

**BEFORE THE  
FLORIDA PUBLIC SERVICE COMMISSION**

**DOCKET NO. 130140-EI**

**TESTIMONY AND EXHIBIT  
OF  
PETER S. HUCK**

1 GULF POWER COMPANY

2 Before the Florida Public Service Commission  
3 Prepared Direct Testimony of  
4 Peter S. Huck  
5 Docket No. 130140-EI  
6 In Support of Rate Relief  
7 Date of Filing: July 12, 2013

8 Q. Please state your name, title, and business address.

9 A. My name is Peter Huck. I am employed by American Appraisal Associates,  
10 Inc. (American Appraisal), headquartered at 411 East Wisconsin Avenue,  
11 Milwaukee, Wisconsin, as Senior Manager of the electric and gas utility  
12 practice.

13 Q. Will you briefly describe American Appraisal and the nature of its services?

14 A. American Appraisal is a consulting firm employing more than 500 personnel  
15 in branch offices operating from major financial cities throughout Asia-  
16 Pacific, Europe, North America, and South America, including more than 10  
17 cities throughout the United States. American Appraisal has been a leader  
18 in the valuation profession since it was founded in 1896. Its services  
19 include utility depreciation rate studies, fair market value studies of both  
20 tangible and intangible property, business enterprise and capital stock  
21 valuations, insurance appraisals, property record studies, cost segregation  
22 studies, and other services centered on the valuation and management of  
23 property. American Appraisal's clients include public utilities, power  
24 generation and energy companies, industrial companies, financial  
25 companies, and public institutions.

1 Q. What is your educational and professional experience?

2 A. I received a Bachelor of Science degree in electrical engineering in 1972  
3 from Marquette University in Milwaukee, Wisconsin. In 1979, I received a  
4 degree of Master of Business Administration from Marquette University. In  
5 addition to formal courses, I attend and speak on a regular basis at  
6 seminars and programs relating to utility property valuation and utility  
7 depreciation rate studies.

8  
9 Since joining American Appraisal in 1973, I have been continuously  
10 engaged in consulting services to utilities and other concerns in the area of  
11 depreciation rate studies and appraisals. I have been responsible for  
12 studies of utility depreciation rates, fair market value appraisals of tangible  
13 and intangible assets, business enterprise and interests, and other work for  
14 electric and gas utilities, power generation companies, and other  
15 companies. I have also been responsible for many lifing studies of  
16 intangible assets for a variety of companies.

17  
18 I am registered as a professional engineer in the State of Wisconsin and an  
19 Accredited Member of the American Society of Appraisers (Machinery and  
20 Technical Specialties/Public Utilities). I have been a member of the  
21 American Gas Association Depreciation Committee. I am also a Senior  
22 Member in the Society of Depreciation Professionals.

23  
24 Q. What is your experience relative to depreciation rate studies?

25 A. Since joining American Appraisal, I have been active in depreciation rate

1 studies for a variety of utility and telecommunications companies. A partial  
2 list of my electric and gas utility clients includes Gulf Power Company (Gulf  
3 or the Company), Georgia Power Company, MidAmerican Energy, Central  
4 Illinois Light Company, Mississippi Power Company, Alabama Power  
5 Company, Oglethorpe Power Corporation, Indiana and Michigan Electric  
6 Company, SEMCO Natural Gas Company, ENSTAR Natural Gas  
7 Company, Piedmont Natural Gas Company, and Carolina Power & Light.  
8

9 Q. Have you previously presented depreciation rate studies before regulatory  
10 agencies?

11 A. I have testified before and/or submitted depreciation rate studies to the  
12 Federal Energy Regulatory Commission (FERC), the Rural Utilities Service,  
13 the Barbados Fair Trading Commission, and 13 state regulatory  
14 commissions, including Alabama, Alaska, Florida, Georgia, Illinois, Iowa,  
15 Kansas, Michigan, Minnesota, Mississippi, North Carolina, Ohio, and  
16 Virginia.  
17

18 Q. Why was American Appraisal engaged by Gulf?

19 A. We were engaged to conduct a depreciation rate study of the depreciable  
20 electric property of Gulf at December 31, 2013 (Study Date).  
21

22 Q. Will you describe your responsibility and participation in this assignment?

23 A. I personally participated in and directed all work performed by my firm,  
24 including the initial planning of the work, the office computations, the  
25 evaluation of the statistical analyses, and the preparation of Exhibit PSH-1.

1 Q. Are you sponsoring any exhibits in this case?

2 A. Yes, I am sponsoring Exhibit PSH-1, Gulf's Depreciation Study. The  
3 information contained therein is true and correct to the best of my  
4 knowledge and belief.

5  
6 Q. Will you summarize the scope of your testimony?

7 A. The depreciation study that I support sought to determine the appropriate  
8 book depreciation factors and rates to be applied to Gulf's depreciable plant  
9 to enable recovery of the plant investment, adjusted for net removal, over its  
10 remaining useful life. The study covers all of Gulf's depreciable electric  
11 plant in service as forecasted at December 31, 2013. My testimony covers  
12 the recommendations I have made to the Company with respect to  
13 depreciation (capital recovery) rates. The reported analyses, opinions, and  
14 conclusions outlined represent my impartial and unbiased professional  
15 analyses, opinions, and conclusions and those of American Appraisal. I will  
16 describe the study procedures and explain the results of the study.

17  
18 Q. Briefly, what are your recommendations?

19 A. I have advised Gulf to adopt revised depreciation rates based on my  
20 analysis of service life and net removal. The recommended depreciation  
21 rates for each Gulf plant account are detailed on pages 1 and 2 under Tab 4  
22 of the Depreciation Study, Exhibit PSH-1, which was prepared under my  
23 supervision. Comparisons of existing and recommended depreciation rates  
24 and annual depreciation based on plant and reserve balances as of  
25 December 31, 2013, are also on pages 1 through 3 under Tab 5 of the

1 Depreciation Study, Exhibit PSH-1. My recommendations are based on  
2 study and analysis undertaken for the purpose of developing reasonable  
3 and appropriate depreciation rates for the depreciable electric property of  
4 the Company as of December 31, 2013. The methods employed and the  
5 analysis made used accepted industry practice and were consistent with the  
6 depreciation methods and analysis that were used in Gulf's previous  
7 depreciation rate studies, which were filed with and approved by the Florida  
8 Public Service Commission (FPSC or Commission).

9  
10 Q. Briefly explain the purpose of depreciation.

11 A. In the accounting sense, depreciation is the recovery of the capital cost of  
12 property, allowing for net removal, at an orderly rate over the life of the  
13 property. In this context, the term "capital recovery" is frequently used in  
14 place of the term "depreciation." A principal reason for recognizing  
15 depreciation is to provide a systematic and rational reflection of the  
16 consumption of capital in cost of service or expenses when determining net  
17 income.

18  
19 The importance of full and timely capital recovery is obvious. For example,  
20 if the current rate of capital recovery of investment is lower than an  
21 appropriate rate, costs of serving current customers will be shifted to and  
22 paid by future customers. Conversely, if the current depreciation rate is  
23 higher than appropriate, current customers will be paying for the costs of  
24 serving future customers. Depreciation expense is an accepted element of  
25 utility cost of service, and appropriate capital recovery is accomplished by

1 periodic study and the inclusion of adequate depreciation expense in cost of  
2 service and the resulting rates.

3  
4 Q. What is the definition of depreciation you have used in this study?

5 A. My definition of depreciation is the same as that used by the FERC and the  
6 National Association of Regulatory Utility Commissioners. The definition of  
7 depreciation used is as follows:

8 Depreciation, as applied to depreciable electric plant,  
9 means the loss in service value not restored by current  
10 maintenance, incurred in connection with the  
11 consumption or prospective retirement of electric plant  
12 in the course of service from causes which are known  
13 to be in current operation and against which the utility is  
14 not protected by insurance. Among the causes to be  
15 given consideration are wear and tear, decay, action of  
16 the elements, inadequacy, obsolescence, changes in  
17 the art, changes in demand, and requirements of public  
18 authorities.

19 In the accounting sense, depreciation is the recovery of capital cost of  
20 property, allowing for net removal, at an orderly rate over the life of the  
21 property.

22  
23 Q. In the study performed for Gulf, did you consider all of the factors mentioned  
24 in the definition of depreciation?

25 A. Yes, I did.

1 Q. What method was used to calculate the depreciation rates?

2 A. As required under FPSC Rule 25-6.0436, depreciation rates were  
3 calculated for all accounts using the capital recovery method known as the  
4 Remaining Life Method, the same method employed in Gulf's previous  
5 studies.

6  
7 Q. Describe the Remaining Life method.

8 A. The Remaining Life Method, a straight-line depreciation method, recovers  
9 the original cost, adjusted for net removal and the depreciation reserve,  
10 over the average remaining life of the plant according to the formula:

11

$$\begin{array}{l} 12 \text{ Annual} \qquad 100\% + \text{Net Removal\%} - \text{Depreciation Reserve\%} \\ 13 \text{ Depreciation} = \frac{\hspace{15em}}{\hspace{15em}} \\ 14 \text{ Rate} \qquad \qquad \qquad \text{Average Remaining Life} \end{array}$$

15

16 The basic assumptions used in determining depreciation rates by the  
17 Remaining Life Method are that the property will be retired in a specified  
18 average remaining life and that the future amount of net removal, based on  
19 salvage and cost of removal, is known now. Of course, neither assumption  
20 can be verified until all of the property units have been retired.

21

22 While the remaining life is an assumption, it can be estimated with  
23 increased accuracy as the assets age because the date of ultimate  
24 retirement can be estimated with more certainty. Importantly, the  
25 Remaining Life Method is flexible in its ability to adapt to changed

1 conditions, consistent with the depreciation objective of providing full capital  
2 recovery on a timely basis. For these reasons, I recommend that Gulf's  
3 depreciation rates continue to be calculated based on the commonly used  
4 and accepted Remaining Life Method.

5  
6 Q. Briefly outline the steps in performing the depreciation study you are  
7 sponsoring.

8 A. The major steps involved in the depreciation rate study are the following:

9  
10 (1) Gathering of plant accounting data including vintage investment and  
11 dated retirements, annual additions, retirements, balances, and salvage and  
12 cost of removal amounts;

13  
14 (2) Processing the data against established retirement experience patterns  
15 using either computerized simulation or actuarial techniques to determine  
16 historical service life indications;

17  
18 (3) Evaluating the statistical retirement experience to determine service  
19 lives and retirement experience patterns (mortality dispersion curves);

20  
21 (4) Applying the life span analysis to Production plant locations to determine  
22 average remaining lives and depreciation rates;

1 (5) Considering other factors affecting depreciation, such as changing  
2 technology, regulatory and environmental requirements, and customer  
3 demands;

4  
5 (6) Determining the average remaining lives of the depreciable electric  
6 plant;

7  
8 (7) Analyzing net removal experience and determination of future net  
9 removal; and

10  
11 (8) Calculating the annual depreciation amounts and depreciation rates from  
12 the depreciation factors.

13  
14 The elements needed to make the depreciation rate calculation are a result  
15 of analysis and study. The study procedures outlined above, the collection  
16 of data, analysis of data, application of informed judgment, and calculation  
17 of depreciation rates are generally accepted practice in the utility industry  
18 and are the same procedures as employed for prior Gulf depreciation rate  
19 studies.

20  
21 Q. What data is gathered in the first step of the study?

22 A. The data gathered in the initial step of the study is certain property  
23 accounting data of each plant account or Production location. This property  
24 accounting data includes data used to determine historical life indications,  
25 such as annual additions and retirements or vintage investment and dated

1 retirements. Vintage investment of the Production locations is used in the  
2 life span method. Historical salvage and cost of removal data is obtained in  
3 order to analyze estimated future net removal. This data is the typical  
4 property accounting data used in electric depreciation rate studies, including  
5 Gulf's previous studies.

6  
7 Q. What is the goal of the second and third steps in performing the study,  
8 applying lifing techniques and determining service life indications?

9 A. The goal of the historical service life analysis is to determine the best  
10 estimate of future service life. Statistical analyses of actual turnover  
11 experiences with the depreciable assets provide indications of service life.  
12 This actual experience, along with other considerations related to the life of  
13 the assets (if appropriate), such as the nature of the assets and the life  
14 experiences of other utilities, form the basis of the determination of service  
15 life.

16  
17 The foregoing techniques are applied to all plant accounts except those of  
18 Production. The lives of Production plant locations are determined using  
19 the life span method, which I explain later in my testimony.

20  
21 Electric utility depreciation is primarily determined on a group basis because  
22 large numbers of property units with similar service lives (e.g., poles and  
23 conductors) can be grouped into particular asset categories. In contrast to  
24 item depreciation, where each asset is individually depreciated over a  
25

1 specified life, group depreciation is based on the use of average service  
2 lives for each group of assets.

3  
4 Q. How did you process the accounting data to determine historical service life  
5 indications?

6 A. When the retirement dates and the installation dates of depreciable assets  
7 were known, I used a standard actuarial technique, known as the  
8 Retirement Rate method, to determine historical service life indications.  
9 This actuarial data was available for Gulf's Transmission and General plant  
10 accounts, as well as the two substation plant accounts of Distribution. In  
11 the Retirement Rate method, the vintage investment and annual dated  
12 retirements are combined by age interval to develop retirements and  
13 investment exposed to retirement by age interval. Retirement rates are  
14 then calculated by age interval, which provide a measure of the probability  
15 of retirement by age interval. The observed survivor curve is developed  
16 from the retirements rates. Because the observed survivor curve seldom  
17 reaches zero percent surviving, a curve fitting analysis is applied that  
18 smoothes and completes the observed survivor curve. The curve fitting is  
19 made with the aid of a system of known retirement patterns called the lowa-  
20 type survivor curves. This system of known retirement patterns was  
21 developed at Iowa State University many years ago and is a generally  
22 accepted curve shape system within the industry. Based on the curve fitting  
23 analysis, the most applicable lowa survivor curve and average service life  
24 are selected for the property account.

25

1 Q. Was the actuarial method the only method you used to analyze historical  
2 service life indications?

3 A. No, it was not. When the retirement dates and the installation dates of  
4 depreciable assets were not known, I used a standard statistical technique  
5 known as the simulated method, specifically the Simulated Plant Record  
6 (SPR) method, to determine the historical service lives of the assets or  
7 asset categories. This is an accepted method in the industry. The SPR  
8 method of life analysis was applied to the majority of the Distribution plant  
9 accounts. These simulated techniques, which are sometimes called semi-  
10 actuarial methods, are commonly used and generally accepted life analysis  
11 techniques.

12

13 For purposes of Gulf's depreciation study, the specific SPR technique  
14 known as the balance method was relied upon. SPR methods are used to  
15 determine (i) historical service lives applicable to groups of assets and (ii)  
16 the pattern of retirement dispersion for a group of assets. Historical annual  
17 additions, retirements, and balances for the assets must be known to  
18 perform the balance method of SPR analysis.

19

20 In the balance method, the actual known book balances for a specific span  
21 of years, say 10 years, are used in a computer application to derive  
22 simulated balances over that same time period. Iowa-type survivor curves,  
23 which are well-recognized and widely used empirical representations of  
24 typical retirement patterns, are applied to the historical annual additions.  
25 Simulated retirements and resulting balances for each of the last 10 years

1 are then computed, allowing the analyst to determine a specific historical  
2 service life for each retirement dispersion pattern for a particular asset  
3 group. These simulated balances will equal total actual balances over the  
4 10-year period, even though for any given year the actual and simulated  
5 balances will not be exactly equal. This calculation is repeated for each of  
6 the several lowa-type curves and for different bands of balance years and  
7 study dates. The simulated balance method of life analysis gives  
8 indications of both historical service life and the pattern of retirement  
9 dispersion.

10  
11 Q. Do these analyses alone determine the service life of the property?

12 A. No, they do not. The computerized studies of past service lives are a vital  
13 first step to the depreciation rate study, but are not conclusive in and of  
14 themselves. The depreciation analyst must study the results and exercise  
15 informed judgment in selecting the best measure of past average service  
16 life and retirement dispersion. This judgment is then modified to reflect  
17 future conditions as they affect expectations in service lives. A pure  
18 mathematically driven procedure is never the solely correct approach to the  
19 life analysis of a utility property.

20  
21 Q. For purposes of Gulf's depreciation study, were all service lives and  
22 retirement patterns determined by the statistical analyses you have just  
23 described?

24 A. No. Certain property accounts do not have sufficient retirement activity  
25 either to make a quantitative analysis or to provide reliable indications of

1 historical life. In such instances, the depreciation rate characteristics have  
2 been determined from a consideration of the type and nature of the  
3 property, the average service life currently used for depreciation by the  
4 Company, the service lives experienced by other utilities, and comparison  
5 with depreciation characteristics of similar property, as well as giving due  
6 consideration to available historical life experience.

7  
8 Also, these standard quantitative analyses of historical life cannot be relied  
9 upon to give accurate life indications for Production. This property has  
10 location-life characteristics; that is, each location consists of a relatively  
11 large percentage of the total account investment, and retirements are  
12 usually small and interim in nature prior to the location's ultimate retirement.  
13 The Production plant accounts were, therefore, analyzed using a technique  
14 based on the forecast of the retirement date, known as the life span  
15 method.

16  
17 Q. Briefly describe the life span method, the analysis of which is the fourth  
18 stage in your performance of Gulf's depreciation study.

19 A. In a life span method, each location's life span is the time between the initial  
20 in-service date of a unit and its forecasted date of retirement. The primary  
21 life span of the plants units of Steam Production used in this analysis was  
22 65 years. The life span of Other Production's Smith Combined Cycle ("CC")  
23 was 40 years.

24  
25

1 The estimated retirement dates of the generating facilities used in the study  
2 were provided by the Company. I reviewed the retirement dates of Steam  
3 Production and Other Production provided to me in light of prior Gulf studies  
4 and our experience of Production plant life spans used in the electric utility  
5 and power generation industries and found them reasonable and  
6 appropriate for purposes of Gulf's depreciation.

7  
8 Remaining life of a generating unit is calculated by subtracting the date of  
9 the study from its estimated retirement date. The remaining life, however,  
10 must be decreased for future interim retirement activity, as we cannot  
11 presume that the total existing investment will remain in service until the  
12 ultimate retirement date. Future interim retirements were developed from  
13 the application of interim retirement rates, which were generally based on  
14 Company historical data. The interim retirement rate method used in this  
15 study is a generally accepted method used throughout the electric utility  
16 industry, including some electric utilities in Florida.

17  
18 Q. Turning now to the next step of the study, how did you establish the  
19 remaining life of the plant?

20 A. Remaining life is a function of service life retirement pattern and the  
21 distribution of the investment by year of installation, that is, the age of the  
22 investment. The remaining life for each plant account can be readily  
23 calculated from the actual or estimated age distribution of the property  
24 investment once the average service life is determined and the lowa-type  
25 curve of retirement dispersion is established.

1 For Production, remaining life was based on the difference between the  
2 retirement date of the investment and the Study Date, adjusted for interim  
3 retirement activity, in the life span method, as briefly described above.  
4

5 Q. What is the next step in the study process?

6 A. The next step is an analysis of salvage and cost of removal to determine  
7 the net removal for each account.  
8

9 Q. How did you go about making the net removal analysis?

10 A. Salvage and cost of removal experience of Gulf's depreciable property were  
11 studied as a percent of original cost of the plant retired. The data are  
12 examined for trends by computing annual percentages and percentages for  
13 selected bands of years. In general, the salvage and cost of removal data  
14 made available to me was on a historical basis from 1981 through the Study  
15 Date. For the Production locations, net removal used in the life span  
16 method was based on Gulf's net removal of interim retirement experience.  
17 The historical information and analysis specific to Gulf, the nature of the  
18 property, and knowledge of current industry experience and trends were  
19 used to develop the recommended net removal quantifications.  
20

21 Q. Were all the net removal amounts determined by the analysis you just  
22 described?

23 A. No, they were not. While my net removal analysis included net removal of  
24 interim retirements for Production, it excluded the net removal of the  
25 ultimate or final retirement of the plant units. That net removal was

1 determined separately in a dismantlement study prepared for Gulf using the  
2 method that was used by the Company in prior studies.

3

4 Q. Explain how the depreciation rate is calculated with the remaining life  
5 method.

6 A. Reference is made to the calculations shown on pages 1 through 42 under  
7 Tab 6 of the Depreciation Study, Exhibit PSH-1, for such a demonstration.  
8 When all the elements of the depreciation rate calculation are known, the  
9 annual depreciation rate for each account or location can be calculated.  
10 First, the investment amount to be recovered as of the Study Date and  
11 representing future depreciation is calculated as a percent. The amount to  
12 be recovered is the plant investment balance or 100 percent, plus the net  
13 removal percent, less the accumulated depreciation reserve percent as of  
14 the Study Date.

15

16 The depreciation rate on a straight line basis using the remaining life  
17 method is the amount to be recovered divided by the average remaining life.  
18 The recommended annual depreciation, as shown in Exhibit PSH-1, is then  
19 calculated by multiplying the plant investment balance by the depreciation  
20 rate.

21

22 The calculation of the depreciation can be demonstrated using Account  
23 362 – Station Equipment as shown on page 25 under Tab 6 of the  
24 Depreciation Study, Exhibit PSH-1. The amount to be recovered is the  
25 plant balance of 100 percent plus net removal of 8 percent less the

1 accumulated depreciation reserve of 25.2 percent, or 82.8 percent. That  
2 amount to be recovered of 82.8 percent is divided by the average remaining  
3 life of 36.2 years to result in the recommended depreciation rate of 2.3  
4 percent, rounded. The depreciation of Account 362 is then calculated by  
5 multiplying the plant balance of \$239,656,818 by depreciation rate of 2.3  
6 percent, or \$5,512,107.

7  
8 **Q. Briefly, what are the results of your recommendations?**

9 **A. My overall depreciation recommendations are summarized on pages 1  
10 through 3 under Tab 5 of the Depreciation Study, Exhibit PSH-1.**

11  
12 The difference in Steam Production depreciation is largely due to Plant  
13 Crist. Its recommended depreciation rate is greater than the present rate  
14 because of the combined effects of the substantial increase in plant balance  
15 of approximately \$360,000,000 since the prior study that will have a  
16 relatively shorter life for its recovery, effects of the interim retirements, and  
17 an increase of 5 percentage points in the net removal of interim retirements.

18  
19 The recommended depreciation rate of Smith CC was also significantly  
20 greater than the present depreciation rate. Its depreciation rate increase  
21 was largely due to the effects of interim retirements and its relatively lower  
22 accumulated depreciation reserve.

23  
24 The recommended depreciation rates of Transmission, Distribution, and  
25 General are largely similar to the present rates. The recommended average

1 service lives of the accounts of these functional groups were increased by  
2 one to two years on average from the prior study. Recommended net  
3 removal was typically somewhat more negative than in the prior study,  
4 which tends to offset the increase in average service lives.

5  
6 Q. Why should the Commission accept the depreciation rates you recommend  
7 for Gulf?

8 A. The depreciation rates I have recommended are required to recover the  
9 total cost of plant, allowing for net removal, over the remaining useful life of  
10 the plant. The recommended depreciation rates, based on an accepted  
11 capital recovery method, are a result of our analysis and study of the facts  
12 and conditions known to be in existence at the time of the study.

13  
14 The techniques employed to derive the analyses and to calculate  
15 depreciation are accepted practices. The depreciation methods,  
16 techniques, calculations, and rates are consistent in all material respects  
17 with the previous Gulf depreciation rate studies, which have been approved  
18 by the Commission. The recommended depreciation rates are reasonable  
19 and appropriate for Gulf's capital recovery.

20  
21 Q. Does that conclude your testimony?

22 A. Yes, it does.  
23  
24
