which each member of Seminole provides service.

1.2 Owned Resources

ł

1.2.1 Generation. Seminole serves its aggregate member system load with a combination of owned and purchased power resources. Seminole Generating Station ("SGS") Units 1 & 2, 600 MW class coal-fired units, began commercial operation on February 1, 1984 and January 1, 1985, respectively. Payne Creek Generating Station ("PCGS") Unit #1, a 500 MW class combined cycle unit began commercial operation on January 1, 2002. Seminole owns a 14.5 MW share of Florida Power Corporation's ("FPC') Crystal River 3 nuclear generating unit which is operated by FPC. A more detailed description of Seminole's owned facilities is provided on Schedule 1.

1.2.2 Transmission. Seminole owns a 52 mile 230 kV double circuit transmission line from the Seminole Plant to the Silver Springs North switching station, an eight mile double circuit line from the Seminole Plant to FPL's Rice Substation and a nine mile single circuit transmission line from the Hardee Power Station ("HPS") to FPC's Vandolah Substation. Seminole also owns a 78 mile of 230 kV single circuit transmission line from HPS to Lee County Electric Cooperative's Lee Substation (a tie with FPL), and a 63 mile of single circuit transmission line from the SGS to an interconnection with Jacksonville Electric Authority at the Clay-Duval county line. Seminole jointly owns with FPC two 230 kV tie lines from Silver Springs North to FPC's Silver Springs substation.

Seminole owns fourteen (14) 69 kV transmission lines totalling143.2 miles in length: Clewiston to Cowbone Hammock, Otter Creek to Bronson, Otter Creek to Cedar Key, Cross City

to Steinhatchee, Ortona Tap to Ortona, Spring Lakes to Lorida, Andersen to Lake Panasoffkee, Belleview to Marion Oaks, Central Florida to Continental, Howey to Astatula, Altoona to Linadale, Scanlon Tap to Scanlon, Ft. Basinger to Basinger and Moore Haven to Lakeport. These facilities are shown on page 6.

1.3 Purchased Power

Seminole's generation portfolio includes the following purchase power agreements¹:

- Jacksonville Electric Authority ("JEA") 63 MW of firm peaking capacity through August, 2004;
- Orlando Utilities Commission ("OUC") 75 MW of firm intermediate and peaking capacity through May 2004;
- ► Florida Power Corporation ("FPC") -
 - 150 MW of firm system intermediate capacity through 2013;
 - 300 MW of firm system peaking capacity through 2002;
 - Partial Requirements Load following requirements service through December 2013.
- Lee County Resource Recovery 35 MW of firm base load capacity through November 2004;
- Reliant 364 MW of firm peaking capacity through December 2006;
- Constellation 364 MW of firm peaking capacity December 2002, increasing to 546 MW beginning May 2003, thru December 2009;

¹ All ratings are winter unless otherwise noted.

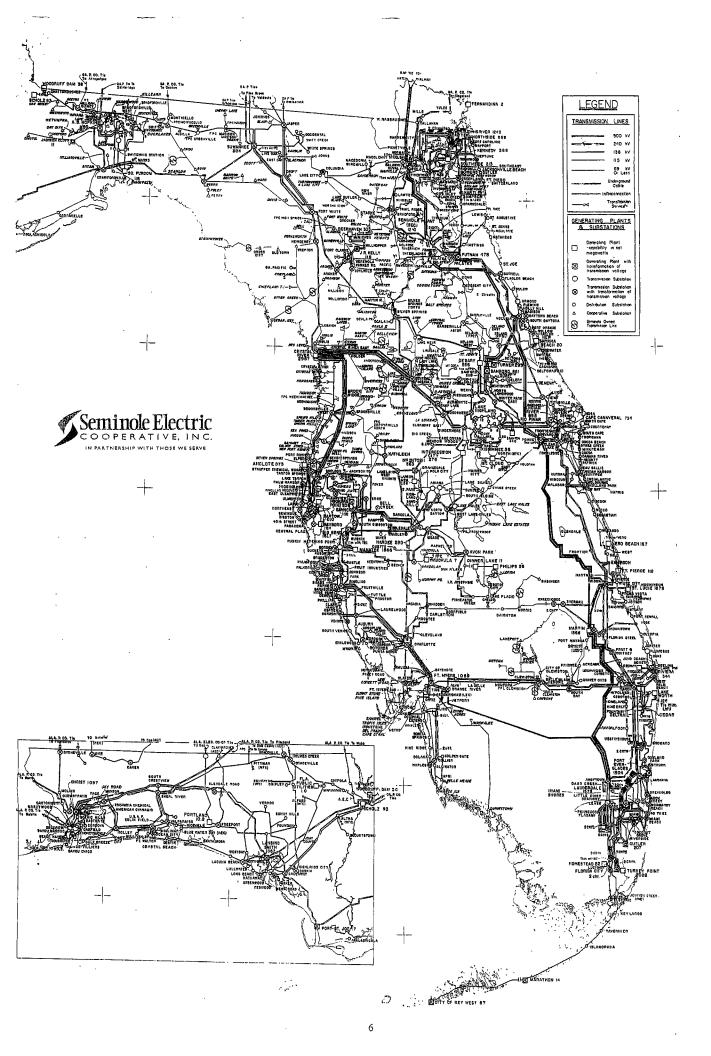

- Calpine 360 MW of firm intermediate capacity for the period June 2004 thru
 May 2009, with openers for possible extension thereafter.
- ► TECO Power Services ("TPS") -
 - 362 MW of first call reserve capacity from the Hardee Power Station (HPS) to cover a forced or scheduled outage or reduced capability of SGS and CR3.
 - 145 MWs of firm base load capacity from Tampa Electric Company's ("TEC") Big Bend No. 4 for any purpose, subject to an annual energy cap, through December 2002.
- Tampa Electric Company ("TEC") Full requirements service with no termination date.
- Gainesville Regional Utilities ("GRU") Full requirements service with no termination date.

1.4 Demand Side Management (DSM)

Seminole and its member systems utilize a variety of DSM and energy conservation programs. These programs include direct load control, distribution system voltage reduction, contractually interruptible load, customer-based generation, energy audits, insulation up-grades, and lighting conversion. Seminole's coordinated DSM program reduces Seminole's peak demand. The load forecast takes into account reductions due to DSM. Such reductions are estimated using analysis methods which incorporate trends in consumer growth, housing size and appliance saturations. While the effect of conservation is also reflected in the load forecast, it's

2. FORECAST OF ELECTRIC POWER DEMAND AND ENERGY CONSUMPTION

2.1 Latest Trends

2.1.1 Service Area Economy. Seminole's member systems provide electricity to an area approximately 400 miles long, bounded by the Apalachicola River and the Georgia border down to the southwestern and south-central regions of Florida. The variety of geographic and weather conditions yields a diverse mix of economic activity as well as demographic characteristics.

2.1.2 Population and Consumers. Population growth in Florida (including Seminole members' service areas) is significantly influenced by migration from northern states. Therefore, national economic factors influencing migration have a large impact on population growth in areas served by Seminole's members.

Residential consumers increased at an annual rate of 12,000 in the early 1990s. Since 1995 annual growth in residential consumers has averaged more than 15,200 per year. In 2000 over 16,000 residential consumers were added, approaching the all time highs of the 1980's. Robust growth in commercial customer load in the 1980s was followed by slower growth in 1990 and 1991. Since 1991, the commercial consumer growth has increased, averaging 3.9 percent annually. During the past five years, commercial customer growth rates have surpassed residential consumer growth rates.

Historically, Seminole's residential consumers have increased at a faster rate than Florida. For the period of 1990-2000, Seminole's residential customer growth rate was 2.87 percent compared to 2.3 percent for Florida.

2.1.3 Income. A number of counties in Seminole's five largest member service areas experienced higher growth in per capita income than the Florida average. Statistics indicate that

almost 40 percent of the income in Florida comes from non-wage sources such as dividends, interest, rent, and transfer payments. This is approximately 10 percentage points higher than national averages. This statistic reflects the high concentration of retirees, especially in the more affluent parts of the service area. These types of income are relatively stable and consequently help absorb the impacts of economic changes on the Florida economy and Members service area.

2.2 Forecast Results

2.2.1 Overview. Consumers, energy, and peak demand growth rates for the Seminole system have been higher than those for Florida as a whole during the past decade. This pattern is expected to continue in the future even though both Florida and the Seminole system are expected to grow at slower percentage rates.

2.2.2 Population. Historical and forecasted population for Seminole's members' service area are shown on Schedule 2.1. In 2001, total population in the service area was estimated at approximately 1.4 million, which is projected to grow to 1.7 million by 2011.

2.2.3 Consumers. Seminole's members serve a significant portion of the less urbanized areas of the state which are located adjacent to metropolitan areas. It is therefore reasonable to expect continued higher consumer growth rates for Seminole's members than for Florida as a whole. The forecasts of residential consumers are shown in Schedule 2.1 and the forecast of commercial consumers is shown in Schedule 2.2.

2.2.4 Usage per Consumer. Between 1990 and 2000, residential usage per consumer in Seminole members' service area increased at a compound annual rate of 2.1 percent as compared to the State average of 1.2 percent. The continued growth of average usage is consistent with the Residential Appliance Survey results which show steady increases in appliance saturations and larger homes during the last decade.

The continued increases in residential usage per consumer resulted in the Seminole system statistics reaching approximately the same usage level as the state average. The annual average residential usage of Seminole members was 13,166 KWh compared to the State's average of 13,099 KWh that year. In 2000, the Seminole system average usage dropped slightly lower than the Florida average, 13,717 KWh compared to 13,741 KWh.

Per consumer usage on the Seminole system is expected to grow at 1.4 percent annually through 2010. The continued trend toward larger homes, continued increases in appliance saturations, and stable or lower electricity prices will all contribute to higher energy consumption levels in the future.

Commercial/industrial usage per consumer is much lower on the Seminole system than in Florida as a whole, 54,679 KWh versus 80,052 KWh in 2000. Seminole members' commercial usage also includes industrial consumers, whereas the Florida average does not. Commercial/industrial usage per consumer is projected to grow at an average annual growth rate of 1.3 percent through 2010.

2.2.5 Energy Sales and Purchases. Residential energy sales are projected to grow at 3.8 percent annually between 2002 and 2011. This forecast incorporates anticipated increases in energy savings due to additional future conservation. Commercial energy sales are projected to grow at an annual average of 3.8 percent, over the same period. The forecasts of residential, commercial, and other classes sales are shown on Schedules 2.1 and 2.2.

2.2.6 Peak Demand. Seminole's winter peak demand is projected to increase to 4,982MW and its summer peak demand is projected to increase to 3,945 MW by 2011.

Seminole as a whole and most of the member systems are expected to continue to be winter peaking. For the Seminole system, winter peaks are expected to be approximately 26

percent higher than summer peaks. This continued winter-peaking nature of the Seminole system is due primarily to continued prominance of electric space-heating saturation in the foreseeable future.

The peak demand forecasts reflect no additional load management. At this time most of Seminole's members do not plan to expand their load management programs and a few are evaluating the economic feasibility of maintaining their current programs into the future. The annual load factor for the Seminole system is expected to remain relatively level at 45 percent during the forecast period.

Schedules 2.1, 2.2, and 2.3 summarize energy usage and consumer members by customer class. Schedules 3.1.1, 3.1.2, and 3.1.3 provide summer peak demand forecasts for base, high population and low population scenarios. Schedules 3.2.1, 3.2.2, and 3.2.3 provide similar data for winter peak demand.

2.2.7 Forecast Scenario. Forecast sensitivities are represented by high and low population scenarios representing population growth differences.

2.3 Forecast Assumptions

2.3.1 Economic and Demographic Data. Seminole's economic and demographic data base has three principal sources: (1) population and income data from the Florida Economic Data Base furnished by the Bureau of Economic and Business Research (BEBR) at the University of Florida, (2) electricity price data from Seminole's member cooperatives "Financial and Statistical Reports" (RUS Form 7), and (3) appliance and housing data from the Residential Appliance Surveys conducted by Seminole and its member systems since 1980.

Population is the main explanatory variable in the residential and commercial/industrial consumer models. Historical data on population and personal income by county is obtained for the 45 counties served by Seminole member systems. Combining the county forecasts yields a population forecast for each member. Three sets of population forecasts for each county are provided by BEBR: medium, low, and high scenarios. Historical population growth trends are analyzed to determine the most appropriate combination of scenarios for each member system. High and low population scenarios are developed for each member.

The commercial/industrial energy usage model uses Real Per Capita Income (RPCI) as an explanatory variable. The Consumer Price Index for All Urban Consumers (CPI-U) published by the U.S. Bureau of Labor Statistics is used to convert historical nominal income to real values. Forecasts of RPCI by county are taken from "The Florida Long-Term Economic Forecast 2000."

The real price of electricity is used in the residential and commercial/industrial energy models. The real price is calculated by dividing KWH sales for each consumer class by the corresponding revenue, and then by deflating the result by the CPI-U. For the forecast, the real price of electricity is assumed to decline in the future at an average annual rate of 0.987%. This

rate is based on system wide historical declines in retail rates.

Appliance saturations and housing data are obtained from Seminole's Residential Appliance Survey. The three housing types distinguished in the survey are single-family homes, mobile homes, and multi-family homes. Homes are also segregated into three age groups: less than 5 years old, between 5 and 15 years old, and more than 15 years old. For each category of home type and age combination, the appliance saturations include room air-conditioners, central air-conditioners, electric space-heating appliances, and electric water heaters.

The information from the surveys is combined with the residential consumer forecast to produce weighted appliance stock variables for space-conditioning appliances which are used in the residential energy usage model and the peak demand load factor model.

2.3.2 Weather Data. Seminole obtains hourly weather data from the National Oceanic and Atmospheric Administration (NOAA) for six weather stations located in or around Seminole's members' service area. In order to better reflect weather conditions in each member's service territory, different weather stations are assigned to individual member systems based on geographic proximity.

Monthly heating and cooling degree hours (HDH, CDH) are used in the energy usage models, while the peak demand models use HDH and CDH on Seminole's peak days. Seminole uses individual temperature cut-off points for air conditioning and space heating demand. The extent of the members' service territory also requires different winter cut-off values for the northern and southern regions. These weather variables have been proven effective in explaining weather-neutral temperature ranges for space-conditioning appliances and lagging weather effects within a period of time.

2.3.3 Sales and Hourly Load Data. Monthly operating statistics have been furnished by the member systems to Seminole, beginning with 1970. Included in this data are statistics by class on number of consumers, KWH sales, revenue, and others. This data is the basis for consumer and energy usage models.

Hourly loads for each member and the Seminole system, as well as the members' monthly total energy purchases are collected from over 160 delivery points, covering the period from January 1979 to the present. This data is a basis for modeling peak demand and hourly load profile forecasts, and for load management implementation.

2.4 Forecast Methodology

Seminole's Integrated Forecasting System consists of the following sub-models:

- (1) Residential Consumer Model
- (2) Appliance Model
- (3) Commercial/Industrial Consumer Model
- (4) Other Class Consumers Model
- (5) Residential Energy Usage Model
- (6) Commercial/Industrial Energy Usage Model
- (7) Other Class Energy Usage Model
- (8) Peak Demand Load Factor Model
- (9) Hourly Load Profiles and Load Management

Each model consists of ten sub-models, since each member system is modeled and

forecast separately. Figure 1 shows the Integrated Forecasting System.

2.4.1 Consumer Models. For each member, the historical relationship between annual consumers and the member's service area population is statistically determined using an ordinary

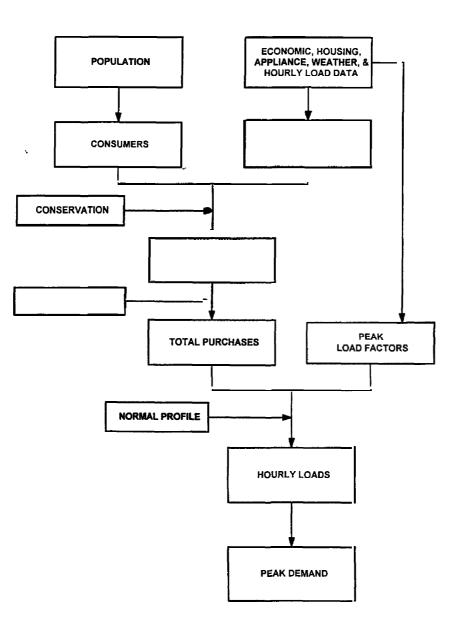

least squares technique, with a first-order auto-regressive correction when necessary. The estimated equations are applied to the population forecasts to generate annual forecasts of residential and commercial consumers. Forecasts are benchmarked using 2000 actual data. Seasonally adjusted monthly forecasts are developed from the annual data. Whenever members expect new large commercial consumers in the near future, the information is implemented in the forecasts.

Other consumer classes generally include irrigation, street and highway lighting, public buildings, and sales for resale, which represent less than 2 percent of Seminole's members' total energy sales. Some member systems include some of these classes in the commercial/industrial sector. For the others, annual consumer forecasts are projected using regression analysis against population, or a trending technique.

Figure 1

Integrated Forecasting System

_ī

٦

.

2.4.2 Appliance Model. The Appliance model combines the results of the Residential Consumer Model with data from the Residential Appliance Survey to yield forecasts of spaceheating and air-conditioning stock variables which are used in the Residential Energy Usage Model and the Peak Demand Load Factor Model. Annual forecasts of the shares of each home type are produced: single-family homes, mobile homes, and multi-family homes. Next, annual forecasts of space-conditioning saturations are created. Finally, the air-conditioning saturations and the space-heating saturations are combined with housing type share information, resulting in weather-sensitive stock variables for heating and cooling.

2.4.3 Energy Usage Models. The Residential Energy Usage Model is a combination of econometric and end-use methods. For each member system, monthly residential usage is modeled using ordinary least squares as a function of explanatory variables including heating and cooling degree variables weighted with space-conditioning appliances, real price of electricity and real per capita income. Monthly forecasts are benchmarked against weathernormalized energy in the last year of the analysis period. Then the monthly usage per consumer forecasts are multiplied by the monthly residential consumer forecasts to produce monthly residential energy sales forecasts.

For each member system, monthly commercial/industrial usage per consumer is modeled as a function of several explanatory variables, which include monthly heating and cooling degree variables, real price of electricity, real per capita income, and dummy variables for some member systems to explain abrupt or external changes. Some members' models use monthly precipitation variables because irrigation consumers are included in this classification. Ordinary least squares methodology with a first order auto-regressive correction is used to produce the monthly energy usage per consumer forecasts which are adjusted for the last year of the historical period. Then

the forecasts are combined with the consumer forecasts to produce monthly commercial/industrial KWH sales forecasts. Whenever members expect new large commercial consumers in the near future, the information is implemented in the forecasts.

Historical patterns of energy usage for other classes have been quite stable for most members and usage is held constant for the forecast period. Trending methodology is used for the members with growth in this sector.

2.4.4 Total Sales and Purchases. The sales forecasts for Residential, Commercial/Industrial and Other classes are summed up for a total sales forecast by month for each member system. The sales forecast is converted to member purchases at delivery point levels using historical averages of the ratio of calendar month purchases to billing cycle sales for each member. Therefore, these adjustment factors represent both energy losses and the difference between the billing cycle sales and calendar month purchases; the latter, as a function primarily of weather and billing days, often changes erratically.

2.4.5 Peak Demand Load Factor Model. The Peak Demand Load Factor Model relates monthly peak load factors to a set of explanatory variables including heating and cooling degree variables, precipitation, air-conditioning and space-heating saturations, and heating and cooling degree hours at the time of the member's peak demand. Two seasonal equations for each member system are developed: one for the winter months of November through March and the other for the summer months April through October. The forecast monthly load factors are combined with the purchases forecasts to produce forecasts of monthly peaks by member.

2.4.6 Hourly Load Profiles. Hourly demand forecasts are created through a calibration procedure which transforms the normal profiles in such a way that maximum peak, monthly minimum, and monthly energy match the monthly forecasts generated from the above-

explained forecasting process. This calibration procedure produces hourly profile forecasts by month and by member, an aggregation of which then constitutes hourly profiles for Seminole system.

2.4.7 Scenarios. Two sets of scenarios are developed in addition to the base case: one for economic scenarios and the other for weather. In lieu of economic scenarios, population which is the main driving force behind Seminole's load growth, is tested, and high and low population growth scenarios are developed for each member system based on BEBR's alternative scenarios.

Severe and mild weather scenarios are developed for the energy usage and load factor models using the severe and mild data which is obtained by averaging the three highest or lowest weather in each month during the past 20 years.

3. FORECAST OF FACILITIES REQUIREMENTS

Seminole's load is located within three control areas, Florida Power Corporation ("FPC"), Florida Power & Light Company ("FPL"), and Seminole's Direct Service Area ("SDS"). Seminole is obligated to serve all load in the FPL and SDS areas, and load up to a specified capacity commitment level in the FPC area. Seminole must also supply appropriate reserves for the load it is responsible to serve. Seminole meets its total committed load obligation using a combination of owned generation and purchased capacity resources. Demand in excess of the specified FPC capacity commitment level is served through partial requirement (PR) purchases from FPC. As load grows, Seminole's PR supplier is responsible for providing capacity to meet load growth and associated reserves above the capacity commitment levels.

The Florida Public Service Commission issued its order approving the need for PCGS June 21, 1994. On August 15, 1995 Seminole received certification for PCGS pursuant to the Florida Electrical Power Plant Siting Act. Construction began on the PCGS in February 2000 and the unit began commercial operation January 1, 2002.

As the result of an all sources RFP process in 1999, Seminole entered into a power purchase agreement with Reliant Energy Osceola, LLC, for 306 MW of firm peaking capacity for the period December 2001 through 2006. Seminole has also entered into a power purchase agreement with Constellation Oleander Power Project, Limited Partnership, for 364 MW of firm peaking capacity for the period December 2002 through May 2003, increasing to 546 MW for the period June 2003 through December 2009.

Seminole issued an all sources RFP in July 2000 which resulted in a contract for 350 MW of combined cycle capacity from the Calpine Energy Services, L.P., Osprey Energy Center for a twenty (20) year period beginning June 2004 with prices reopeners every 5 years. Seminole

also has the option to call on the remainder of the unit capacity (approximately 177 MW) subject to prior sales.

Seminole has a FERC-filed qualifying facility program which complies with the requirements of the Public Utility Regulatory Policies Act (PURPA). In 1999, Seminole entered into a power purchase agreement with a qualifying facility, Lee County Resource Recovery, for approximately 35 MW of capacity. Seminole does not currently have any other qualifying facilities or small power producers on its system, but continues to solicit proposals from them when competitively bidding for power supplies. Also, Seminole evaluates all unsolicited QF proposals for applicability to the cooperative's needs.

Schedules 7.1, 7.2 and 8 include the addition of a total of 2366 MW of capacity in 2006 through 2012 at Payne Creek and yet unspecified sites. Such capacity is needed to replace expiring purchased power contracts and/or to maintain Seminole's reliability criteria. These needs are specified as Combustion Turbine units for planning purposes only. Future studies will optimize the amount, type, and timing of such capacity. The exact type of capacity (CT, purchased power, phased combined cycle, etc.) and source or location will be determined later. Because these units are for planning purposes only, no Schedule 9 is included for these units. The addition of this capacity, at sites to be determined by Seminole, is Seminole's "Backstop" expansion plan.

4. OTHER PLANNING ASSUMPTIONS AND INFORMATION

4.1 Transmission Constraints

Seminole analyzes the transmission system impact on expansion plans using the FRCC load flow databank transmission model. In Seminole's current Ten Year Plan there are no firm new sited units (i.e., assuming Seminole purchases future capacity thru PPAs). The transmission system analysis indicated that no new transmission is required. Seminole is working with the PPA providers and participating in a joint Central Florida Study to ensure adequate transmission capacity is available for the specified purchases.

4.2 Plan Economics

Power supply alternatives are compared against a base case scenario which is developed using the most recent load forecast, fuel forecast, operational cost assumptions, PR rate projections and financial assumptions. Various power supply options are evaluated to determine the overall effect on the Present Worth of Revenue Requirements (PWRR). The option with the lowest PWRR is normally selected, all other things being equal. Sensitivity analyses are done using both the high population growth scenario and the low population growth scenario from the current load forecast as well as extreme weather sensitivities, along with fuel forecast sensitivities.

4.3 Fuel Price Forecast

4.3.1 Coal. The base forecast anticipates that price increases for coal will be less than IPD because of continued improvements in productivity enabling industry wide production to outpace growth in demand. Thus, the moderate over-supply and competitive pricing which has typified the industry in recent years is expected to continue, resulting in the forecast for only moderate price increases.

The high case projects that prices will grow in the ball park of IPD because of a cessation of

historic improvements in productivity leading to a tighter supply-demand relationship. The low case projects a decrease in prices as a result of technological advances which reduce the impact of labor cost and increase production causing an over-supply of coal with such vigorous price competition that prices actually decrease.

4.3.2 Oil. The base case forecasts oil price growth in the range of IPD because of stability in OPEC, no armed conflicts which disrupt oil production or transportation, and continued world-wide improvements in the energy efficiency of national economies.

The high case assumes that OPEC becomes very aggressive in restricting production, that members adhere to production quotas, that armed conflict causes moderate disruptions in world-wide distribution of oil, and that developing economies and growth of world-wide transportation spur growth in consumption, all of which leads to rapid price increases. Conversely, the low oil price case presumes that OPEC in unable to enforce production quotas, that non-OPEC countries increase production as a result of new discoveries and improved recovery from existing fields, all of which combines to continue the trend of recent years with declining prices.

4.3.3 Natural Gas. The base case presumes only moderate price increases as a result of continuing the trends of recent years. Production capacity continues to exceed demand leading to market price competition which constrains the rate of price increase.

The high case assumes a more rapid increase in price because technology ceases to improve, there is a gradual exhaustion of reserves with attendant declines in production coupled with continued growth in market demand. The low case forecasts a decrease in prices as a result of rapid exploitation of new technological innovations which dramatically increase recovery from existing well fields at reduced cost, discovery of major new reserve fields, and reduction in the cost of bringing new well into production. Under this scenario supply would significantly exceed demand

leading to actual decreases in price.

4.4 Modeling of Generation Unit Performance

Existing units are modeled with forced outage rates and heat rates for the near term based on recent historical data. The long term rates are based on a weighting of industry average data and expected or designed performance data.

4.5 Financial Assumptions

Expansion plans are evaluated based on Seminole's forecast of RUS guaranteed loan fund rates. The plans are tested with a sensitivity using financing rates forecast for funds other than RUS guaranteed funds in the event that the RUS funds are not available.

4.6 Integrated Resource Planning Process

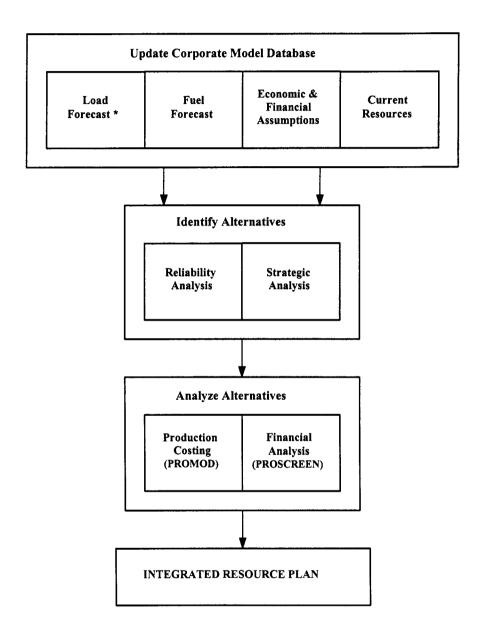

Seminole's primary long-range planning goal is to develop the most cost-effective way to meet its members' load requirements while maintaining high system reliability. Seminole's optimization process for resource selection is based primarily on total revenue requirements. For a not-for-profit cooperative, revenue requirements translate directly into rates to our member distribution cooperatives. The plan with the lowest revenue requirements is generally selected, assuming that other factors such as reliability impact, initial rate impact, and strategic considerations are neutral. Seminole also recognizes that planning assumptions change over time so planning decisions must be robust and are, therefore, tested over a variety of sensitivities. A flow chart of Seminole's planning process is shown on the next page.

The impact of demand-side management (DSM) and conservation is accounted for in Seminole's planning process by incorporating demand and energy reductions from conservation and DSM efforts into the load forecast. Additional impacts from Seminole's Coordinated Load Management Program are incorporated during the preparation of the Power Requirements Study.

Figure 3

Resource Planning Process

* The Load Forecasting process is detailed in Section 2.4, "Forecasting Methodology"

Given the nature of Seminole's power supply arrangements, reduction in peak demand does not usually affect the operation of Seminole's generating resources in the FPC area, but instead reduces the amount of PR purchases required from FPC.

4.7 Reliability Criteria

Seminole uses a minimum 15% system peak reserve margin as its primary reliability criteria. To meet this criteria, supply plans include adequate firm resources whose total capacity is 15% greater than Seminole's annual maximum demands. Beginning in the mid-80's, Seminole planned to a 1% Expected Unserved Energy (EUE) criteria which resulted in a reserves percent higher than the 15% minimum requirement. As Seminole's system and resources have grown and diversified, the two criteria haveconverged and reserve margin is now the driving criterion.

4.8 Strategic Concerns

In the current rapidly changing utility industry, strategic concerns are becoming increasingly important. Seminole presently, as in the past, has not quantified the financial impact of strategic concerns such as length of contracts, own vs purchase, etc. However, Seminole continues to evaluate a wide variety of options to meet future power requirements, as explained below under "Procurement of Supply-Side Resources".

4.9 Procurement of Supply-side Resources

Seminole will continue to use the all-sources RFP process as the primary means of filling its power supply needs. Seminole solicits proposals from turnkey contractors, utilities, independent power producers, qualifying facilities and power marketers as well as demand side options.

4.10 Transmission Plans

Seminole currently has no firm plans for transmission construction or upgrades subject to the Transmission Line Siting Act (TLSA). Seminole plans to build approximately 2.0 miles of double circuit 230 kV line to loop the Hardee to Lee Line into FP&L's Charlotte Substation. This project is for the purpose of improving the reliability of service. The table on the next page lists all 69 kV and above Transmission Line Projects planned by Seminole Member Distribution Cooperatives over the ten year planning horizon.

| Transmission Line Projects | | | | | | | | | | |
